WAR NOTICES

Petrol Rationing

As a result of further representations made by the British Medical Association to the Petroleum Department all Divisional Petroleum Officers have been reminded of the necessity of urgently reviewing the essential requirements of individual medical practitioners. There is no foundation for the suggestion that the basic supplementary ration already issued is all which the Divisional Petroleum Officers have power to grant. Every effort is being made to secure a considerable increase in the basic supplementary ration in order that the cases calling for special consideration by the Divisional Petroleum Officers, in consultation with the Association's advisers, may be reduced to manageable proportions. Any medical practitioner who needs for professional purposes more petrol than he has already received should make a further application to the Divisional Petroleum Officer, giving exact particulars of his essential requirements. He should *not* address applications or correspondence to the Association's advisory officer unless he has been invited to do so.

It is reported that a very large number of medical practitioners have failed to send their registration books with their original applications. It therefore appears necessary to stress the importance of medical applicants complying strictly with the procedure laid down. It must be emphasized also that in present circumstances medical practitioners, like other car users, should exercise the utmost economy possible in their consumption of petrol. An unreasonable attitude on the part of a few applicants may well prejudice the success not only of their own applications but also of the legitimate claims of large numbers of their colleagues.

First-aid Posts

the time this paragraph appears a deputation from the iation, consisting of representative practitioners and al officers of health, will have discussed with the Minister ealth the whole question of the employment and remuneration of medical practitioners at first-aid posts. The matter being pressed with vigour and expedition.

Unaccompanied Children

Minister of Health has informed the Association that unable to accept the suggestion that the unaccompanied children's scheme should be extended to cover accompanied children and others officially evacuated. In his view existing facilities, augmented as may prove necessary, should be used for the treatment of these classes of person.

The Association has pointed out to the Minister that in the majority of areas the public assistance medical service is provided by part-time salaried medical officers whose salaries are often inadequate and are in any case in respect of the normal public assistance population of the area. The Association has urged the Minister to advise local authorities in reception areas to augment the public assistance medical arrangements, preferably by the adoption, at least for the persons in this group, of the open choice system.

The Minister's reply to this suggestion is now awaited. When it is available, Local Emergency Committees will be advised as to the appropriate local action.

The Definition of the Unaccompanied Child

It has now been ascertained that every child who is boarded by the Government with a householder who receives payment for board and lodging at the rate of 10s. 6d. or 8s. 6d. per child is covered by the existing unaccompanied children's scheme.

Changes

Any medical practitioner who moves from the area of one Local Emergency Committee to that of another is asked to inform the Local Emergency Committee of the area to which he goes of his new address immediately on arrival.

Any practitioner who wishes to alter his statement of intention of service in view of the alteration of the situation since he made his return should intimate the change to this office.

CENTRAL EMERGENCY COMMITTEE
(Central Medical War Committee),
British Medical Association House,
Tavistock Square, W.C.1.

The annual meeting of the National Association of Insurance Committees, which was to have been held in London on October 12, 13, and 14, has been postponed on account of the war.

British Medical Association

SPECIAL COUNCIL MEETING

A special meeting of the Council of the British Medical Association was held at Tavistock Square, London, on September 27. Mr. H. S. Souttar (Chairman of Council) presided, but as most of the matters arose on reports of committees of which Mr. Souttar is chairman, the chair was taken during a considerable part of the proceedings by Dr. H. G. Dain, Chairman of the Representative Body. The others members present were:

Dr. J. W. Bone (Treasurer), Dr. Peter Macdonald (Deputy Chairman of Representative Body), Sir Kaye Le Fleming (Immediate Past Chairman of Council), Mr. N. Bishop harman (Immediate Past Treasurer), Dr. R. H. Balfour Barrow, Professor R. J. A. Berry, Mr. L. R. Broster, Professor A. H. Burgess, Mr. V. Zachary Cope, Mr. W. McAdam Eccles, Dr. A. W. Gardner, Dr. R. G. Gordon, Dr. F. Gray, Dr. E. A. Gregg, Lieutenant-Colonel W. L. Harnett, I.M.S. (ret.), Dr. E. W. Lewis, Mr. E. Lewis Lilley, Sir Ewen Maclean, Dr. O. Marriott, Dr. J. Middleton Martin, Dr. J. C. Matthews, Dr. H. B. Morgan, Mr. R. L. Newell, Dr. W. Paterson, Professor R. M. F. Picken, Colonel A. H. Proctor, Wing Commander T. S. Rippon, R.A.F.M.S. (ret.), Dr. H. Robinson, Dr. F. A. Roper, Mr. R. Scott Stevenson, Dr. W. E. Thomas, Dr. S. Wand, Mr. N. E. Waterfield, Dr. W. N. West-Watson, Mr. A. Hedley Whyte, Dr. W. G. Willoughby.

Medical Treatment of Evacuated Children

Mr. Souttar, as chairman of the Central Emergency Committee, reported that agreement had been reached between the Association and the Ministry of Health on the financial arrangements for the medical treatment of children transferred to reception areas under the Government scheme. The arrangement applied to each child, not accompanied by a parent, who was billeted upon a householder. A sum of money calculated at the rate of 10s. for every such child would be placed at the disposal of each Local Emergency Committee in a reception area to meet the cost of the provision of medical attendance. This money would be disbursed to practitioners undertaking the treatment of children covered by the scheme on a basis devised and approved by the Local Emergency Committee concerned. The amount paid was intended to cover the cost of attendance and provision of medicine. The allocation of medical men for this work was a matter for the decision of the Local Emergency Committees, with whose autonomy the Central Committee in no way interfered. The sum available would be considerable, and, he thought, sufficient. The question of the accompanied children was under discussion with the Ministry. A difficult matter concerned the transfer of practitioners from evacuation to reception areas. Some practitioners were left virtually without their practices. These would be asked to register with their Local Emergency Committee, which would communicate to the Central Emergency Committee the names of those available for transfer to other areas, and the emergency committees in the reception areas would communicate their detailed needs for additional medical personnel also to the Central Committee.

In reply to Dr. Peter Macdonald, Mr. Souttar said that the sum of 10s. a year was the capitation rate per child, *not* per case treated. Dr. Waterfield considered that the rate was entirely inadequate, and he hoped that it had been made clear to the Ministry that in accepting this fee general practitioners considered themselves to be making some contribution to the national situation. Dr. Lewis, speaking from experience of a reception area, said that it was essential that the accompanied children should be on the same footing in this respect as the unaccompanied. In many cases in the absence of any arrangement for remuneration for the accompanied children, the only resort was to public assistance. Dr. Dain said that all these points had been brought to the attention of the Ministry. If a person wished to move from one area to another, the provision of medical services was the responsibility of the person concerned. Only when people were moved by their local authority could the responsibility be undertaken for them; the authorities could not be expected to assume responsibility for those who moved themselves. Sir Kaye Le Fleming also said that all these difficulties had been brought before the Central Emergency Committee, but he hoped the Council would not fail to recognize that a very great concession had been obtained, not at all easily, in the shape of this rate of payment for the unaccompanied children. He was doubtful how far that could be extended to others.

Petrol Rationing

A lengthy discussion took place on the question of petrol rationing for practitioners. Dr. Dain said that the first allocation of extra petrol supply was an immediate allotment to furnish relief while a further claim was being made. It was obvious that some such mechanical method of distribution would have to be put into force, but this did not mean that it was to be considered permanent. The situation was difficult at the moment, but the petrol distribution organization had to be given time to find its feet. Medical practitioners were placed in the highest category of priority and received the largest petrol allowance per h.p. on their cars.

Dr. Lewis Lilley said that he had received an intimation to the effect that the allowance made to him was "the maximum amount allowed under the regulations," and it was only 54 per cent. of his maximum consumption. Dr. Wand said that it seemed to him that the divisional petroleum officers had no real power whatever. Their job was almost mechanical. They had a fixed formula upon which they were bound to work—a formula decided by the Mines Department. There seemed to be two main problems. One was that the doctor who had only one car was penalized in comparison with the doctor with two or three cars. Again, the distribution was so mechanical as to be absurd. No discrimination was made between the rural and the urban practitioners. Unless some arrangement was made centrally with the Ministry it was not clear how the situation could be relieved. Many doctors in Birmingham would be out of their month's supply of petrol in two and a half weeks, and that was an urban area; things might be expected to be much worse in a rural one. It would be a great help if in some way it could be made known to the profession that the situation would shortly be rectified. It was only a question of petrol for the necessary travelling in connexion with practice. The ordinary motor-car user, maintaining his car for pleasure, had a petrol allowance which would suffice for two hundred miles a month. The doctors were not asking for that extra two hundred miles over and above their professional allowance. He thought that strong representation should be made from the Council for some definite statement which might be broadcast and would reassure the profession throughout the country.

Professor Picken, as one who was being "inundated with complaints" on this matter, agreed with Dr. Wand in this respect, that there was need for further central negotiation for the raising of the standard supplementary ration. This ration, which was being given to virtually all practitioners, was not sufficient for the average man, let alone the man wh[illegible] did more than the average mileage. It was not sufficient i[illegible] the town and obviously not nearly sufficient in a coun[illegible] practice of any kind. He thought that if the average med[illegible] man asked for more he should be given it automatica[illegible] unless his demand was obviously unreasonable. Only w[illegible] there was an excessive demand should any question be rai[illegible] about it. There was available in the office of the Associa[illegible] a record of the mileage of typical practitioners in diffe[illegible] parts of the country. The variation in mileage was, of cou[illegible] enormous, but, taking the average, the man in town in [illegible] ran his car for about 168 miles a week, and the av[illegible] man in a difficult country area about 250 miles a week. [illegible] present allowance permitted, as he learned on the basis of a number of returns he had had before him, of about

150 miles a week being done. It was just not enough for the average town practitioner and a long way short for the man in country practice. Dr. Wand had suggested that a man who had more than one car was sometimes at a distinct advantage. This was not uniformly so, but some men with two cars were getting a fair allowance for the two although they did not do more mileage than another man who had only one car. The principle should obviously be rationing by practice and not rationing by car. It was not quite true that the petroleum officer had no powers. The officer in South Wales had told him that when things settled down it was his intention to take individual cases on their merits and if necessary consult the medical adviser.

Mr. Zachary Cope pointed out that the petroleum controllers had had a very big task put upon them. He believed that the controller for London intended to do all that he could for the practitioners in his area, and he thought the same was true of other districts. Many of the points which at present caused difficulty would be put right as time went on. It should not be supposed that the peace-time ration of petrol was the necessary criterion for war time, even for a doctor, because some doctors carried on three or four surgeries at different places, and in his view it was reasonable to economize by some interchange with other practitioners so as to entail less travelling to distant patients.

Dr. Lewis said that he had applied for his petrol allowance in the usual way and got six gallons a month. He applied for a supplementary ration only on one of his two cars, not thinking it justifiable to apply on both, and, taking the basis of 25 miles to the gallon, which was fairly reasonable, he found that he had only received half the allowance for which he had claimed—in other words, he had to make do for two months with the petrol which he would have needed for one month.

Sir Kaye Le Fleming said that there was sufficient evidence from the discussion of great dissatisfaction over this question, and it would be taken up very seriously again. He felt confident that practitioners would all get the petrol they needed when the machinery had had time to settle down.

The Secretary said that obviously the thing to do was for the Association to approach the Mines Department on the ground that the ration already given to practitioners was too low, and also on the ground that following this standard ration individual consideration must be given to the claims put forward. It must not be overlooked, of course, that there were men who put in excessive claims, and there must be some check upon them. The office had been in almost daily communication with the Department of Mines and was prepared to do all that it could to get a reasonable ration for the doctor.

Medical Work at First-aid Posts

Mr. Souttar, again reporting for the Central Emergency Committee, said that it had been agreed with the Ministry that the appropriate rate of payment for doctors at first-aid posts in war time was one and a half guineas per session of not more than two hours' duration, and three guineas for a session exceeding three hours, subject to a total payment of not more than three guineas in respect of any one day. A sessional fee was payable on all occasions when a doctor was required to attend in consequence of an air raid warning. The sessional fee ran from the time of his arrival at the post. The question of an appropriate fee for practitioners who were in charge of first-aid posts had been raised with the Ministry. It was a matter of some difficulty. Such practitioners were expected to train the personnel and to supervise the organization of the stores, and no satisfactory provision had so far been made for this work. The sum arranged originally before the war was twenty guineas per annum, but if a man had to go repeatedly to train his staff and exercise other supervision that sum was inadequate and did not meet the present emergency at all.

Professor Burgess said that the stipulation that the session should run from the time of the arrival of the doctor at the post was all very well for first-aid posts but was inapplicable to doctors attached to emergency civil hospitals, some of which were twenty or twenty-five miles out. If such men were summoned to attend in the middle of the night and had to journey through darkened streets disorganized by air raid conditions they might spend at least an hour in getting to their hospital. He hoped that the analogy of the first-aid post would not be taken in the emergency hospital scheme.

Mr. McAdam Eccles said that most if not all of the medical officers who were giving what was really part-time service on a sessional basis at first-aid posts were quite satisfied with the proposed remuneration. One difficulty was experienced by some medical officers in actually reaching a first-aid post on a warning being given. One of the chief officers—a woman—in the first-aid post with which he was associated, on proceeding to the post after a recent warning (it was fortunately not followed by a raid), was prevented by the air raid warden from going through the streets, and despite her protest was kept in the police office for two hours until the "all clear" was sounded. The position might be met by the issue of steel helmets to all medical practitioners attached to first-aid posts, the helmet being not only a protection but a passport. The part-time officers were also supposed to help in the instruction of the staff, but they were informed by the authorities in his district that if they attended for that purpose no fee would be payable. It was only on an actual air raid warning that they could make a remunerative attendance.

The Secretary said that he had been in almost daily communication with the Ministry of Health on this subject and he was still trying to obtain a satisfactory statement. No provision whatsoever had been made for the payment of men engaged in instructing the personnel attached to first-aid posts or in getting the posts ready. The Ministry had been informed that it was imperative to make some arrangement, and it had been suggested to the Ministry that a meeting of medical officers of health for the metropolitan boroughs should be called, when some of those actually doing this work would be in attendance and be able to state the position.

Dr. Gray said that he hoped he was exaggerating the importance of the first-aid posts. It was possible that such posts would have nothing to do at all. In an industrial area it was considered that either they would have no work whatever to do or, on the other hand, would have a very large number of casualties—anything up to 500. The problem was not merely to give first-aid treatment but to give it to a large number of people in a sufficiently short time. Even if cases could be dealt with at the rate of one a minute in each of the two sections, male and female, a casualty list of 500 could not be got through in less than four hours, which was much too long. At the moment in the absence of air war a splendid opportunity presented itself of getting this organization into perfect working order. At the beginning of the war there was no organization at all, in some cases the buildings were unsatisfactory, in others the staffs had no working unity. Some doctors had been putting in a 100-hour week in order to get the first-aid staffs organized to do this work. Yet doctors were being told that they were not required to come to the posts except to attend casualties in an air raid. Even after the organization had been got into smooth working order it would still be necessary for someone—he hoped a doctor—to keep it up to concert pitch, and that would mean one short session per week per shift, including the shift which carried on from midnight until 8 a.m. It was also very disadvantageous if the lay staff, however well trained, was expected to stand by during an air raid and the doctor was not present. It seemed to him essential that there should be a doctor in real charge of such posts—not merely in nominal charge, coming along after a raid.

The Secretary read a letter which he had addressed on September 15 to the Ministry of Health on the subject of rate of payment for practitioners designated as being in charge of the nursing and first-aid personnel at first-aid posts, pointing out the quite different state of affairs which had existed at those posts since war began, necessitating almost continuous attendance by the medical officers attached, so that it was quite obvious that the peace-time arrangement of twenty guineas per annum was unsuitable. It was suggested in the letter that the sessional fee of one and a half guineas should apply when attendance was given for organization and instructional purposes, or, alternatively, that a substantial retaining fee should be paid.

This letter was approved as expressing the mind of the Council on the subject.

Specialists and the Services

It was reported that it had now been established that a practitioner appointed as a specialist in the R.A.M.C., within the authorized establishment, would be granted the rank of major, and the rank of squadron-leader would be granted to a practitioner similarly appointed in the R.A.F. Volunteer Reserve. The position of specialists entering the Royal Navy was under consideration.

Mr. Hedley Whyte pointed out that there were many specialists serving with the rank of captain or lieutenant. It was true that these men had joined the Territorial Army at a time when no specialist appointments were available. The Local Emergency Committee in his area did not appear to have taken it into consideration that there might be specialists serving who would consider transfer if they were given the opportunity. He had no doubt that in course of time these anomalies would be put right, but the Central Emergency Committee might bring to the notice of the appropriate authority the fact that these men were serving in the junior ranks and should receive promotion because of their specialty.

The Secretary explained that the Association was asked to get a number of specialists for the R.A.M.C. and was told by the Army authorities that when they were posted to the specialist positions at a hospital—and they were all requisitioned on that footing—they would have the rank of major. So far as the Territorial Army was concerned he had raised the question at the War Office and had been told that officers at the Territorial hospitals would be treated in exactly the same way as in the R.A.M.C.; but a number of men had gone into the Territorial Army simply as medical officers to battalions and were now contending that they should be used in a specialist capacity. When a further demand came from the Army for specialists it would be necessary to look through the list of officers who had been in the Territorial Forces and extract those who had claims to be specialists. Then the War Office would be asked, before recruiting civilians, to take some of the men who were in the Territorial Army. That was what was proposed to be done, and he knew that the Army authorities were anxious to do some such combing-out as Mr. Hedley Whyte had indicated.

Dr. R. G. **Gordon** referred to a point raised in the report in connexion with the transfer of practitioners from evacuation to reception areas, in which it was stated that "an incoming general practitioner employed whole-time should be remunerated at a rate not less than that which would obtain if the practitioner in question joined the Services or became a medical officer in the Emergency Medical Service. This minimum whole-time standard is £550 a year, plus £100 where board and lodging are not provided." In the *Supplement* of September 9 it was stated that this arrangement was in order to bring such practitioners in relation with the corresponding rank they would have had had they been commissioned. A practitioner had put the question to him, supposing he required an assistant, who would be a fairly recently qualified medical woman, whether he would be expected to pay her £650 a year when the ordinary lieutenant in the R.A.M.C. received a great deal less.

The Secretary said that the object in the main was to send to the reception areas those doctors who had had their practices taken away from them in the evacuation areas. In forming this scale for the Emergency Hospital Service and for many other services the minimum of £550 a year was considered fair payment. The lieutenant's pay with emoluments amounted to over £500 a year. It had to be remembered that the practitioner himself was asked to enter into a bond that he would not continue to practice in that area. They were doing their best to protect the practices which remained, and it was thought that this arrangement was a fair one to the doctor who had gone into a different area and whose practice in his old area had largely disappeared.

The Report of the Central Emergency Committee was approved.

Association Business during War Time

The Council agreed to appoint an executive committee to conduct the business of the Association at such times as it was not found practicable to hold meetings of the Council, the committee to consist of the following: the Chairman of Council (Mr. H. S. Souttar), the Chairman of the Representative Body (Dr. H. G. Dain), the Treasurer (Dr. J. W. Bone), the Deputy Chairman of the Representative Body (Dr. Peter Macdonald), all *ex officio,* together with Sir Kaye Le Fleming, Mr. N. Bishop Harman, and Dr. R. G. Gordon, and the Secretary and Editor in attendance, other persons to be called in consultation at the discretion of the Chairman of Council.

Professor Picken said that he was unwilling to entrust to a very small body, however highly competent, the Association's affairs over what might be a lengthy period, without the Council being called together. Very grave issues were likely to arise in relation to medical practice as a result of the war, and the state of affairs which would come about either during the war itself or most certainly after it must be borne constantly in mind. Important matters in relation to public health were also likely to come forward, and he would not care to see these handled by a small group who had only a limited knowledge of the problems. He thought that this question had to be considered from a wider outlook than that of mere immediate efficiency.

After other members of the Council had spoken an addendum was agreed to that the Council should be called together at least twice in the year as well as on other occasions when the Executive Committee deemed it necessary.

The decision of the provisional executive committee to cancel the Annual Meeting to be held in Birmingham in July, 1940, was reported and approved. It was stated that expenditure in Birmingham had already been incurred to the amount of about £300, and it was agreed that the Association should defray this expenditure in full.

The Chairman of Council mentioned certain important decisions which had been arrived at with regard to the new buildings of the Association as affected by the present crisis.

In view of the possibility that a meeting of the full Council might not be called in November, when the Board of Directors of the *British Medical Journal* came up for reappointment, the present meeting decided to reappoint the Board for a period of one year as follows: Professor R. J. A. Berry, Dr. R. G. Gordon, Dr. J. C. Matthews, Dr. H. Robinson, and Mr. R. Scott Stevenson.

Notification of Measles and Whooping-cough

The Secretary read a letter from the Ministry of Health stating that it was proposed to make measles and whooping-cough compulsorily notifiable during the present emergency and suggesting that a notification fee of one shilling instead of two shillings and sixpence be paid to practitioners.

Professor Picken said that if information was desired about the incidence of measles it could be obtained by notification of the first case in a house, for which a fee of two shillings and sixpence was ordinarily paid. This assumed, however, that the local authorities had sufficient staff to go round and make inquiries, otherwise they would not get the information desired. It was therefore thought it would be cheaper to make every case of measles notifiable so that the information would come to them without any need for searching or for maintaining public health staff for that purpose. The question was why this economy should be exercised at the expense of the profession.

Dr. Waterfield, Dr. Gray, Dr. Wand, and others expressed the view that the medical profession should not undertake such notification except at the regulation fee of two shillings and sixpence, and a motion to that effect was carried.

This concluded the business before the Council.

British Medical Association

Sir Charles Hastings Clinical Prize

The Sir Charles Hastings Clinical Prize, which consists of a certificate and a money award of fifty guineas, is again open for competition in respect of 1940. The following are the regulations governing the award:

1. The prize is established by the Council of the British Medical Association for the promotion of systematic observation, research, and record in general practice; it includes a money award of the value of fifty guineas.

2. Any member of the Association who is engaged in general practice is eligible to compete for the prize.

3. The work submitted must include personal observations and experiences collected by the candidate in general practice, and a high order of excellence will be required. If no essay entered is of sufficient merit no award will be made. It is to be noted that candidates in their entries should direct their attention mainly to their own observations in practice rather than to comments on previously published work on the subject, though reference to current literature should not be omitted when it bears directly on their results, their interpretations, and their conclusions.

4. Essays, or whatever form the candidate desires his work to take, must be sent to the British Medical Association House, Tavistock Square, London, W.C.1, not later than December 31, 1939. The prize will be awarded at the Annual General Meeting of the Association to be held in July, 1940.

5. No study or essay that has been published in the medical press or elsewhere will be considered eligible for the prize, and a contribution offered in one year cannot be accepted in any subsequent year unless it includes evidence of further work. A prizewinner in any year is not eligible for a second award of the prize.

6. If any question arises in reference to the eligibility of the candidate, or the admissibility of his or her essay, the decision of the Council on any such point shall be final.

7. Each essay must be typewritten or printed, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto, and enclosing the candidate's name and address.

8. The writer of the essay to whom the prize is awarded may, on the initiative of the Science Committee, be requested to prepare a paper on the subject for publication in the *British Medical Journal*, or for presentation to the appropriate Section of the Annual Meeting of the Association.

9. Inquiries relative to the prize should be addressed to the Secretary.

Meetings of Branches and Divisions

BRITISH GUIANA BRANCH

At a clinical meeting of the British Guiana Branch, held at Georgetown on June 28, with Dr. R. T. BAYLEY in the chair, the following cases were shown.

By Dr. M. O. LUCK: Stone in the ureter; ectopic kidney; and a case in which a provisional diagnosis of Addison's disease had been made. All three were in adult male Africans.

By Mr. D. I. C. FINLAYSON: (1) Deep jaundice in a man of mixed race. Shadows suggestive of gall-stones were demonstrated by *x* rays. In view, however, of the patient's advanced age and extreme emaciation the possibility of coincident carcinoma was discussed. At subsequent operation no gall-stones were found, but a malignant process in the hilar region probably arising from the hepatic ducts. Mr. Finlayson also showed (2) a pathological specimen of a small rounded tumour in the lumen of the ileum which gave rise to intussusception in an adult male African. Histological examination of the tumour showed it to be a papilloma of simple nature but with certain areas of infiltration suggestive of a possible early malignant change.

By Dr. E. G. H. PAYNE: Generalized adenitis of syphilitic origin in an adult male African (syphilitic adenopathy).

By Dr. B. B. G. NEHAUL: (1) Herpes zoster in an African female aged 42. Three weeks previously she had fallen down and hit her chest, and later suffered from pain at the site. She had applied a liniment; subsequently vesicles appeared occupying a band-like area about three inches wide across the lower part of the left side of the chest from the mid-line in front to the mid-line posteriorly, corresponding to the distribution of the seventh and eighth intercostal nerves. The patient had attributed the vesicle formation to the liniment. (2) Psoriasis in an aboriginal Indian aged 30.

Dr. P. A. CLEARKIN, Government pathologist, demonstrated the following specimens: (*a*) Tubal pregnancy which went to full term. The right tube formed a sac for the foetus and membranes without rupturing. The uterus was about the normal size. The os was not dilated. The patient passed into labour and died. At necropsy the foetus was found filling the abdomen. A perinephric abscess was found on the right side. (*b*) Heart in a fatal case of gonococcal endocarditis. Ante-mortem blood culture showed a growth of a small Gram-negative diplococcus which gave all the cultural reactions of the gonococcus. The aortic valves showed vegetations, and one of the cusps was perforated. An infarct was found in the upper pole of the left kidney. (*c*) Tuberculous lung: The sputum was negative for tubercle bacilli ante mortem, but showed numerous moniliform organisms. Few tubercle bacilli were seen in smears taken post mortem. Histological examinations showed typical tuberculous lesions. (*d*) Acute necrosis of the liver. (*e*) Enlarged spleen (malarial); weight 2½ lb. (*f*) Horshoe kidney. There were no symptoms ante mortem; it was discovered at necropsy on an East Indian female. The two kidneys were joined at the lower poles by a band of renal tissue. (*g*) Massive pulmonary collapse. The oesophagus at the level of the bifurcation of the trachea was constricted by a hard fibrous ring which reduced the lumen to the diameter of a narrow probe. There was no ulceration, and only a few regional lymph nodes were affected. No metastatic deposits in other organs were noted. Histologically the growth was a scirrhous carcinoma. Right lung solid, dry, and airless. All the veins were distended and filled with blood clot. Left lung apex collapsed. The cause of the collapse was doubtful in view of the small size of the carcinoma of the oesophagus.

SURREY BRANCH

At the annual meeting of the Surrey Branch, held at Richmond on June 28, the following officers were elected:

President, Dr. D. Stark Murray. *Past-President*, Dr. J. Hussey. *President-Elect*, Dr. G. D. Laing. *Honorary Secretary and Treasurer*, Dr. P. V. Fry.

About 120 members and their guests attended a luncheon at Ham Common at the invitation of the Richmond Division. The MAYOR OF RICHMOND welcomed the Branch members to Richmond and gave his speech of welcome at the luncheon. After the toast of "The King" the CHAIRMAN OF THE RICHMOND DIVISION proposed "The Guests," and the MAYOR OF BARNES responded. The annual meeting followed, and Dr. STARK MURRAY was inducted as president. He then gave his address on "The Scientific Approach to Medical Problems." He spoke of the science as compared with the art of medicine, of the need for scientific investigation and inquiry as essential to correct diagnosis, and the increasing need for a fuller understanding by general practitioners of the usefulness of the work of the clinical pathologist. The scientific approach was essential not only to the problems of clinical medicine but to larger medical problems, and would lead to a consideration of, for example, environment in relation to illness, the relationship of preventive and curative measures, the extension of team-work within the profession, the assessing and trial of new preparations, the carrying out of research by the general practitioner, and the advancement of the scientific principle throughout the profession. A hearty vote of thanks was unanimously accorded Dr. Stark Murray for his address.

After the meeting members and their guests went to the Star and Garter Home, Richmond Hill, where they were welcomed by the commandant, Lieutenant-Colonel E. L. Gowlland, who gave some interesting information about the formation and functions of the home, and who permitted the visitors to view the premises. The Richmond Division provided tea and refreshments at the home, and a very successful day was brought to a conclusion. The retiring president, Dr. Hussey, thanked the Division on behalf of the Branch for its hospitality.

YORKSHIRE BRANCH: HUDDERSFIELD DIVISION

At the annual meeting of the Huddersfield Division, held on July 18, the secretary's annual report was considered and approved. The agenda of the Annual Representative Meeting was considered and the representative instructed accordingly. The Irving golf cup was presented to the winner, Dr. D. Guest. The officers and committee for the ensuing year were elected.

LIBRARY OF THE B.M.A.

It is requested that members of the B.M.A. proceeding on Service will return all library books and journals.

The Library service is one of the privileges available to members of the British Medical Association resident in Great Britain and Ireland. Full particulars will be forwarded on application to the Librarian, B.M.A. House, Tavistock Square, London, W.C.1.

The following volumes were added to the Library during August, 1939:

Beaumont, W.: Diathermy. 1939.
Bergey, D. A., *et al.*: Manual of Determinative Bacteriology. Fifth edition. 1939.
Berry, R. J. A.: Your Brain and its Story. 1939.
Bertho, A., and Grassman, W.: Laboratory Methods of Biochemistry. 1938.
Bogert, L. J.: Nutrition and Physical Fitness. Third edition. 1939.
Brocq-Rousseu, D., and Roussel, G.: Le Sérum Normal. Propriétes Physiologiques. 1939.
Browne, F. J.: Antenatal and Postnatal Care. Third edition. 1939.
Carraro, N., and Wigmeister, I.: L'Ipertrofia della Prostata. 1938.
Clark, K. C.: Positioning in Radiography, 1939.
Clark, Le Mon.: Vaginal Diaphragm. 1939.
Cowdry, E. V. (Editor): Problems of Ageing.
Fluhmann, C. F.: Menstrual Disorders. 1939.
Hirschfeld, J.: Toothbrush: Its Use and Abuse. 1939.
Iriarte, D. R.: Trabajos Cientificos. 1937.
Johnston, T. B.: Synopsis of Regional Anatomy. Fourth edition. 1939.
McGregor, A. L.: Synopsis of Surgical Anatomy. Fourth edition. 1939.
Megroz, R L.: Dream World. 1939.
Muir, E.: Leprosy, Diagnosis, Treatment, and Prevention. Sixth edition. 1938.
Pertsov, I. A. (Editor): Health Resorts of the U.S.S.R. 1939.
Ranson, S. W.: Anatomy of the Nervous System. Sixth edition. 1939.
Rice, T. B.: Textbook of Applied Microbiology and Pathology. Second edition. 1939.
Roger, H., and Poursines, Y.: Les Méningo-Neurobrucelloses. 1938.
Ross, J. M.: Post-mortem Appearances. Fourth edition., 1939.
Ruhman, W.: Rheuma und Hautreiz. 1937.
Ruhman; W.: Drastische Hautreizbehandlung. 1938.
Trowell, H. C.: Diagnosis and Treatment of Diseases in the Tropics. 1939.
Turner, C. E.: Personal and Community Health. Fifth edition. 1939.
Walker, N., and Percival, G. H.: Introduction to Dermatology. Tenth edition. 1939.
Weissenbach, R. J., and Françon, F.: Les Rheumatismes, Maladies Sociales. 1939.
Wohlfeil, T.: Die Diphtherieseuchenwelle in Deutschland und ihre Bekämpfung mittels der aktiven Schutzimpfung. 1939.
Zinsser, H., and Bayne-Jones, S.: Textbook of Bacteriology. Eighth edition. 1939.

Assurance for Doctors

The Medical Insurance Agency will endeavour to advise members as to changes in assurance conditions arising out of the war and other related topics of interest to the profession. Such advice will be tendered, as hitherto, in brief communications which will continue to appear in this *Supplement*.

Naval, Military, and Air Force Appointments

ROYAL NAVAL MEDICAL SERVICE

Surgeon Lieutenant Commander M. A. Graham-Yooll to be Surgeon Commander.

ROYAL NAVAL VOLUNTEER RESERVE

To be Surgeon Lieutenant Commanders: R. S. Thomas, J. M. McEwan, D. M. Reid, and S. B. White.

Surgeon Lieutenant R. G Reid to be Surgeon Lieutenant Commander.

Probationary Surgeon Lieutenants A. D. Petro, G. L. Ward, C. E. B. Rickards. H. Miller, F. G. Ward, R. W. Smith, T. T. Hardy, J. N. Cave, C. S. Cave, H. K. Childs, and R. L. Thompson to be Surgeon Lieutenants.

Lieutenant Commander T. G. Willis, R.N. (ret.), to be temporary Surgeon Lieutenant.

A. H. D. O. Richmond, L. D Arden, A. B. R. Finn, D. H. T. Duggan, C. H. Terry, W. W. Wildman, and S. J. H Miller to be temporary Surgeon Lieutenants.

ROYAL AIR FORCE MEDICAL SERVICE

The following have been granted short service commissions as Flying Officers for three years on the active list as from September 4, 1939, and with the seniorities indicated in parentheses: A. R. Agate, J. L. Brown, L. W. Davies, M. McLellan, F. T. Moore, R. Napier, W. R. Parker, J. W. Reade, and A. Wardale (September 4, 1938), R. Maycock (March 13, 1939), B. C. Curwood, C. Huddlestone J. A. MacCarthy, and A. McDougall (September 4, 1939).

ROYAL AIR FORCE RESERVE: MEDICAL BRANCH

J. J. Conybeare, M.C., has been granted a commission for the duration of hostilities as Group Captain

Postgraduate News

The times of the lectures to be given at the London Homoeopathic Hospital (Great Ormond Street, W.C.) have been altered as follows: Honyman Gillespie Lectures by Dr. C. E. Wheeler on Mondays and Thursdays at 2 p.m., beginning on October 16; Compton Burnett Lectures by Sir John Weir on Fridays at 2 p.m., beginning October 13; Tutorial Class on Fridays at 3 p.m., beginning October 13; Clinical Tutorials on Mondays and Fridays at 11 a.m.; introductory lecture to this course, October 12, at 2.30 p.m.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

Section of Therapeutics and Pharmacology.—Tues., 2.30 p.m. Presidential Address by Sir William Willcox: Pharmacy and Pharmacology.

Medical Society of London, 11, Chandos Street, W.—*Mon.*, 5.15 p.m., Annual General Meeting. 5.30 p.m., Presidential Address by Mr. V. Zachary Cope: The Profession of Surgery.

VACANCIES

Examining Factory Surgeon.—The appointment at Manningtree (Essex) is vacant. Applications to the Chief Inspector of Factories, Home Office, Whitehall, S.W.1, by October 17.

Medical Referee under the Workmen's Compensation Act, 1925, for the County Court Districts of Bradford, Keighley, Otley, and Skipton (Circuit No. 12). Applications to the Private Secretary, Home Office, Whitehall, S.W.1, by October 23.

APPOINTMENTS

Blackman, H. G. B., M.R.C.S., L.R.C.P., Examining Factory Surgeon for the Wiveliscombe District (Somerset).

Ritchie, T. F., D.S.O., M.B., Ch.B., Lieutenant-Colonel, R.A.M.C. (ret.), Assistant Medical Officer (Civil Defence—Medical Service), Birkenhead.

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this heading is 9s. This amount should be forwarded with the notice, authenticated by the name and address of the sender, and should reach the Advertisement Manager not later than the first post Tuesday morning to ensure insertion in the current issue.

DEATH

Comrie.—At 25, Manor Place, Edinburgh, on October 2, 1939, after a few months' illness, John Dixon Comrie, M.A., B Sc., M.D., Vice-President, Royal College of Physicians, Edinburgh, Lecturer on the History of Medicine at the University of Edinburgh in his sixty-fifth year; son of the late Dr. John Dixon Comrie, Peterhead.

WAR NOTICES

First-aid Posts

1. It will be recalled that in April of this year it was agreed between the Ministry and the British Medical Association that practitioners designated to be in general charge of personnel at first-aid posts should be remunerated at 20 guineas a year. It was understood that in return for this fee the practitioner would attend at least once a month for the purpose of supervising the collective training of personnel assigned to the first-aid post.

2. At the outbreak of war an entirely new situation arose, particularly in the London area. Many medical practitioners attached to first-aid posts assumed heavy responsibility in organizing those posts and in training personnel who were in the main inadequately trained. In some areas this meant practically whole-time work in the early weeks of the war. The Association raised this issue with the Ministry of Health, pointing out that the rate of payment which had been agreed between the Association and the Ministry was regarded as a peace-time arrangement, and that it was obvious that a fee of 20 guineas per annum for the work undertaken in the early part of the war was entirely inadequate. The sessional fee, on the other hand, was regarded as adequate for attendance during an air raid or attendance at the first-aid post from the moment the warning is sounded. The Association also raised the general question of the future remuneration of practitioners attached to first-aid posts for the continuous day-to-day supervision that would be needed to maintain standards of efficiency and co-operation.

3. In reply to these representations the Ministry of Health indicated on September 21 that it recognized that where some personnel are being employed whole-time at first-aid posts, some intensive training must devolve on the doctors for a period after the outbreak of war, and that it was reasonable that such doctors should receive additional remuneration to cover the extra work of bringing the personnel up to war-time efficiency. The Ministry suggested an increase in the fee for collective training of 10 guineas for six months to doctors in the first-aid posts in question. This fee would be payable only where the doctor was attached to a post at which whole-time personnel had been authorized and were employed, and where the medical officer of health considered that the attendance by the doctor at his post, over and above what he had been doing in peace-time, was necessary in order to bring the personnel up to a proper standard of efficiency.

4. On September 22 the Association informed the Ministry that it regarded these proposals as quite unsatisfactory. It was suggested to the Ministry that it had not appreciated the magnitude of the problem and the nature and extent of the intensive work which had been carried out on the instructions of medical officers of health by practitioners attached to first-aid posts. It was suggested to the Ministry that there should be convened a meeting of representative practitioners attached to first-aid posts and representative medical officers of health.

5. In reply the Minister agreed to receive a deputation of representative practitioners and medical officers of health for a discussion of the whole situation. This meeting took place on October 5, and the opportunity was taken to urge upon the Minister an immediate revision of policy on this subject. The reply of the Minister is now awaited.

Petrol Rationing

6. As a result of the strong pressure which the Association has brought to bear on the Petroleum Department, the Divisional Petroleum Officers have been authorized to issue to medical practitioners, without reference to the Department in London, a second supplementary ration up to a maximum representing a very substantial increase in the total allowance which they have hitherto been permitted to give on their own responsibility. Appeals from medical practitioners who require more than the maximum second supplementary ration will be considered as early as possible, but for the time being these cases must be referred to London in order that the staff of the Petroleum Department may take the measure of the problem. The Association will continue to do everything possible to ensure that the legitimate claims of medical practitioners are dealt with reasonably and expeditiously.

The Unaccompanied Children Pool

7. The difficulty of devising appropriate financial machinery for paying the Unaccompanied Children Pools in reception areas has been increased by the movements of those sent into these areas since the original evacuation. In some cases further evacuation has taken place, and in many instances persons evacuated have returned to their homes.

8. It has been provisionally agreed with the Ministry that a payment on account should be made to all local Pools in November or early December. This amount will be in respect of the four-months period ended December 31, and will be distributed by Local Emergency Committees within a few days of that date. It is an interim payment, and a further payment in respect of the same four-months period will be made early in the New Year when the fuller figures are available. The actual formula to be employed in arriving at the final estimate is now the subject of negotiation.

9. From January 1, 1940, payments will be made quarterly, but the administrative details must necessarily be decided in the light of the circumstances obtaining next year.

House-men and the Emergency Medical Service

10. A large number of house officers enrolled in the Emergency Medical Service have, within the past few days, received a letter from the Ministry of Health cancelling their appointments on the grounds that "it was not appreciated that they were under contract to a hospital." The Association immediately raised this matter with the Ministry of Health, which has now decided to pay for three months the salary to all house officers recruited in class A (g) of the Service—that is, at the rate of £350 per annum.

P25498

11. The terms and conditions of service and the methods of recruitment of house officers are under review and will be the subject of an early announcement. In this review the various anomalies to which attention has been drawn will be rectified.

Women Practitioners in the Army Medical Services

12. It was reported in these War Notices in the *Supplement* of September 30 that the Army had authorized a scheme for the employment of women practitioners with the Army Medical Services. The first request received by the Central Emergency Committee from the War Office for ten women practitioners under 40 has been met and the appropriate recommendations made to the War Office.

13. It is not yet known when further requests will be received for women practitioners for service with the Army or with other Services, or what the size or nature of any future request may be. There is, however, being maintained at this office a reserve list of women practitioners who desire to volunteer for such Services, and any practitioner who desires that her name should be added to the list should report this fact to the Secretary of the Local Emergency Committee in her area.

Transfer of Public Health Practitioners

14. There will be found in this *Supplement* a summary of Circular 1882 issued by the Ministry of Health. In this circular local authorities in reception areas are advised to adopt one of two methods in obtaining any additional public health personnel they need. They may arrange directly with the local authority of the evacuation area from which their additional population has been received to transfer a medical officer, the responsibility for paying such a transferred officer remaining with the evacuation authority. On the other hand, a local authority in a reception area may, through its medical officer of health, report its need to the Local Emergency Committee, which will request the Central Emergency Committee to make available to the reception authority a practitioner or practitioners from the reserve list maintained at this office. If this method is adopted the local authority of the reception area will appoint and remunerate the transferred practitioner, recovering the cost as an evacuation charge from the Government.

CENTRAL EMERGENCY COMMITTEE
(Central Medical War Committee),
British Medical Association House,
Tavistock Square, W.C.1.

BILLETING OF DOCTORS

It has been found, states an amending circular (Circular 1883) from the Ministry of Health to local authorities on the billeting of extra doctors and hospital staffs, that as a rule it is more convenient for such staff to take their main meals, if not all of them, in the hospital. Where this is so the hospital staff should be billeted on the "accommodation" instead of on the "board and lodging" basis, and the householder paid 5s. a week for each person instead of 21s. It is again emphasized, as in the earlier circulars on this subject issued on August 24 last, that the streets and houses selected for billeting hospital staff should be within one mile of the institution to be served, and should be as quiet as possible, as some of the staff have to sleep in the day time. Medical officers who are enrolled in the Emergency Medical Service are paid direct by the Ministry, with an allowance for board and lodging if these are not provided. If the doctor is billeted 21s. will be withheld from his allowance, but the difference between 21s. and that allowance will be paid to him in consideration of meals which must be taken out and of transport between the billet and the hospital. If he arranges to have a meal in the hospital he should be charged an appropriate messing fee, and no cost should fall on the hospital. Medical students who are assisting in the Emergency Hospital Service but are being paid no salary should be provided with board and lodging, where that is necessary, without charge, and the costs included in the running costs of the hospital, in respect of which a claim may be made on the Ministry.

EMERGENCY HOSPITAL SCHEME

GROUP OFFICERS AND HOSPITAL OFFICERS

The Ministry of Health and the Welsh Board of Health have supplied the following up-to-date lists of those medical practitioners who have been appointed Group Officers and Regional Hospital Officers. Those Group Officers whose names are marked with an asterisk are employed on a part-time basis; the remainder are on a whole-time basis.

GROUP OFFICERS FOR LONDON

Sectors I and II.—Russell Howard, C.B.E., F.R.C.S., Essex County Hospital, Hermon Hill, Wanstead.
Sector III.—Sir Girling Ball, F.R.C.S., Science Block, Mill Hill School, Mill Hill, Middlesex.
Sector IV.—W. J. Pearson, D.S.O., M.C., M.D., F.R.C.P., Brockley Hill House, Brockley Hill, Stanmore.
Sector V.—H. E. A. Boldero, M.D., F.R.C.P., Charlbury, Chorley Wood Road, Rickmansworth.
Sector VI.—Sir Charles Wilson, M.C., M.D., F.R.C.P., Cave House, High Street, Uxbridge.
Sector VII.—C. H. S. Frankeau, C.B.E., D.S.O., F.R.C.S., Percy House, P.A.I., Twickenham Road, Isleworth (Middlesex C.C.).
Sector VIII.—C. Max Page, D.S.O., F.R.C.S., Surrey County Hall, Kingston-upon-Thames (Surrey C.C.).
Sector IX.—John Hunter, M.C., F.R.C.S., "Sherwood," adjoining Horton Mental Hospital, Epsom (L.C.C.).
Sector X.—Professor T. B. Johnston, M.D., Boundary House, Orpington P.A.I. (Kent C.C.).

GROUP OFFICERS FOR PROVINCES

Birmingham.—L. G. Parsons, M.D., F.R.C.P., Public Health Department, The Council House, Birmingham 3.
Liverpool.—K. W. Monsarrat, F.R.C.S.Ed., The Medical Institution, Liverpool 3.
Manchester.—A. H. Burgess, F.R.C.S., 17, St. John Street, Manchester 3.
Sheffield.—A. G. Yates, M.D., F.R.C.P., 53, Wilkinson Street, Sheffield 10.
Leeds.—Harold Collinson, C.B., C.M.G., D.S.O., F.R.C.S., 27, Park Square, Leeds 1.
Bristol.—Professor Hey Groves, M.D., F.R.C.S., 25, Victoria Square, Clifton, Bristol.
Newcastle.—F. C. Pybus, F.R.C.S., Windsor House, Jesmond Road, Newcastle-upon-Tyne 2.
Hull.—*T. Ritchie Rodger, M.D., F.R.C.S., J.P., 21, Albion Street, Hull.
Bradford.—J. F. Allan, M.B., Ch.B.Ed., Bridge End, Low Baildon, Shipley, Yorks.
Stoke-on-Trent.—*E. C. Myott, M.D., B.S., 10, Brook Street, Stoke-on-Trent.
Brighton.—L. A. Parry, M.D., F.R.C.S., 5, The Drive, Hove, Sussex.
Walsall.—*Robert Forrest, M.B., Ch.B., "Halmot," Broadway, Walsall.
Reading.—*G. O. Lambert, M.D., M.R.C.P., 9, Eldon Square, Reading, Berks.
Oxford.—*Major-Gen. Sir Robert McCarrison, C.I.E., M.D., F.R.C.P., 41, St. Giles', Oxford.
Exeter.—*Col. R. Pickard, C.B., C.M.G., M.D., F.R.C.S., 1, Barnfield Crescent, Exeter.
Nottingham.—*W. T. Rowe, M.C., M.D., F.R.C.P., 8, The Ropewalk, Nottingham.
Leicester.—*John P. W. Jamie, M.C., M.D., Public Health Department, 17, Friar Lane, Leicester.
Coventry and Warwick.—*G. G. Alderson, M.B., B.Ch., F.R.C.S., Offchurch, Leamington.
Derby.—*F. G. Lescher, M.C., M.D., M.R.C.P., 307, Burton Road, Derby.
Sunderland.—*Paige C. Arnold, M.D., B.S., 13, Grange Terrace, Sunderland.
Cambridge.—Professor J. A. Ryle, M.D., F.R.C.P., Regius Professor of Physic, Department of Medicine, University of Cambridge.

WALES

Cardiff.—*R. Armstrong, M.B., Ch.B., Cardiff Royal Infirmary, Newport Road, Cardiff.

REGIONAL HOSPITAL OFFICERS

No. 1 Northern Region.—Col. H. T. Bates, O.B.E., M.B., Ch.B., Clarendon House, Clayton Street West, Newcastle-upon-Tyne.
No. 2 North Eastern Region.—C. F. Good, M.R.C.S., 8, The Headrow, Leeds.
No. 3 North Midland Region.—G. C. Kelly, M.D., 28A, Regent Street, Nottingham.
No. 4 Eastern Region.—A. L. Banks, M.D., University of Cambridge, Tennis Court Road, Cambridge.
No. 5 London Region.—J. Nairn Dobbie, M.B., 21, Cromwell Road, S.W. 7.
Deputy: Wing-Commander Brown.

No. *6 Southern Region.*—A. L. Dykes, M.D., 17, Bath Road, Reading.
No. *7 South-Western Region.*—C. R. Nicholson, M.R.C.S., 3, Woodland Road, Tyndall's Park, Bristol.
No. *8 Wales Region.*—A. Trevor Jones, M.D., Welsh Board of Health, Cathays Park, Cardiff.
Deputy: H. Collin Davies, M.D.
No. *9 Midland Region.*—Col. A. B. Ward, C.B.E., D.S.O., M.B., 139, Hagley Road, Edgbaston, Birmingham 16.
Deputy: A. E. Tudor Hart, M.R.C.S.
No. *10 North-Western Region.*—W. H. C. Patrick, M.D., Sunlight House, Quay Street, Manchester.
Deputy: Lieutenant-Colonel Dunn.
No. *12 South-Eastern Region.*—W. S. M. Craig, M.D., The Chestnuts, Grove Hill Road, Tunbridge Wells.

PUBLIC HEALTH SERVICES IN RECEPTION AREAS

A comprehensive statement (Circular 1882) on public health services in reception areas has been sent by the Ministry of Health to county councils and local receiving and evacuation authorities, including the metropolitan boroughs. The subject is considered under nine headings: personnel, medical arrangements for school children, medical treatment for mothers and young children, maternity and child welfare services, arrangements for expectant mothers and young children, additional hospital accommodation for infectious diseases, provision of "sick bay" accommodation for minor illness, emergency hospital scheme, and difficult children. An appendix deals with day or residential nurseries.

In the opening paragraphs attention is drawn to the need for continued co-operation and collaboration between the authorities of evacuation areas and reception areas, and for the former to continue to give every assistance to the latter in providing health services for their increased populations. Evacuation, it is pointed out, does not mean that evacuation authorities are to be relieved of all existing burdens for their transferred populations because services are being provided elsewhere.

Personnel

On being informed of receiving authorities' needs evacuation authorities should release such staff—medical officers, school dentists, nurses, midwives, health visitors, and staffs of fever and other hospitals—as may be practicable, at least as a temporary measure. The staff will remain in the service of the evacuation authority, who can seek advice from the Ministry's Regional Medical Officers on the co-ordination of demands from different receiving authorities. Where no arrangement has been made for the evacuation authority to continue to pay the salaries of the staff supplied the receiving authority should make such payment in the first instance as a charge to be reimbursed by the Ministry and allocated finally between the Exchequer and the evacuation authority.

As regards medical staff, receiving authorities should, where no direct arrangement has been made with evacuation authorities, make known their requirements to the Secretary of the Central Medical War Committee, British Medical Association House, Tavistock Square, London, W.C.1, and evacuation authorities should supply the Committee with the names of those medical officers whom they would be prepared to release temporarily. Under this procedure receiving authorities would pay the salaries, subject to reimbursement as above.

It is suggested that nursing staffs of casualty hospitals might, after consultation with the Hospital Officer for the region and the hospitals concerned, undertake work among the evacuated population until it may prove necessary to recall them. The hospitals will continue to pay nurses transferred in this way, the cost being included in the claim for the expenses of providing the casualty service.

Any proposals by receiving authorities for the employment of additional staff for the extended health services will require the Minister's approval, and should be submitted in the first instance to the Ministry's Regional Medical Officers.

Medical Attention for School Children

Attention is drawn to the need for extending the school medical service to the increased school population, and here again authorities in evacuation areas are asked to release for this purpose any of their school medical officers who can be spared. School nurses should not be diverted to other duties if there is need of their services in the reception areas.

Arrangements have been made in co-operation with the Central Medical War Committee of the British Medical Association for the domiciliary treatment by general practitioners of unaccompanied school children. There will be no charge to the householder, and the practitioner will be paid by the Local Medical War Committee, not the local authority. Mothers with young children under school age who are able to pay for the attendance of a local doctor should do so. If they have not sufficient means the district medical officer should be called in.

Maternity and Child Welfare Services

Arrangements should be made to extend to mothers and children under 5 who have been evacuated the existing welfare facilities, including health visiting, infant welfare centres, ante- and post-natal work, dental treatment, and cheap milk or meals for expectant and nursing mothers and young children. Special emphasis is laid on the arrangements for the supply of milk and meals to expectant and nursing mothers and children under school age being available to the evacuated population equally with the ordinary population of the area. Evacuation authorities should help by releasing personnel and by lending equipment where necessary and practicable.

In some areas difficulty has been experienced in providing accommodation for women before admission to or discharge from an emergency maternity home. It is suggested that local authorities should consider establishing mothers' hostels within easy reach of the maternity homes, the mothers either boarding themselves or contributing to the cost. Mothers whose confinement can take place in billets should, if they can afford to do so, arrange with the householder for their maintenance during confinement. An expectant mother who is not entitled to maternity benefit and is unable from her own resources to arrange for her maintenance will be eligible for an allowance from the local office of the Ministry of Labour. Where confinement takes place in a maternity home or hospital the cost or such proportion of the cost as the woman's means allow should be recovered by the welfare authority.

Infectious Diseases

The need for additional accommodation for the treatment of infectious diseases, notifiable and otherwise, should, the circular states, be regarded as urgent, and in general could best be met by the adaptation and equipment of empty houses. Proposals for this purpose should be submitted in the first instance to the Ministry's Regional Medical Officers. Recourse may be had, where satisfactory arrangements cannot be made, to the requisitioning powers delegated by the Minister to the clerks of local authorities. Some redistribution of the trained nursing staff between existing institutions and the new emergency accommodation and some additional staff from the Civil Nursing Reserve may be necessary. Evacuation authorities should also assist by releasing nurses with experience of work in fever hospitals. Arrangements are being made for the central purchase of furniture and equipment for this additional accommodation. Medical officers of health should make their needs known to the county medical officer for transmission to the Ministry.

"Sick Bay" Accommodation for Minor Ailments

The Minister is prepared, providing his Regional Medical Officer is satisfied of the need, to authorize the provision of accommodation in separate houses for children suffering from minor illnesses or convalescent from more serious illnesses who cannot properly be cared for in their billets. The establishment of these "sick bays" requires careful medical control; cases should be admitted only on the recommendation of a medical practitioner, the practitioner should continue to attend regularly at the "sick bay," and the staff should include at least one trained nurse.

Emergency Hospitals Scheme

Reference is made to an earlier communication from the Chief Medical Officer of the Ministry to medical officers of health, which stated that while there must not be any conflict with the discharge by the casualty hospitals of their proper functions, the extent to which any accommodation could be available for other purposes would necessarily depend on the number and nature of casualties. It was not intended that any provision not immediately required for casualties should be left unused while cases of serious illness were unprovided for. The Government is prepared to pay receiving hospitals for the cost of providing in-patient treatment for children who have been evacuated unaccompanied by an adult on the same basis as for casualties.

Difficult Children

Institutional accommodation—using empty houses or other suitable premises, with a staff experienced in child guidance—is desirable for those evacuated children in whom difficulties of behaviour make them unacceptable in ordinary billets. A register of persons experienced in child guidance work and a clearing house for information on cases to which medical officers and social workers can apply is being prepared by the Mental Health Emergency Department, 24, Buckingham Palace Road, London, S.W.1. If the local education authority of the evacuation area agrees, these "difficult" children may, if necessary, be sent to suitable special schools which are able to admit such cases.

Day or Residential Nurseries

In many cases it may be necessary to provide short-stay nurseries for young children during the lying-in period of the mother or when she is ill. The home should not have more than twenty-five children and preferably fewer, and should be in the charge of a matron who is a State-registered nurse. Long-term residential nurseries will also be necessary for children separated from their mothers for longer periods. Infants under 9 months should not ordinarily be admitted, and the number of resident children should not exceed thirty-five, preferably fewer. Detailed advice is given in the circular on the size, equipment, and management of these nurseries.

Provision should be made, it states, for the medical supervision of all children on admission to the nursery and for their examination when necessary. The medical officer, who should act under the general direction of the medical officer of health, should visit the nursery at frequent intervals and be available at other times in case of emergency, and should be generally responsible for arrangements for the feeding and health of the children.

B.M.A. SCHOLARSHIPS

At a meeting of the Science Committee of the British Medical Association the reports of the Association's Visitors on the work of the Scholars for the year 1938–9 were received.

Ganglionic Sympathectomy in Achalasia of the Cardia

Dr. G. C. KNIGHT (Ernest Hart Scholar) has been contrasting the effects of pre- and post-ganglionic sympathetic section for the relief of artificially produced achalasia of the cardia. Previous experiments in 1933–4 had shown that the cardiac sphincter received a sympathetic nerve supply. Excision of both lateral sympathetic chains in the cat produced a patulous sphincter with increased peristalsis of the oesophagus. Stimulation of sympathetic nerve fibres accompanying the left gastric artery caused contraction of the sphincter, and denervation of these fibres again resulted in a patulous sphincter, demonstrating that part at least of the fibres from the lateral chains took a recurrent course from the cardiac plexus to reach the cardiac sphincter. Encouraging results followed the application of these findings to the treatment of experimental achalasia of the cardia resulting from bilateral vagal section, for it was shown that either lateral chain sympathectomy or coeliac sympathectomy relieved the obstruction at the cardiac sphincter. Coeliac sympathectomy was applied to the treatment of cardiospasm in man with conflicting results. In many cases the operation had no permanent effect, although immediate post-operative improvement was observed for periods up to six months (as indeed occurs after any treatment in some of these patients), and yet successes have been noted by Adamson, Telford, Learmonth, and McConnell. Coeliac sympathectomy alone may be an incomplete operation, and, since it is in any case a post-ganglionic section, some form of pre-ganglionic operation might produce better results by avoiding adrenaline sensitization if this occurs in the alimentary tract. The present investigation was directed to elucidate these points: (A) By contrasting the effect upon the cardiac sphincter studied by x rays at one, three, and six months' intervals of certain surgical procedures, the results showing that whereas bilateral vagotomy produced a picture of achalasia, in one case recovery occurred spontaneously after five months of partial obstruction, and that the immediate effect of complete bilateral thoracic sympathectomy remained for three months subsequently, but then disappeared, the sphincter regaining its tonus. It seemed that the sympathetic supply to the lower part of the oesophagus came mainly from below the level of the fifth thoracic ganglion; the effect of pre-ganglionic sympathectomy upon the cardiac sphincter was less striking than that of total sympathectomy, but five months after the operation there was still increased peristalsis and a more rapid passage through the sphincter, whereas in total sympathectomy the effect was already weakened. (B) By fourteen acute experiments to try whether an accurate localization of the site of outflow to the cardiac sphincter could be obtained by stimulation of the lateral thoracic chains, and whether any evidence of adrenaline sensitization could be detected in animals previously treated by bilateral thoracic sympathectomy or pre-ganglionic sympathectomy. The conclusions were that the effect of bilateral vagotomy was not necessarily permanent; that pre-ganglionic section appeared to have a more permanent effect upon the oesophagus than complete sympathectomy; and that there was no evidence of a sympathetic supply to the lower oesophagus in the cat leaving the lateral chain above the level of thoracic V. This last point was in accordance with the recent findings of Mitchell, and it might be advisable later on to study the effect upon the human cardia of paravertebral novocain injections of the lower thoracic ganglia. A series of experiments to determine the effects of stimulation at different levels in the hypothalamus on respiration showed that stimulation of the anterior hypothalamus might produce apneustic respiration, complete inhibition, or decrease in rate with increase in depth. Stimulation of the posterior hypothalamus might give rise to acceleration of respiration with decrease in depth. After the administration of curare a rise of endotracheal pressure occurred, evidencing an increased resistance of the lung to distension (1) during actual stimulation of the hypothalamus; (2) as a prolonged and gradual rise following stimulation; (3) in certain cases a transient rise occurred immediately after the injection of curare; and (4) a rise of endotracheal pressure immediately before death due to congestion of the lungs. No such rises were noted in the control animals. The increased resistance was most probably located in the bronchial musculature, and brain sections are being investigated to determine the site of the brain lesions.

The Association's Visitor, Professor F. R. Fraser, remarked that this scholar had made good use of his time and opportunities; he had cleared up some of the problems he had set out to solve; and, even if it was disappointing that his work did not indicate how sympathectomy might be utilized in the treatment of cardiospasm, he had made a real contribution to knowledge. His work on the effect of stimulation of the hypothalamus was an endeavour to throw light on the occurrence of respiratory failure following operations in this area. The work was done in the laboratories of the Royal College of Surgeons.

C.S.F Pressure in Health and Disease

Dr. A. M. Barry (Walter Dixon Memorial Scholarship) has been investigating in the laboratories of the National Hospital, Queen Square, the cerebrospinal fluid pressure and volume in both health and disease, with special references to the connexion between raised C.S.F. pressure and papilloedema, focusing attention upon cerebral tumour, hydrocephalus, and arterial hypertension. Professor Fraser states that Dr. Barry found it first necessary to determine the compressibility of brain tissue and had devised an apparatus for this purpose. He had found that the compressibility of brain tissue was approximately the same as that of water. This work had been carefully and critically performed, and would probably form part of a report on studies on intracranial pressure by Dr. Carmichael when the work had been completed. Following this, he had taken part with Dr. Carmichael in investigations of vasomotor reflexes from the rectum and duodenum and involving estimation of the velocity of impulses in the involuntary nervous system. This work involved the devising of complicated apparatus to give quantitative estimations of very small differences in time. Forming a part of larger problems which are being investigated in the department, the complete report will be published in due course by Dr. Carmichael.

Gastroscopy in Diagnosis

Dr. H. Taylor (Ordinary Research Scholarship, renewed) has been working in the wards and operating theatres of the London Hospital. As regards the general availability of gastroscopy when indicated in gastric cases he reported 282 successful results out of 300 attempts. Out of 350 cases of definite established carcinoma of the stomach 10 per cent. had been diagnosed by gastroscopy before the operation. In seven instances two or more examinations were necessary, a new approach to the early diagnosis of carcinoma being thus made—namely, by observing the changes in the appearance of the lesion in early cases with the lapse of time. The prognosis in these early cases is better than in the general group of carcinomas of the stomach, so that this test for malignancy might be expected to improve the proportion of successful operations. In these seven cases carcinoma would not have been diagnosed without gastroscopy; two were found to be inoperable, and in the remainder gastrectomy was successfully undertaken. A comparison was also made of the degree of hyperplasia, gastritis, and acidity. In a group of 89 cases, 39 had mucosal hyperplasia with gastritis but no ulcer in the stomach; 31 had hyperplasia and gastric ulceration; while 19 had gastric ulceration without hyperplasia. No certain relation was defined between the effect of gastritis on the acidity and in the various types of mucosal hyperplasia.

Professor Fraser remarks that his last finding suggests that test meals are of little value as an indication of the state of the mucosa in individual cases. The most important practical results of these researches in Professor Fraser's opinion relate to the diagnosis of carcinoma at stages in which *x*-ray examinations are not conclusive. Professor Fraser adds: "Dr. Taylor has accomplished a very satisfactory amount of work which is likely to lead to earlier diagnosis of gastric carcinoma. The value of his observations on hypertrophic states of the mucosa in relation to peptic ulceration cannot yet be evaluated, but they should form a valuable basis for further investigations. His work will form the subject of a Hunterian Lecture to the Royal College of Surgeons."

Vascularity in Relation to Radiosensitivity of Neoplasms

Dr. J. B. Gaylor (Ordinary Research Scholar) has been studying in the Gardiner Institute of Medicine the problem of assessing the vascularity of neoplasms by physical means. As a first approach the vascularity of the skin was studied as being the tissue most easily observed experimentally. The index of blood flow provided by temperature readings as measured by thermal junctions was studied during full constriction up to full dilatation of the vessels. The gradient of rise of temperature produced by a constant stimulus of heating indifferent limbs was observed in a large number of normal and abnormal subjects. As a result of these observations the study yielded interesting incidental findings on the general subject of peripheral vascular disease. It is hoped to extend these observations and to correlate them with the results of plethysmographic experiments which will be made when further special recording apparatus has been installed. With this basis of experimental observations the data obtained will be applied to the study of the skin in sites of very different vascularity. The Association's Visitor, Professor J. W. McNee, has cordially approved the way in which the research is progressing in this and the following cases.

Muscular Hypotonia after Surgical Operations

Dr. J. D. Olav Kerr (Ordinary Research Scholar) has been working also in the Gardiner Institute of Medicine, where animal experiments on muscular tonus proved promising, as reported in these columns last year (*Supplement*, 1938, 2, 191). He states that during the current year muscular hypertonia has been studied in man following surgical operations and in acute medical illnesses. The influence of certain anaesthetics on muscular tonus was noted, and observations were conducted on the effect of strychnine in combating hypotonia. The collection of a sufficient number of cases to justify conclusions being drawn is taking longer than was expected, and no paper has yet been presented for publication.

Professor J. W. McNee, endorsing this statement, announces also that it is proposed by Dr. Olav Kerr that this investigation, when completed, shall be followed by experimental work in connexion with a study of the comparative anatomy of the heart, with special reference to the coronary vessels and conducting system.

Bacteriology of Skin Diseases

Dr. Beatrice Lewis (Ordinary Research Scholarship, renewed), continuing her work last year in the laboratories of the department of bacteriology at University College Hospital, has studied ninety-eight strains of *Staphylococcus pyogenes aureus* and nineteen strains of *albus*, obtained from skin lesions, systematically from the point of view of biochemical reactions, behaviour on gentian-violet agar, coagulase and haemolysin production, and reactions with various strains of staphylococcal bacteriophages. In more than ninety of these ninety-eight strains of *aureus* there was agreement between the results obtained by these methods in that mannite was fermented, the Vosges-Prokauer reaction was positive, a violet or deep orange-coloured growth was seen on gentian-violet agar, coagulase and haemolysin were produced, and the strains were sensitive to the five strong *Staphylococcus aureus* bacteriophages used, but were only slightly sensitive, or even unaffected, by the three weaker strains of bacteriophage employed. Work is proceeding on the preparation of rabbit sera against several of the strains in order to compare agglutination reactions with the previously mentioned results. Some further work has also been done on the serological typing of haemolytic streptococci obtained from skin lesions. It has been found possible to type only 22 per cent. of these strains so far, despite repeated attempts, modifications of the technique, including the use of Griffith's salts and also sera prepared from untyped strains. Professor Fraser remarks that this investigation has involved much laborious and time-consuming work since much repetition was necessary, and the bacteriophages obtained from Australia required to be passaged repeatedly, until a standard of activity was obtained, before they could be used for testing.

Correspondence

Petrol for Doctors

SIR,—In the *Supplement* of September 30 (p. 191) I note the statement that Divisional Petroleum Officers have been instructed to place medical practitioners in the highest category of priority in issuing supplementary petrol rations. If this is correct I hope we shall see a more generous allowance meted out to us for the second rationing period beginning on October 23 next.

In my own case, which I imagine is typical of that of other general practitioners, my total allowance of petrol for the thirty days September 23 to October 22, comprising (1) a completely full tank (unrationed) at the start, (2) the basic ration, and (3) the supplementary ration, will enable me to do an average daily distance of twenty-two and a half miles, in spite of the fact that I stated that my average daily mileage during the last year was practically thirty-nine for all purposes—the actual figure is 1,161 miles per month.

I think it is a fair assumption that by using the car solely for professional purposes the mileage will be immediately cut down by a quarter. This would put my average at thirty miles daily on professional work alone. My practice is in a neutral area, and although a large number of people have gone away it seems that numbers are already returning, so that I do not anticipate a really large falling off in the amount of work to be done in the winter, although this is certain to be less than the average. This area is an urban district of considerable size, and I have frequently done as much as forty-five to fifty miles a day during the winter months, using the car solely for professional purposes. If for the second rationing period beginning on October 23 I am allowed the same quantity of petrol, I shall only have enough to do an average daily distance of seventeen and a half miles, as in this case I shall not start the period with a full unrationed tank.

I am quite prepared to do visits near my home on either my feet or a bicycle, but it is impossible to do this if there is a large maternity bag or anaesthetic apparatus to carry, or in very bad weather. To expect one to cut down the mileage by over one-half appears to be altogether unreasonable, and if this happens it will be almost impossible to carry out even the contractual obligations to panel patients alone, apart from private practice. I sincerely hope that we shall not look in vain to the B.M.A. to press this matter very strongly. One hears from various—presumably reliable—sources that there is at present no prospect of any petrol shortage in this country, particularly with pleasure motoring now almost non-existent, and it might be a serious thing if the community were unable to obtain medical attention when required.—I am, etc.,

Coulsdon, Surrey, Oct. 1. R. B. P. LANSDOWN.

Remuneration and Grading in the Emergency Medical Service

SIR,—It is reported that in the House of Commons on September 13 the Minister of Health denied an allegation that dissatisfaction exists concerning methods of payment for the Emergency Medical Service. He seems to have overlooked the indisputable fact that certain people are to receive payment while others are not. For example, enrolment forms which were sent some time ago to various whole-time medical officers in voluntary hospitals have now been cancelled without explanation. In the case of my own radiological appointment no official recognition of any description has been received. It seems, therefore, that in common with other individuals in similar circumstances I am expected to deal with air raid casualties gratis. Lastly, certain radiologists enrolled for part-time hospital service are being offered terms applicable to general practitioners. Apparently the Ministry of Health is of the opinion that radiologists do not "rise to the dignity of specialists."—I am, etc.,

Wakefield, Sept. 28. JOHN A. G. F. ROSE.

*** The Ministry of Health has decided not to recruit to the Emergency Medical Service and so remunerate from Government sources practitioners holding whole-time voluntary hospital or local authority hospital appointments. On the second point, that of the grading of Class B officers, the Ministry has agreed to review the grading of these officers in the light of the observations of the Central Emergency Committee of the B.M.A. The lists are now being overhauled, and appropriate recommendations for regrading are being made to the Ministry of Health.—ED., *B.M.J.*

Certificates of Incapacity in War Time

SIR,—In every insurance practice there are a number of patients to whom the doctor is required to issue a certificate of incapacity once a month. In many such cases—elderly osteoarthritics and the like—this certificate is a pure formality, but in peace time the necessary visit to issue the certificate, whether undertaken by patient or doctor, is looked upon only as an irksome part of the day's work. In time of war, however, and particularly in country districts, it becomes a far more serious matter. The patient who should attend the surgery finds bus and train services enormously curtailed and the cost of local travel considerably increased. The doctor, on the other hand, has a limited supply of petrol, which he is asked not to waste.

In these circumstances could not the Ministry give insurance practitioners power to issue, say, quarterly certificates for those cases in which they are satisfied that more frequent attendances are only called for as occasion arises?—I am, etc.,

Perranporth, Oct. 2. DOUGLAS ROBB.

Postgraduate News

The Governing Body of the British Postgraduate School at Hammersmith has decided to carry on postgraduate instruction for the present.

A course of six lectures on the diagnosis and treatment of war neuroses (for general practitioners and others) will be given at the Tavistock Clinic (Westfield College, 8, Kidderpore Avenue, Hampstead, N.W.) on Monday, Wednesday, and Friday, October 16, 18, and 20, at 2.30 and 3.30 p.m. The fee for the course is 5s. (single lectures 1s.). Tickets are obtainable in advance from the educational secretary.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

General Meeting of Fellows.—*Tues.*, 2.30 p.m., removal from Roll and ballot for election to Fellowship.

Section of Radiology.—Fri., 2.30 p.m., discussion: Radiology in the War Emergency Services. Opener, Dr. A. E. Barclay, followed by Major D. B. McGrigor.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 26, Portland Place, W.—*Thurs.*, 4.30 p.m., Presidential Address by Sir Rickard Christophers, F.R.S.: Malaria in War.

BRITISH INSTITUTE OF RADIOLOGY, 32, Welbeck Street, W.—*Thurs.*, 4 p.m., Installation of President for 1939–40, etc.

MEDICAL SOCIETY OF INDIVIDUAL PSYCHOLOGY.—Owing to present circumstances there will be no meeting of the Society in October.

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this heading is 9s. This amount should be forwarded with the notice, authenticated by the name and address of the sender, and should reach the Advertisement Manager not later than the first post Tuesday morning to ensure insertion in the current issue.

DEATHS

SCORESBY-JACKSON.—On September 29, 1939, in Worthing, Margaret Scoresby-Jackson, M.D., elder daughter of the late R. E. Scoresby-Jackson, M.D., F.R.S.E., etc. The only intimation.

WHITESTONE.—Augustus Mayberry Whitestone (M.B., B.Ch., Trinity College, Dublin), at Beaufort House, Hollingbourne, Kent, on October 7, 1939, in his 83rd year.

WAR NOTICES

Unaccompanied Children

It was announced in this column on October 14 that initial payments into the Unaccompanied Children Pools in the reception areas, covering the four-months period ending December 31, would be of an interim character. Such payments will represent three-quarters of the sum provisionally estimated to be due in respect of the period in question. Payments thereafter will be quarterly, and will in effect be made up in each case of a final payment for the preceding quarter and an interim payment for the quarter just ended. These arrangements have been made necessary by the present uncertainty as to the probable number of evacuated children, due on the one hand to further evacuation movements in certain cases, while in many instances evacuees have returned to their homes in considerable numbers.

Protection of Practices

The time is arriving when closing dates will shortly be named in most areas, after which no further signatures to protection of practices schemes can be accepted. While these dates will vary locally, it is probable that in a large proportion of areas the closing date chosen will fall within the next month. Practitioners who have not yet signed the protection of practices scheme operating in their areas are asked to take this step without delay in the interests of absentee practitioners and themselves. Clerical work will be greatly simplified if this is done in advance of the official closing date.

Petrol Rationing

As has previously been announced in these columns, the Divisional Petroleum Officers have been authorized to grant a second supplementary ration to medical practitioners who require more than the original allowance, and to consider, in consultation with the Petroleum Department in London, applications from practitioners who need still further supplies. There have been some complaints of delay in dealing with applications, but it appears that much of this has been due to failure on the part of medical practitioners to apply on the official form or to send registration books with the forms. The importance of following the procedure laid down is again emphasized.

The British Medical Association is continuing its negotiations with the Petroleum Department with a view to ensuring that in future all legitimate claims of medical practitioners will be dealt with reasonably and with all possible speed.

Steel Helmets at First-aid Posts

Hitherto the issue of steel helmets to medical practitioners attached to first-aid posts has been confined to the medical officers in charge of posts. The view of the Central Emergency Committee was that it was of importance that helmets should be issued to all practitioners holding first-aid appointments, and some weeks ago representations to this effect were made to the Ministry of Health. The Committee has now been informed that the Ministry hopes that a sufficient supply of steel helmets will be available to make a general issue possible on the lines suggested.

Intention of Service

Practitioners who wish to modify their previous statement of their intention of service are being asked to communicate their revised offer in conformity with the following classification:

(*a*) Men under 50 years of age available for whole-time service at home and abroad with the defence forces.

(*b*) Practitioners available for whole-time medical work with the civilian population in any area.

(*c*) Practitioners wishing to continue with the medical work in which they are now engaged.

As previously announced, any such statements of change of intention of service should be addressed to the Central Emergency Committee.

Central Emergency Committee
(Central Medical War Committee),
British Medical Association House,
Tavistock Square, W.C.1.

WAR WOUNDS AND AIR RAID CASUALTIES

On April 15, 1939, there appeared in the *British Medical Journal* the first of a series of articles on the "Treatment of War Wounds and Air Raid Casualties." A considerable number of these articles had formed the basis of lectures delivered in March at the British Postgraduate Medical School; they were followed by supplementary articles contributed by invitation, and the series will be brought to a close in next week's *Journal*. In response to many requests from readers all the articles will be republished in book form by Messrs. H. K. Lewis and Co., with a foreword written by the Director-General, Army Medical Services. The volume, uniform in size and shape with vols. i, ii, and iii of *Treatment in General Practice*, is due for early publication at the price of 10s. 6d. net.

CASUALTY EVACUATION TRAINS

AMBULANCES ON RAILS

Thirty-four casualty evacuation trains have now been equipped and commissioned to assist, in the event of air raids, the distribution of injured from the first-aid or clearing stations to the base hospitals. Twenty of the trains are stationed on sidings in and around the Greater London area, and the remainder are in the provinces or in Scotland. They are under the direction of the Ministry of Health (in Scotland, the Scottish Board of Health).

Each train, which is a quarter of a mile in length, consists of nine goods vans, normally used for the carrying of fruit, milk, or other commodities, which have been converted into stretcher ambulances. A van will take thirty stretcher cases, making a total of 270 on the train, with provision for a few sitting cases. The windows of these extemporized wards have been blacked out, but special provision has been made for ventilation, and with a clear space down the middle of the train a through passage of air is obtained, particularly when the train is in motion. Screens are provided in each ward for preventing draught.

Every inch of the floor has been scraped and polished with cardinal red, giving a very cheerful appearance. One could not have imagined that any railway rolling stock could be as spotless as these trains have been made. The stretchers, of metallic netting and painted a pleasant green, are fixed against each wall in three tiers, and are provisioned with blankets and pillows. The wards are lighted by electricity, but are also fitted with hurricane lamps, and the heat is distributed by steam pipes carried along the top of the vans. At either end of each ward are two folding canvas chairs, and there is a folding table which can be put up in the middle for dressings.

The most careful anticipation has been made of what an emergency may demand in medical equipment and supplies. One compartment is fitted with cupboards containing dressings, all in such a form as to be available on the instant; and immediately to hand there are drugs, disinfectants, styptics, and various medical comforts such as brandy, meat extracts, malted milks, lime juice, and—the universal English stand-by in shock or upset—tea. Gowns, aprons, and towels are all in readiness. One tray is filled with specially made torches for use should an air raid take place while the train contains casualties.

At each end of the train there is a small kitchen with oil stoves for making light meals and hot drinks. One compartment is fitted with large hot and cold water tanks, another is a repository for bed-pans, buckets and pails, and the like. The same equipment is repeated at each end of the train, one end being for nurses and the other for orderlies. A compartment is assigned to the medical and train officers and another to the sisters, and there are other compartments where the nurses and orderlies can rest or change their clothes, and an ex-dining car is used as a lounge and dining room. The staff, when not on duty, are accommodated in billets near where the trains are berthed.

The crew of each train consists of one medical officer, one train officer, three sisters, two assistant nurses, six auxiliary nurses, and eight St. John Ambulance orderlies. The whole of the staff is on duty all day, and two of the orderlies remain on duty all night. The whole train—there are two trains on each siding—is off duty one day a week, and on Saturday afternoons and Sundays two orderlies are left in charge, the remainder of the staff being within call. Of course, should bad air raids start the staff are prepared for duty twenty-four hours a day. The train which our representative visited "somewhere in London" included among its orderlies the manager of a gas company and a civil servant, and among the nurses an artist's model, a mannequin, and a private secretary. Although so far the trains have not had to be in action for air raid casualties, the staff are ready for the instant call.

At a time when so much, not unjustified, public grumbling is taking place at the railway service, it is well to record that at the outset of the emergency the railway companies were asked to furnish these trains on the Friday night, and they were in readiness on the following Monday. One may hope that, notwithstanding the care and thought spent upon them and the pitch of perfection to which they have been brought, the necessity for their use will never arise; but we understand that they are liable to be commandeered by the Army or Navy should there be pressure on other ambulance transport. A number of ambulance trains for use at home and over-seas for the transport of naval and military sick and wounded have been completed by British railways, and others are in construction at seven workshops in different parts of the country. Each of these trains, like those allocated for casualty evacuation, is fully equipped with cars to serve the purpose of wards and kitchens, and for the use of travelling staffs of nurses and doctors.

Assurance for Doctors

Cars used for Civil Defence

On September 2 a statement was issued by insurers on the use of cars for civil defence work which made provision for four weeks from the declaration of war. Although the position has not been further defined the period covered by that statement has been extended to October 31. At the same time certain concessions have been made, and the position within the United Kingdom is now as follows:

> Voluntary use of motor vehicles for civil defence will be regarded as coming within the scope of current policies of all kinds up to and including October 31, 1939. The policy will be deemed to have been extended to cover the liability of the civil defence authority using the vehicle without being endorsed for this purpose. The driver in such circumstances may be any person permitted by the policy, which, in the case of the normal private-car policy, includes any licensed driver driving with the permission of the owner. Where passenger risk is already covered by the policy this cover will continue to operate. In other cases application should be made to the insurer.
>
> It should be pointed out that this extension of cover does not override any clause in the policy which excludes the consequences of war, etc. The policy, therefore, would not apply to claims arising out of specific acts of the enemy or of the defence services.
>
> This announcement applies also to vehicles requisitioned or otherwise taken over by civil defence authorities, the policies on which will continue to apply subject to the limitations referred to above, and will be extended without endorsement to indemnify the public authority. It does not apply to any vehicle taken over by acquisition or by his Majesty's Forces.

Sir Duncan Wilson, H.M. Chief Inspector of Factories, has sent a message to the National "Safety First" Association welcoming its decision to maintain its industrial accident prevention work during war time. "The adverse effect of industrial accidents on national efficiency is probably even more pronounced in war time than in peace. For war purposes the nation's ability to produce goods and a fighting force depends ultimately on the sum total of people who can be mobilized to work and fight. During war time there will be many new factors all tending to increase the chances of factory accidents. There is the dilution of skilled labour by unskilled. Even more potent is the invasion of industry by adult workers who are not only unskilled but are totally unused to factory conditions. There are longer hours of work and intensified production; there is probably a greater amount of monotonous work. In the early days there will also be a certain amount of disorganization and reorganization due to change over of personnel and plant to meet new conditions. All these things have an adverse effect on the accident problem. Perhaps the most serious because of its universal occurrence will be the influx of the inexperienced into industry. This may be aggravated by lack of time to give as much individual instruction as is desirable. The implication is obvious. The educational side of accident prevention will have to be considerably intensified and propaganda will have to be much more widespread if avoidable accidents are not to have a serious effect on national resources."

Correspondence

Private Practice for Members of the E.M.S.

SIR,—Recently there has been considerable discussion and "grousing" in medical circles about the ban on private practice by whole-time consultants belonging to the Emergency Medical Service. None of the remedies put forward have been received with much favour, chiefly because no one wishes to imitate the dog in Aesop's fables and drop the small bone they hold for the large shadow seen in the water. I would like to suggest a possible compromise—namely, to allow practice at other hospitals and in private within a radius of twenty-five miles. If it was thought that this distance was too far for a surgeon to wander in case of an air raid, then the distance could be less or even restricted to the central hospital itself. The Government should not forget that one guinea out of every three-guinea fee goes to the income tax.—I am, etc.,

Middlesex, Oct. 12, 1939. MALCOLM DONALDSON, F.R.C.S.

Medical Care of Evacuated Persons in Reading

SIR,—With reference to the paragraph in the *Supplement* of October 7 (p. 195) on the medical care of accompanied children you may like to note for the information of other areas that the Reading Public Assistance Committee has made arrangements with the Borough of Reading Medical Society, Ltd., which is the Public Medical Service for the area, for free choice of doctor for all public assistance cases where visits at the patients' houses are necessary. A small part of the borough is excluded, as this is covered by a district medical officer. Payment will be on an attendance basis of 5s. a visit, including medicine and certificate, if necessary; attendance at surgery 3s. 6d., including medicine and certificate if necessary; and where a report or certificate which is not of a simple character is required of the relieving officer, an extra payment of 2s. 6d. The arrangement is for the period of the war and subject to three months' notice on either side. Free choice of doctor is given and medicines will be dispensed by the P.M.S.—I am, etc.,

W. I. BAIN,

Oct. 12. Hon. Secretary, Reading Division of the B.M.A.

Swabs by Post in War Time

SIR,—Half an hour after swabbing a throat at 2 p.m. on Saturday afternoon I took the specimen to the post office and found the next collection to be at 7 p.m. Consequently it will be Tuesday afternoon before I receive a report from the laboratory. There appeared to be no other method of delivery other than a personal visit to the public health laboratory five miles each way, which my petrol allowance and my time do not permit. Many practitioners must be faced with this problem, especially since the rationing of petrol, and I feel sure that it could be possible for such urgent missions to receive the consideration of a Sunday delivery in the interests of the public health.—I am, etc.,

Gatley, Cheshire, Oct. 14. D. L. COOKE, L.R.C.P. and S.

Petrol Ration and the Late Message

SIR,—On my form No. R(MS) 1 I have entered the following as one of my reasons for needing extra petrol: "The publicity given to the absolute necessity for people to send for their doctor early in the day has been so feeble as to be entirely negligible in its effect, and frequently one or more afternoon and evening visits have to be made over ground already covered to see people who could perfectly well have sent at the proper time had they bothered themselves to do so. The genuine emergency does occur, but it is comparatively rare."

The late visit is a great trial to the doctor, and may, in no small measure, account for the fact that, according to the Registrar-General's returns, the longevity of the doctor compares unfavourably with that of other professional men. The Ministry of Health and the multitude of insurance committees are always very anxious to see that the people get all the benefits to which they are entitled. Great pains are taken, by means of newspaper articles and slips inside the medical card, etc., to let them know what their doctor must do for them. There is not nearly the same enthusiasm in educating the people as to what they should do for their doctor. There is never by any chance the slightest amplification of the fact that it is their duty, if circumstances permit, to send for the doctor before 10.30 a.m.

Perhaps it is not too much to hope that the steps taken to effect a drastic economy in the use of petrol may, at the same time, benefit the doctor by reducing the number of his unnecessary calls out of hours.—I am, etc.,

Birmingham, Oct. 15. J. RENWICK.

Naval, Military, and Air Force Appointments

ROYAL NAVAL MEDICAL SERVICE

Surgeon Lieutenant (Emergency) F. Bush to be Surgeon Lieutenant Commander (Emergency).

ROYAL NAVAL VOLUNTEER RESERVE

To be temporary Surgeon Lieutenant Commanders: L. W. Mortimer and J. B. K. Smith.

To be temporary Surgeon Lieutenants: D. C. S. Rendall, D. Heap, and D. W. C. Cox.

ROYAL ARMY MEDICAL CORPS

Lieutenant W. G. Macfie to be Captain, with seniority May 1, 1938. (Substituted for the notification in the *London Gazette* of May 5, 1939.)

The appointment of Lieutenant W. G. Macfie has been antedated to May 1, 1937, under the provisions of Article 36, Royal Warrant for Pay and Promotion, 1931, but not to carry pay and allowances prior to May 1, 1938.

Lieutenant (on probation) J. D. Condon has been restored to the establishment.

To be Lieutenants: D. Paton, C. B. Armitt, J. R. Beagley, C. R. Barker, E. R. S. Phillips, J. G. Reid, I. M. Sandilands, R. S. Adam, J. A. W. Miller, A. W. L. Smith, R. M. S. McConaghey, A. L. Frazer, K. P. Pauli, E. W. Pickard, N. Walsh, T. M. Boog-Scott, R. C. Jenkinson, P. A. Robinson, T. E. Anderson, A. Henderson-Begg, N. Nicholls, P. O'Higgins, H. G. Page, G. F. D. Perrott, P. B. Riley, H. M. Kelsey, W. H. Jones, H. D. Moore, M. L. Mundy, N. H. M. R. Monro, W. R. Owen, A. P. Procter, W. S. Rees, A. G. Smith, J. Woodrow, T. B. Field, P. O'Driscoll, J. W. Perrott, B. S. Alderson, M. W. Allen, W. S. Baxter, T. P. Bliss, F. J. Henderson-Begg, H. S. Calder, A. H. Dickie, J. G. De Vine, I. Ferguson, T. C. N. Gibbens, W. G. Graham, A. A. Grierson, G. A. S. Harris, C. M. Heath, T. McLardy, W. M. Owen, A. R. Reid, T. D. Ross, R. Woodrow, L. Herbert, J. W. Maycock, A. H. R. Champion, P. Noel-Hanson, N. A. Lawler, J. W. M. Leslie, P. C. F. Wingate, J. M. Brown.

ROYAL AIR FORCE MEDICAL SERVICE

The following Flying Officers to be Flight Lieutenants, with seniorities indicated in parentheses: L. L. Ingram (April 1, 1938), J. I. M. Smith (May 2, 1938), H. P. R. Smith (May 6, 1938), W. G. Holdsworth, J. L. Roche, J. F. MacCarthy, H. Ll. Jenkins, and P. A. O'Callaghan (September 5, 1938), W. A. T. Hill (March 5, 1939), C. W. Wollaston, and J. E. Dalton.

A. G. Burke has been granted a short service commission as Flying Officer for three years on the active list, as from September 4, 1939, and with seniority of September 4, 1938.

ROYAL AIR FORCE VOLUNTEER RESERVE: MEDICAL BRANCH

To be Squadron Leaders: J. C. Ainsworth-Davis and R. R. Trail.

To be Flight Lieutenants: G. Gray and D. J. Williams.

To be Flying Officers: R. J. Healy, D. D. Reid, J. A. Sinclair, and J. Sutcliffe.

R. T. Goodyear, D. E. Price, A. B. MacGregor, N. S. Taggart, D. A. P. Anderson, and R. Carpenter have been granted commissions as Flying Officers for the duration of hostilities.

AUXILIARY AIR FORCE: MEDICAL BRANCH

T. D. R. Aubrey to be Flight Lieutenant.

To be Flying Officers: E. C. Dayus, G. H. Duthie, H. J. Harcourt, J. G. Connell, and A. L. Cowan.

REGULAR ARMY RESERVE OF OFFICERS

ROYAL ARMY MEDICAL CORPS

Lieutenant A. M. Bennett, from Reserve of Officers, the Queen's Regiment, to be Lieutenant, with seniority November 8, 1938.

COLONIAL MEDICAL SERVICE

The following appointments are announced: W. M. Howells, M.B., Ch.B., D.P.H., Deputy Director of Medical Services, Gold Coast; F. R. Lockhart, M.B., Ch.B., Senior Medical Officer, Kenya; F. S. Paterson, M.B., Ch.B., Senior Medical Officer, Sierra Leone; D. A. Skan, M.R.C.S., L.R.C.P., Pathologist, Nyasaland; G. L. Broderick, M.B., B.Ch., and W. A. L. Tucker, L.R.C.P. and S.Ed., Medical Officers, Uganda; G. A. Burfield, M.B., B.Ch., Medical Officer, Northern Rhodesia; J. A. Crocket, M.B., Ch.B., Medical Officer, Gold Coast; E. W. R. Hackett, M.B., B.Ch., Medical Officer, Hong Kong; R. B. Heisch, M.B., B.Ch., Medical Officer, Kenya; W. Mullen, M.B., Ch.B., Medical Officer, West Africa; H. T. H. Wilson, M.R.C.S., L.R.C.P., Medical Officer, Tanganyika Territory.

The Library of the British Medical Association will be open from 9.0 a.m. to 5.0 p.m. (1.0 p.m. Saturday) until further notice.

British Medical Association

Diary of Central Meetings

OCTOBER

20 Fri. Journal Board, 11.30 a.m.

Areas of Stockport and Macclesfield Divisions

Notice is hereby given by the Council of the British Medical Association to all concerned that it is proposed to transfer the urban district of Cheadle and Gatley from the area of the Stockport Division to that of the Macclesfield Division.

Any member affected by this proposal and objecting thereto is requested to write to the Secretary of the Association by November 18, 1939, stating the objection and the ground therefor.

G. C. ANDERSON,
Secretary.

October 21, 1939.

Areas of Rochdale and Bury Divisions

With reference to the preliminary notice which appeared in the *Supplement* of September 2 (p. 171), notice is hereby given by the Council of the Association to all concerned that as from the date of this notice the municipal borough of Bacup is transferred from the area of the Rochdale Division to that of the Bury Division.

G. C. ANDERSON,
Secretary.

October 21, 1939.

Katherine Bishop Harman Prize

The Council of the British Medical Association is prepared to consider an award of the Katherine Bishop Harman Prize, of the value of £70, in the year 1940. The purpose of the prize, founded in 1926, is the encouragement of study and research directed to the diminution and avoidance of the risks to health and life that are apt to arise in pregnancy and child-bearing. It will be awarded for the best essay submitted in open competition, competitors being left free to select the work they wish to present, provided this falls within the scope of the prize. Any medical practitioner registered in the British Empire is eligible to compete. Should the Council of the Association decide that no essay submitted is of sufficient merit the prize will not be awarded in 1940, but will be offered again in the year next following this decision, and in this event the money value of the prize on the occasion in question shall be such proportion of the accumulated income as the Council shall determine. The decision of the Council will be final.

Each essay must be typewritten or printed in the English language, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address. Essays must be forwarded so as to reach the Secretary, to whom all inquiries should be addressed, British Medical Association House, Tavistock Square, London, W.C.1, not later than December 31, 1939.

Important Notice concerning Appointments

The attention of medical practitioners is drawn to the important notice concerning appointments which is published each week in the advertisement columns of the *Journal.* This notice asks practitioners to communicate with the Secretary of the British Medical Association before applying for any of the appointments listed therein. It appears this week at page 45.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

Section of Odontology.—Mon., 2.30 p.m. Presidential Address by Mr. S. F. St. J. Steadman: Condition of the Teeth in the Australian Aborigines.

Section of Orthopaedics.—Tues., 2 p.m. Paper by Dr. J. Trueta (late director of the department of surgery, General Hospital of Catalunya, Barcelona: Organization and Treatment of War Casualties. Members of the Sections of Anaesthetics, Medicine, Surgery, and United Services are specially invited to attend the meeting.

VACANCIES

EXAMINING FACTORY SURGEONS.—The following vacant appointments are announced. (*a*) Stanford-le-Hope (Essex); (*b*) Presteign (Radnorshire); (*c*) Handsworth (Yorkshire); (*d*) Abercrave (Breconshire); (*e*) Coleshill (Warwickshire). Applications to the Chief Inspector of Factories, Home Office, Whitehall, S.W.1, for (*a*), (*b*) (*c*) and (*d*) by October 24, and for (*e*) by October 31.

APPOINTMENTS

EXAMINING FACTORY SURGEONS.—H. G. B. Blackman, M.R.C.S., L.R.C.P., for the Wiveliscombe District (Somersetshire); G. D. Carter, M.R.C.S., L.R.C.P., for the Modbury District (Devonshire); Nancy B. Cox, M.R.C.S., L.R.C.P., for the Thame District (Oxfordshire); J. V. M. Davies, M.B., Ch.B., for the Shefford District (Bedfordshire); S. H. Martin, M.B., Ch.B., for the Nuneaton District (Warwickshire); F. W. Pringle, M.B., Ch.B., for the Moffat District (Dumfriesshire); H. J. C. C. Smith, M.B., Ch.B., for the Lauder District (Berwickshire).

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this heading is 9s. This amount should be forwarded with the notice, authenticated by the name and address of the sender, and should reach the Advertisement Manager not later than the first post Tuesday morning to ensure insertion in the current issue.

MARRIAGE

NICHOLSON-PIPER.—On Saturday, September 23, 1939, at St. Stephen's Church, Prenton, Birkenhead, by the Vicar, the Rev. Canon Briggs, Neville Jennings Nicholson, M.B., Ch.B.Ed., F.R.C.S.Ed., second son of the late Mr. and Mrs. George Nicholson, to Gwendoline Margaret Morton, elder daughter of Mr. and Mrs. H. V. Piper of Birkenhead, Cheshire.

DEATH

WALKER.—At Mqanduli, C.P., South Africa, on September 14, Patrick Hunter Walker, M.B., C.M.Glas., in his 82nd year.

SURGERY HOURS IN THE BLACK-OUT

The insurance committees of Manchester and Salford have agreed, after consultation with representatives of local panel and pharmaceutical committees, that chemists' shops in their areas shall close at 7 p.m. instead of 8 p.m. Practitioners are being urged, states the *Manchester Guardian,* to close their surgeries at the same hour, and also when visiting patients to issue prescriptions and certificates so far as practicable at the time of their visits. Insured persons are asked to co-operate by not making unnecessary demands on the services of the doctors, by attending, whenever possible, morning and afternoon surgeries, and by obtaining medicines from the chemists during the day time.

The third publication in the Ministry of Health's series of Emergency Medical Service Memoranda deals with the procedure to be followed by hospitals on the admission, transfer, discharge, or death of casualties, the provision of out-patient treatment, and the records that should be kept at each stage. This memorandum has already been circulated in typewritten form to medical officers of health, but this new issue contains some additions and amendments, including a revised copy of Form E.M.S. 105, which is the universal form of notification for all civilian casualties and Service and police casualties and sick admitted to hospital. Memorandum No. 3 may be obtained from H.M. Stationery Office, or through any bookseller (price 2d.).

WAR NOTICES

Transferred Practitioners

The British Medical Association has recommended that where practitioners in evacuation areas whose practices have wholly or mainly disappeared as a result of evacuation are transferred under the Central Emergency Committee's arrangement to reception areas they should be paid by their employing practitioners at a salary of £550 per annum with £100 in lieu of emoluments. Such transferred practitioners are required to conform to the Protection of Practices schemes operating in the area from which they move and the area to which they are transferred, and to enter into an appropriate bond with the employing practitioner and the Local Emergency Committee of the reception area not to practise there after the war.

It is necessary to point out that the practitioners transferred under this arrangement are senior, experienced practitioners of special value in augmenting medical services in a reception area or in replacing a practitioner who has joined the Services. It is not intended that this rate of remuneration should necessarily govern all appointments in all circumstances, or that the usual channels for obtaining assistants should not operate as in peace time. Practitioners will, however, realize the importance of requiring *all* incoming general practitioners to enter into an appropriate bond, a copy of which can be obtained either from the Local Emergency Committee or from this office.

Unaccompanied Children Scheme

The following are some typical queries received at this office concerning the unaccompanied children scheme:

1. *Q.*—What is the definition of an "unaccompanied child"?

A.—An "unaccompanied child" is a child boarded by the Government with a householder who receives payment for board and lodging at the rate of 10s. 6d. or 8s. 6d. a child—that is, a Form A child. Typically this is a child who is not accompanied by a parent or guardian under the same roof. There are, however, a small number of children who are accompanied by parents who have been evacuated as helpers rather than as parents; these are "unaccompanied children" within the meaning of the scheme.

2. *Q.*—A number of children, blind or nearly blind, were evacuated from London to a Home for the Blind in a southern county. No arrangements had been made for their medical care, and it was asked whether the local Unaccompanied Children Pool would include payments in respect of these children.

A.—The Home is a residential school, certified by the Board of Education. As the London County Council has power to send blind children there and pay the appropriate approved fee to the Home, the medical practitioner concerned in treating the children should submit his account in the normal way to the Home. The Home, on its part, would no doubt recover the fees in the account to the evacuating authority.

3. *Q.*—Mentally defective children were evacuated from London to a neighbouring county in three different camps. Will the local Unaccompanied Children Pool include remuneration in respect of such children?

A.—The general arrangement of such cases has been for the camp commandant to draw the billeting allowances on Form A for the whole party of children at the camp. The cost of medical attention should be met from the local Unaccompanied Children Pool.

4. *Q.*—What is the position regarding medical treatment of evacuated unaccompanied children under 5 boarded in nursery schools?

A.—These children are regarded as Form A cases and their medical treatment would accordingly come within the Unaccompanied Children Pool arrangements.

5. *Q.*—How will the amount to be paid to the pools administered by Local Emergency Committees be calculated?

A.—This will be done by negotiation between the Ministry of Health and the Central Emergency Committee on the basis of returns collected by the Evacuation Department of the Ministry. A provisional payment in respect of the four months ending December 31 will be made to the Local Emergency Committees in the month of December. This payment will consist of 2s. 6d. for all unaccompanied children in the October count now being made—that is, three-quarters of the amount due on the basis of this count. The final payment for this four-months period will be made next quarter, when all the figures for the period are available and the Ministry of Health and the Central Emergency Committee have, on the basis of these figures, agreed the final amount due. Next quarter there will be paid, in addition to the final amount for the four months ending December 31, a provisional sum in respect of the current quarter. Similarly in the following quarter there will be paid the final amount in respect of the preceding quarter and a provisional amount for the current quarter. Thus, individual practitioners will receive payment at the end of December and thereafter at the end of each quarterly period.

6. *Q.*—Does the 10s. capitation fee cover hospital care?

A.—It covers general practitioner care, similar in scope to that rendered under the National Health Insurance Acts. The institutional care of unaccompanied children will be provided at hospitals under the Government's Emergency Medical Service.

INSURANCE FOR MEDICAL WOMEN

BY

HENRY ROBINSON, M.D., D.L., J.P.

Honorary Secretary, Medical Insurance Agency

For those medical women who possess cars, own or occupy houses and flats, carry with them valuable property when they travel, or are thinking of purchasing an annuity with some or all of their capital, the advantages of doing their insurances through the Medical Insurance Agency are just as great as they are for medical men. These advantages were very fully set out last year in three articles published in these columns, a reprint of which can be obtained free on application to the manager of the Agency. Briefly, they are that when making use of the facilities offered by the M.I.A., which was founded in 1907 by Sir Dawson Williams and Sir Squire Sprigge, policies will be recommended only with first-rate companies (or, in the case of cars, underwriting groups); the contracts advised will ensure the maximum obtainable security compatible with competitive rates of premium; the free services of the Agency's expert managers are at disposal should any claim need to be put forward; and a substantial rebate of premium will be allowed to the insurer, thus reducing materially the cost of the insurance. The medical profession has during the past thirty-two years saved itself by such rebates over £100,000, which would otherwise have gone into the pockets of either the insurance companies or their agents, and has at the same time been the means of adding over £60,000 to the resources of the medical charities. It should perhaps be added here that the chairman of the Agency is Sir Humphry Rolleston; that no member of the Committee of Management is in any circumstances allowed to be remunerated directly or indirectly; that there are no shareholders; that the Agency is not itself at risk—it has no capital at all—but acts purely as honest broker; and that the interests of medical women have been safeguarded through their representation on the committee, first by Lady (Florence) Barrett, and then by Dame Barrie Lambert.

All this is, of course, no news to many medical women. It is repeated here in case there are some who have been hitherto unaware of it. But it will be observed that so far one or two of the most important aspects of insurance have not been touched upon, particularly life and endowment assurances in their protean forms. The problems which arise in connexion with these matters are no different in theory from those which confront medical men; but in practice the proportionate numbers of the two sexes for whom any particular type of assurance is the optimum do vary very considerably.

Women Doctors' Problems

When the requirements of a given medical woman's assurance happen to be the same as those of a given medical man, the advice of the Agency as to the best policy will, of course, be the same; but even then there are differences in the rates of premium which the offices charge for male and female lives, and these differences are wider in some companies than in others. But in a large number of cases the requirements of the medical woman are not the same as those of the (average) medical man, and it is in advising such clients as to the way in which their interests are best protected that the Agency renders to medical women a service which is quite unique. The justification of this claim is that the Agency is at pains not, as life assurance agents as a rule are, to promote the business of a particular office, but to give completely disinterested and unbiased advice conceived solely in the insured's interests.

When a medical woman has children or other dependants to protect her problems are not so very different from those of a similar medical man, except in so far as her husband's assurances and resources may relieve her of some or all of her responsibilities. It is, rather, the unmarried practitioner whose assurance needs are likely to require special consideration. There are, too, considerable differences between the problems set by those in private practice and those in permanent (usually pensionable) appointments.

The experience of the Agency shows that unmarried medical women in private practice tend to favour endowment policies maturing at earlier ages (commonly 50 to 55) than those most sought by medical men (commonly 60 to 65). It would seem that the majority of practising women contemplate the probability of retiring at earlier ages than men. No doubt the correspondingly heavier premiums required for the shorter dated policies are felt to be less of a drawback because of the (usual) absence of dependants. There is force in such reasoning when without profit policies are undertaken. But in the case of with profit endowment policies bonus accumulations are much less notable when the term set is less than twenty-five years compared with those accruing in the case of longer dated contracts, and unless the proposer feels quite certain that circumstances will not require continuance in practice beyond the ages above discussed it is probably wiser to take up endowment contracts for rather longer periods than most medical women embark upon—and, in addition, a given premium will assure a much larger capital sum at maturity.

Insurance for Salaried Officials

Whole life assurance has not been discussed, because to the proposer without dependants it is not of such importance or value; she who has them may be referred to the *Supplement* articles already mentioned. For the same reason there is no need here to dilate on the admirable combined pension, family income, and disability scheme fostered by the Agency some seven years ago and taken up on a very large scale by many medical men; it is fully explained in the same series of articles. The medical woman in a permanent pensionable post needs, however, in some cases special consideration. As in the case of men similarly employed, such practitioners have to contemplate superannuation at some given date—or often between certain limits of dates—on a pension considerably less than the salary hitherto enjoyed. They often feel that, as they do not need protection against early death (when they have no dependants), the normal endowment policy provides something—that is, cover against this contingency—which will not benefit them; and this attracts them towards policies assuring pensions beginning at the date when they expect to be superannuated. When such a policy is drawn in terms which mean that in the event of death before the pensionable age the company is freed of all liability—that is, retains all the premiums hitherto paid—it is clear that the premium quoted will be definitely cheaper than when return of premiums in the event of early death is included. This type of case raises very nice points of *pro* and *con*; for the argument as outlined above is often stultified by the fact that rebate of premiums for income tax purposes is allowed by the revenue only when there is an element of life protection: when an individual contract envisages a pension solely, the proposer is not eligible for this concession in respect of tax, which the new Budget has rendered more important even than it was before. It is on points such as this—and there are many others which space does not allow me to discuss—that the insurance experts who manage the Agency can be and are of the greatest help to intending proposers.

Sickness policies and annuities are two more branches of assurance on which expert guidance is most essential; and the Agency has a vast accumulated experience of these. Both medical women and medical men should fix firmly in their minds the principle that in their own interests they should take out no form of insurance whatsoever otherwise than through the organization set up to secure their protection—namely, the Medical Insurance Agency, B.M.A. House, Tavistock Square, W.C.1, and 6, Drumsheugh Gardens, Edinburgh.

The Secretary of State announces that he has withdrawn from Dr. Kenneth Rupert Tattersall of Plympton, South Devon, authority to be in possession of and to supply any drug or preparation to which the Dangerous Drugs Regulations, 1937, or any drug to which the Raw Opium, etc., Regulations, 1937, apply. Any person supplying Dr. Tattersall with any of the drugs or preparations to which these regulations apply, or supplying them on his prescription, will commit an offence against the Dangerous Drugs Acts.

HOW DOCTORS MAY SAVE PETROL

[From a Correspondent]

The restrictions on the use of petrol have fallen rather hardly on doctors, particularly as the initial allowances were so much below their necessary requirements. Now that larger rations are permitted there should be little difficulty in obtaining enough for the purposes of practice. In view, however, of the possibility of further restrictions in the future it behoves all practitioners to consider in what ways the consumption of petrol may be diminished. It is too much to expect that war, which has upset so many households and so much business, should not necessitate some alterations in the doctor's daily round and some personal sacrifices in the common cause.

A diminution in the amount of petrol required by a doctor may be brought about in three ways: by rearrangement of work, by the use of alternative methods of transport, and, in some cases where this is possible, by the use of a car which is more economical in petrol consumption. There are doctors who attend daily, sometimes several times a day, at surgeries which may be situated two or even three miles apart; in war time patients could hardly complain if the number of visits to any one surgery were diminished. One daily visit to each surgery could be made to suit most patients if it was made in the morning and evening on alternate days. While it is impossible to avoid the occasional urgent long-distance call, yet in the regular run of practice much petrol may be saved by systematically arranging to visit all patients in a distant part of a practice at one time. In some instances it might be possible to come to an amicable arrangement with another doctor, who might visit any special case which happened to be in his district.

Many doctors who appreciate the need for economy have already adopted alternative methods of transport. In urban districts they have found that a great number of near-by visits may be made on foot, while in certain suburban areas they have been wise enough to have recourse to a long-disused bicycle. In some parts, particularly in cities, buses and trams may often serve for certain journeys as well as or better than a car. There is little doubt that time as well as petrol may often be saved by making use of electric trains when crossing from one part of London to another. A special problem is raised by the patient who has removed to a distance and still wishes to be attended by the trusted doctor. It may be necessary to use the car, if no arrangements with a near-by doctor can be made, in areas which have no transport facilities, but it is difficult to see the need for a car when excellent train services are available. For example, any doctor in London who wishes to visit patients on the South Coast will find transport by electric train more speedy and as cheap as travel by motor car. In other cases long-distance bus services can easily be used as alternatives.

Some doctors possess two or more cars. Usually one of these is small and economical in petrol consumption, the other larger and more extravagant to run. With large bags or apparatus to carry the doctor may find the small car rather inconvenient for the exigencies of practice, but the discomfort might well be endured for the sake of saving petrol at the nation's need. Many doctors have as their only car one with a high horse-power, which will perhaps only travel ten or twelve miles per gallon of petrol. If they considered that saving of petrol was a national duty they might perhaps wish to acquire a smaller and more economical car for the duration of the war. The writer of this note has laid up a 24-h.p. car and bought a 9-h.p. one, which uses half the amount of petrol consumed by the larger vehicle. He has also (in the sixth decade of life) bought a bicycle, and finds that the new regime is rather exhilarating.

The Library of the British Medical Association will be open from 9.0 a.m. to 5.0 p.m. (1.0 p.m. Saturday) until further notice.

Correspondence

Remuneration and Grading in the Emergency Medical Service

Sir,—In your footnote to my letter in the *Supplement* of October 14 (p. 206) it is stated that the Ministry of Health has decided not to "remunerate from Government sources practitioners holding whole-time voluntary hospital or local authority hospital appointments." It is perhaps unnecessary to point out that while the latter are already, in effect, Government employees, and as such are liable to obey orders, the former are not. This leads to two questions: (1) By what right can the Ministry demand that voluntary hospital medical officers shall attend air raid casualties without payment? (2) Whether it is compulsory to perform such work under existing agreements. It must not be forgotten that the salaries received for certain voluntary hospital appointments are already inadequate. I submit, Sir, that this decision, making as it does an invidious distinction between different branches of the profession, is entirely unsatisfactory. In case I should be accused of a mercenary attitude let it be said that I am fully prepared to give my services without payment provided everyone else does the same. The views of others on this subject would be interesting.—I am, etc.,

Wakefield, Oct. 18. John A. G. F. Rose.

A Generous Action

Sir,—I have received the following letter which I am confident will have the sympathetic approval of your readers.

RUTLAND PANEL COMMITTEE

Dear Sir,

At its meeting to-day the Rutland Panel Committee decided to abandon its annual dinner usually held in November. It was felt that the money usually spent on this function should be devoted to medical charities, and in view of the many claims on the Royal Medical Benevolent Fund, and its probable drop in income from high taxation, the committee has asked me to send you a cheque for fifteen guineas, the approximate sum we usually spent on our dinner.

Yours faithfully,
(Sgd.) Gordon Purdy,
Hon. Secretary.

As honorary treasurer of the Fund I would like to state how greatly the committee appreciates not only the generous action but also the spirit which underlies the gift. May I suggest, therefore, that the example of the Rutland Panel Committee is one which might well be followed by other committees or clubs of every variety when an occasion arises.—I am, etc.,

Lewis G. Glover,
Honorary Treasurer, Royal Medical Benevolent Fund.
Wormingford Grove, Wormingford, Essex,
Oct. 23.

The Children's Nutrition Council (formerly the Children's Minimum Council) has decided that its work shall continue during war time. It is considered that with war control of foodstuffs it is more than ever necessary to have an organization that can consider the best means of using the existing social services to ensure that children and their mothers are being adequately nourished. Further, the council is concerned with the adequacy of children's allowances under the many different regulations covering the families of soldiers, the unemployed, and other sections of the community, and will press for an increase where the allowances are too low to ensure an adequate standard of nutrition. It urges the establishment of community centres for the feeding and social life of both evacuated persons and the normal population in reception areas, the provision of midday meals for *all* school children in such areas, and the adoption of or extension of existing schemes for free and cheap milk. The address of the Council is 72, Horseferry Road, S.W.1.

Naval, Military, and Air Force Appointments

ROYAL ARMY MEDICAL CORPS

Colonel F. T. Rees, M.C., has relinquished his commission and retains his rank with permission to wear the prescribed uniform.

Major N. W. Hammer has relinquished his commission and retains his rank with permission to wear the prescribed uniform.

Majors F. D. Marsh, M.C., A. O. Bekenn, and R E Holme, from Territorial Army Reserve of Officers, R.A.M.C., to be Majors.

Captain H. Miller, from Territorial Army Reserve of Officers, to be Captain.

Captain W. G Bisset has relinquished his commission.

Lieutenants R. R. Davies, P. D. Stewart (seniority October 22, 1938), H. M. S. G. Beadnell, and W Windsor to be Captains.

To be Captains: Captains J. Kerr, J. H. B. Livingston, D M. Mackenzie, K. M. Morris, E. F. S. Morrison, J. O'Donnell, T. H. Sansome, and R. A. M. Scott (from Territorial Army Reserve of Officers, R.A.M.C.), and Lieutenant J. A. Robertson, late R.F.A.

To be Lieutenants: A. W. F. Catto, G. Macpherson, T. A. Blyton, D. R. Beaton, W. O. Whittaker, H. Freeman, I. B. McCrae, P. C. A. Posford, C. W Horncastle, F. J. Fell (from Regular Army Reserve of Officers, R.A.M.C.), F. M. Halley (from Territorial Army Reserve of Officers, and relinquishes rank of Captain), J. H. Hannan, J A. Hart, W. L. Petter, H. A. Constable, E. M. K. Jellicoe, J. A. Dunlop, D. W. Gillies, W. A. Heggie, J. H. B. Beal, G. D. Hadley, W. Chalmers D A. Brigg, I C. Robertson, R. W. W.-Brown, C. O. Barnes, W. Mayne, E. Whyte, Lieutenants D. L. Greig and C. W. F. Outred (from Territorial Army Reserve of Officers, R.A.M.C.), W N. Miller, E. J. M. Gallagher, and S. E. Gordon.

To be Lieutenants (on probation): H. F. L. Gallaher, W. MacK. McLennan, Captain G. E. Gray (from R.A.M.C., T.A.), H L. Connor, I. D. Paterson, I. W. H. Mansfield, R. S. McGeorge, D. G. Howatson, D A. Bird, C. D. Salmond, and D. B. Jagger.

Lieutenants (on probation) W. MacK McLennan and D. B. Jagger are seconded under the provisions of Article 213, Royal Warrant for Pay, 1931, from September 1.

REGULAR ARMY RESERVE OF OFFICERS

ROYAL ARMY MEDICAL CORPS

Captain T. S. Cave (from Regular Army Reserve of Officers) to be Captain, with seniority November 13, 1936.

Captain I. S. Thompson has resigned his commission.

Lieutenant A. H. Levers has resigned his commission.

L. W. H. Bertie, late Second Lieutenant, Special List, to be Lieutenant.

SUPPLEMENTARY RESERVE OF OFFICERS: ROYAL ARMY MEDICAL CORPS

Captain A. H. L. Baker has resigned his commission

Lieutenant A. M. Critchley to be Captain.

To be Lieutenants: C. V. Oldroyd, R. Cox, H. S. Davis, T. J. Fairbank, D. P. Kearns, R. G. M. Longridge, W. M. Macleod, P H. Newman, I. N. Samuel, G. C. Steel F. R Store, and F. A. D'Abreu.

TERRITORIAL ARMY

Lieutenant-Colonel W. Leslie, M.C., from R.A.M.C., T.A., to be Colonel and A.D.M.S., 6th Anti-Aircraft Division, Territorial Army.

ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel and Brevet Colonel D. W Boswell, T.D., has vacated the appointment of Officer Commanding, 3rd Eastern General Hospital.

To be Majors: Captain F. Roberts, R. W. Butler, L. B. Cole, R. Brooke, A. S H. Walford, and E. G. Recordon.

Captain H. C. M. Williams has resigned his commission.

To be Captains: Lieutenant F. A R. Stammers (late R.G.A., Special Reserve), Lieutenant J. F. Hinksman (late Border Regiment), Lieutenant W. R. Blunt (late R.G.A., Special Reserve), Second Lieutenant L. A. Ogg (late R.T.C.), E. V. Bevan, E. C. Campbell, W H. Lewis, L. W. Lauste, H. K. Ashworth, A. F. Alsop, R. L. Holt, E. Bulmer, E. G. Collins, A. R. Kelsall, D. E. O'C. Cuffey, T. D. Day, and Captain J. A. Tomb (from Territorial Army Reserve of Officers, R.A.M.C.).

To be Lieutenants: D. C. Langwell, J. H. Bolton, S. W. G. Hargrove, P. F. Evans, F. Elliott, J. Watson, J. H. Levack, D. W. Lacey, W. Michie, F. M. Newnham, J. Clark, G. H. G. Hope, H. R. Fosbery, J. A. R. Johnson, T. W. H. Porter, E. G. Wilbraham, K D. Moynagh, R. Pollock, L. G C. Pugh, and A. F. McDonald.

The notification regarding the appointment of Lieutenant E. V. Bevan in the *London Gazette* of May 12, 1939, has been cancelled.

TERRITORIAL ARMY RESERVE OF OFFICERS: ROYAL ARMY MEDICAL CORPS

Captain S. C. Swinburne (late R.A.M.C., Special Reserve) to be Captain.

INDIAN MEDICAL SERVICE

Colonel D. C. V. FitzGerald, M.C. has retired from the Service.

Lieutenant-Colonel R. Clifford, D.S.O., M.C., has retired from the Service

The services of Lieutenant-Colonel M. M. Cruickshank have been placed permanently at the disposal of the Government of Madras, as from May 10, 1934.

The services of Lieutenant-Colonel A. C. L. O'S. Bilderbeck have been replaced at the disposal of the Defence Department, as from August 2, 1939.

The provisional promotion of Major S. M. Kharegat to his present rank has been confirmed.

Captain J. W. Richmond has retired from the Service.

Captain W. S. Morgan has been appointed an Agency Surgeon and posted as medical officer in charge of the Crown Representative's Police Force Hospital, Neemuch, as from August 20.

Captain R. I. Reid, on appointment to the Medical Stores Department as a temporary measure, has been posted as Deputy Assistant Director-General (Medical Stores), Medical Store Depot, Lahore Cantonment, as from August 15.

Captains (on probation) P. B. Cussack and N. P. Woodgate-Jones have relinquished their probationary appointments

Lieutenant (on probation) J. A. Anderson to be Captain (on probation).

Lieutenant (on probation) H. Rees has been restored to the establishment, with seniority May 1, 1938.

Important Notice concerning Appointments

The attention of medical practitioners is drawn to the important notice concerning appointments which is published each week in the advertisement columns of the *Journal.* This notice asks practitioners to communicate with the Secretary of the British Medical Association before applying for any of the appointments listed therein. It appears this week at page 39.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

Section of Comparative Medicine.—Wed., 2.15 p.m. Presidential Address by Dr. C. H. Andrewes: Latent Virus Infections, with Special Reference to Cancer. The address will be open to general discussion. All Fellows and particularly members of the Section of Pathology are invited to attend.

Section of Otology.—Fri., 10 a.m. Presidential Address by Dr. T. Ritchie Rodger: Syphilis as seen by the Aural Surgeon. A discussion will follow.

Section of Laryngology.—Fri., 2.30 p.m. (Cases at 1.30 p.m.). Presidential Address by Mr. T. B. Layton: Clinical Rhinology. Cases will be shown.

Section of Anaesthetics.—Fri., 2.30 p.m. Presidential Address by Dr. Harold Sington: Yesterday and To-day in Children's Anaesthesia.

VACANCIES

MEDICAL REFEREE UNDER THE WORKMEN'S COMPENSATION ACT, 1925, for the County Court Districts of Bromley and Sevenoaks (Circuit No. 56). Applications to the Private Secretary, Home Office Whitehall, S.W.1, by November 16.

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this heading is 9s. This amount should be forwarded with the notice, authenticated by the name and address of the sender, and should reach the Advertisement Manager not later than the first post Tuesday morning to ensure insertion in the current issue.

MARRIAGE

KEERS—LOCKIE.—At the High Kirk, Dunoon, on September 29, 1939, by Rev. G. Charles Smith, M.C., M A. Robert Young Keers, M.D., son of Rev. William and Mrs. Keers, Newbliss, Co. Monaghan, to Jessie Cameron, elder daughter of the late Major Andrew Lockie and of Mrs. Lockie, Ranikhet, Dunoon, Argyll.

DEATH

ROBB.—On October 16, 1939 (suddenly), at 13, Wake Green Road, Moseley, Birmingham (the residence of his sister) William Hunter, M.B., C.M.(Edin.), in his 64th year. Interred at Caerlaverock, Dumfries, on October 20, 1939.

Corrigendum

Wing Commander A. J. Brown, D.S.O., M.R.C.S., L.R.C.P., is a Hospital Officer of the Ministry of Health, not a Deputy Hospital Officer as stated in the *Supplement* of October 14 (p. 202).

WAR NOTICES

Emergency Medical Service

It will be recalled that in July the Central Emergency Committee, at the request of the Ministry of Health, put forward specific proposals for the terms and conditions of service of an Emergency Hospital Medical Service. It was recommended that there should be two types of appointment within the Service: a Class A or whole-time appointment, and a Class B or part-time appointment. It was further recommended that an establishment of Class A officers should be laid down by the Ministry. In general the Ministry accepted the Committee's recommendations, modifying those relating to salaries but not embodying a proposal that special rates of compensation for death or injury should be paid or the recommendation that a Class A establishment should be laid down.

Recruitment to the Service was then undertaken by the Ministry of Health, with the result that about 2,000 practitioners, apart from house officers, were enrolled in the London area, over two-thirds of them on a whole-time basis. In the provinces over 3,000 practitioners were enrolled, comparatively few of them being on a part-time basis. It was not long before the hurried recruitment of whole-time officers without a fixed establishment led to difficulties in London. Some whole-time officers enrolled in the belief that they could at the same time continue in private practice. Others, enrolled but not called up at the outbreak of war, complained that their private practices had disappeared. Some attended their hospitals at the outbreak of war under a misapprehension.

In order to meet a part of the problem the Ministry offered whole-time officers officially called up the opportunity of transferring to a part-time basis, remaining liable for four-sevenths of their time and receiving one-third of their whole-time salary. This offer was acceptable to few and the situation remained practically unchanged. Difficulties arose, too, in connexion with house officers, some of whom, although enrolled, were informed by the Ministry that they were enrolled in error. In the part-time B section difficulties were beginning to arise as to the interpretation of the section of the terms and conditions of service defining the range of professional work falling within the scope of the Service. There were other difficulties also as a result of the Ministry's grading of Class B officers into those undertaking consultant and specialist work and those undertaking general practitioner work.

At this stage the Central Emergency Committee decided to give immediate consideration to the position with a view to the preparation of a scheme of reorganization for recommendation to the Minister of Health. It established a special committee for the purpose, including the Presidents and representatives of the three Royal Colleges. The full personnel of the Committee was given by the Minister in answer to a question in the House of Commons and is set out in full in this *Supplement* at page 216. This committee, after collecting the views of the various groups affected, has now prepared a considered scheme for the reorganization of the Service, and it has asked the Minister of Health to receive a deputation in order that this scheme may be placed before him. It relates both to whole-time and to part-time officers. The Minister has consented to receive the deputation on Friday, November 3.

The General Practitioner and Air-raid Casualties

The Minister of Health has decided to establish on a temporary basis a domiciliary medical service for all civilians who sustain war injuries in this country if in-patient treatment is no longer necessary or is impracticable and treatment as an out-patient of a hospital is impracticable. In so far as the injured persons are entitled to medical benefit under National Health Insurance they are already provided for. The scheme will be available for dealing with the residue.

Service under the scheme will be confined to after-treatment of the war injury and to treatment within the scope of a general practitioner. The British Medical Association has agreed with the Ministry to use its best endeavours to secure that medical practitioners throughout the country will take part in the service as they have recently done in the case of the service for the medical treatment of unaccompanied children. Payment to general practitioners will be made on the basis of a capitation fee at the rate of 16s. per annum for each person attended under the scheme, this sum being exclusive of drugs and dressings.

The scheme is to be liable to reconsideration at the end of a year. It will cover one further small class of case, that of civil defence volunteers who sustain "war service injuries" as defined in the Personal Injuries (Emergency Provisions) Act, 1939.

This is a preliminary announcement and the fullest details will soon be made available to Local Emergency Committees and to individual practitioners.

Casualties in Rural Areas

A question has been raised as to the medical provision for attendance on casualties due to air raids in rural areas in which no fixed first-aid posts have been established. This matter has been taken up with the Ministry of Health, which replies as follows:

"It has not been found practicable to provide organized arrangements for providing medical attention for air-raid casualties other than those who are treated at first-aid posts (mobile or fixed) or hospitals. It will be appreciated that in the great majority of cases any necessary treatment can be provided through those agencies, and any system under which the private practitioners were called upon to give treatment would need to be subject to proper control. In any exceptional case, however, where medical services were required by a casualty who could not be treated through the organized arrangements, a claim for payment would receive special consideration in the event of the patient not being an insured person, or being unable to make his own arrangements for payment."

CENTRAL EMERGENCY COMMITTEE
(Central Medical War Committee),
British Medical Association House,
Tavistock Square, W.C.1.

EMERGENCY MEDICAL SERVICE

In reply to a question in the House of Commons on October 26, on the consultations that have taken place between the Ministry of Health and representatives of the medical profession concerning the terms and conditions of service in the Emergency Medical Service, Dr. Elliot circulated the following lists of personnel of the Central Emergency Committee (Central Medical War Committee), Group Officers, and a special committee appointed by the Central Emergency Committee on October 18. The first part of Dr. Elliot's reply will be found in "Medical Notes in Parliament" this week (*Journal*, p. 933).

CENTRAL EMERGENCY COMMITTEE (CENTRAL MEDICAL WAR COMMITTEE)

Chairman of Council: Mr. H. S. Souttar, London.
Chairman of Representative Body: Dr. H. Guy Dain, Birmingham.
Treasurer and Chairman of General Practice Committee: Dr. J. W. Bone, Luton.
Chairman of Naval and Military Committee: Colonel A. H. Proctor, London
Chairman of Public Health Committee: Professor R. M. F. Picken, Cardiff
Chairman of Welsh Committee: Dr. W. E. Thomas, Ystrad Rhondda, Glam.
Chairman of Insurance Acts Committee: Dr. E. A. Gregg, London.
Chairman of Rural Practitioners Subcommittee: Dr. D. G. Greenfield, Rushden, Northants.
Chairman of Hospitals Committee: Dr. Peter Macdonald, York.
Chairman of Organization Committee: Dr. J. C. Matthews, Downton, Wilts.
Chairman of Public Medical Services Subcommittee: Dr. H. W. Pooler, Ashover, Derbyshire.
Chairman of Special Practice Committee: Professor A. H. Burgess, Cheadle, Cheshire.
Representative of Society of Medical Officers of Health: Dr. James Fenton, Kensington.
Representative of Medical Women's Federation: Dr. Letitia Fairfield, London.
Representative of Medical Committee of House of Commons: Sir Francis Fremantle, Hatfield.
Representatives of following Group Committees:
  Radiological: Dr. Russell J. Reynolds, London.
  Pathological: Dr. D. Embleton, London.
  Ophthalmological: Mr. J. D. M. Cardell. London.
  Consultants and Specialists: Mr. A. Hedley Whyte, Newcastle-upon-Tyne.
  Psychological Medicine: Dr. A. A. W. Petrie, Sutton, Surrey.
  Physical Medicine: Dr. C. B. Heald, London.
  Orthopaedic: Mr. Harry Platt, Manchester.
Two Representatives each of: Royal College of Surgeons: Sir William Girling Ball, London; Sir Alfred Webb-Johnson, London. Royal College of Physicians: Dr. A. E. Clark-Kennedy, London; Sir Charles Wilson, London.
Representative of Royal College of Obstetricians and Gynaecologists: Professor W. Fletcher Shaw, Manchester.
Representative of Medical Research Council: Dr. P. N. Panton, London.
Four General Practitioners appointed by the British Medical Association on a territorial basis: Dr. J. A. Brown, Birmingham; Mr. G. E. Elkington, Newport, Shropshire; Sir Kaye Le Fleming, Wimborne; Dr. S. A. Winstanley, Urmston, Lancs.
Representative of Board of Education: Dr. J. Alison Glover.
Representative of Board of Control: Sir Hubert Bond.
Liaison Officer of Scottish Emergency Committee: Dr. R. W. Craig, Edinburgh.
Liaison Officer of the Northern Ireland Emergency Committee: Dr. F. M. B. Allen, Belfast.
Secretary (Dr. G. C. Anderson).
Deputy Secretary (Dr. Charles Hill).

Group Officers: London

Sector I.—Mr. Russell J. Howard.
" II.—Dr. A. E. Clark-Kennedy.
" III.—Sir Girling Ball.
" IV.—Dr. Wilfred Pearson.
" V.—Dr. H. E. A. Boldero.
" VI.—Sir Charles Wilson.
" VII.—Mr. C. H. S. Frankau.
" VIII.—Professor O. L. V. S. de Wesselow.
" IX.—Mr. John Hunter.
" X.—Professor T. B. Johnston.

Group Officers: Provinces

Birmingham.—Professor L. G. Parsons.
Liverpool.—Mr. K. W. Monsarrat.
Manchester.—Professor A. H. Burgess.
Sheffield.—Dr. A. G. Yates.
Leeds.—Mr. Harold Collinson.
Bristol.—Professor Hey Groves.
Newcastle.—Mr. F. C. Pybus.
Hull.—Dr. T. Ritchie Rodger.
Bradford.—Dr. J. F. Allan.
Stoke-on-Trent.—Dr. E. C. Myott.
Portsmouth.—Mr. B. Wagstaff, Secretary, Royal Portsmouth Hospital (with an advisory committee of four medical men).
Southampton.—Mr. E. L. Wirgman, Secretary of Royal South Hants and Southampton Hospital (with an advisory committee of four medical men).
Brighton.—Dr. L. A. Parry.
Wolverhampton.—Mr. W. H. Harper, House Governor, the Royal Hospital, Wolverhampton.
Walsall.—Dr. Robert Forrest.
Reading.—Dr. G. O. Lambert.
Oxford.—Major-General Sir Robert McCarrison.
Exeter.—Colonel R. Pickard.
Nottingham.—Dr. W. T. Rowe.
Leicester.—Dr. John P. W. Jamie.
Coventry and Warwick.—Mr. G. G. Alderson.
Derby.—Dr. F. G. Lescher.
Sunderland.—Dr. Paige C. Arnold.
Cambridge.—Professor J. A. Ryle.

Wales

Cardiff.—Dr. R. Armstrong.
Newport.—Mr. Alan Ruddle.
Swansea.—Mr. O. C. Howells.

Special Committee

Representing the Royal College of Physicians of London:
  Sir Robert Hutchison (President) Dr. H. L. Tidy.
Representing the Royal College of Surgeons of England:
  Mr. Hugh Lett (President), Sir Alfred Webb-Johnson.
Representing the Royal College of Obstetricians and Gynaecologists:
  Professor W. Fletcher Shaw (President), Dr. J. P. Hedley.
Representing the Group Officers:
  London:
    Sir Charles Wilson, Sir Girling Ball, Dr. H. E. A. Boldero.
  Provinces:
    Professor A. H. Burgess, Mr. K. W. Monsarrat, Professor L. G. Parsons.
Representing the Central Medical War Committee:
  Mr. H. S. Souttar (Chairman), Dr. H. Guy Dain, Dr. A. E. Clark-Kennedy, Professor R. M. F. Picken.
  Dr. G. C. Anderson (Secretary).
  Dr. Charles Hill (Deputy Secretary).
Representing the London County Council:
  Dr. W. A. Daley.
Attending by invitation:
  Sir Maurice Cassidy, Mr. R. M. Vick.

At a meeting with the Minister of Health (Dr. Elliot) on October 27 a deputation from the British Paediatric Association, which was introduced by Dr. Charles McNeil, professor of child life at Edinburgh University and physician to the Royal Sick Children's Hospital, Edinburgh, suggested: (*a*) that the Government should appoint a paediatrician to act as consultant or adviser to the Minister, just as consultants had been appointed for special work like facial surgery under the Emergency Medical Scheme; (*b*) the appointment of specialists in children's illnesses, who would, in co-operation with general practitioners and public health authorities, be responsible for the children in the receiving areas; (*c*) the allocation of special blocks of beds and the concentration on those beds of specially trained children's doctors and nurses for sick children in the receiving areas.

The Minister, in reply, said that the appointment of a consultant in children's illnesses was not analogous to the appointment of consultants on such things as facial surgery in the Emergency Medical Service, since the latter would deal with casualties caused by air raids, whereas the former would be dealing with ordinary illnesses and not injuries arising from raids. But while he would gladly consider their suggestions and particularly their offer to set up panels of specialists in the different emergency regions so that general practitioners in the reception areas might have the advantage of consultants' services, he doubted whether evacuation could properly be made the occasion for the institution of a new service not available in peace time. The evacuated children represented only a small proportion of the total child population of the country, and if a specialist children's service were to be made available as part of the public health services it would need to cover children generally and not merely those who had been evacuated.

Assurance for Doctors

Meeting the Premium on Life Policies

It is possible that, with increased taxation and, in some instances, reduced income, medical men may find it difficult, temporarily, to meet the premium on their life insurance policies, and may even go so far as to contemplate surrendering those life policies. Now more than ever before is it necessary to maintain life assurance protection at its highest level, and very careful thought should be given to the following suggestions before any decision is taken which means surrendering a valuable policy.

A life policy can be turned into a "paid-up" assurance, which means for practical purposes that the sum assured is reduced in the proportion that the number of premiums actually paid bear to the total number which would have been paid if the contract ran to maturity. This is a much better proposition than surrendering a policy, but it still means a reduction in cover.

Most companies have special regulations for assisting a policy-holder to keep his cover intact during temporary financial embarrassment, and this is generally done in one of two ways. First, there are "non-forfeiture regulations" whereby, if the policy carries a sufficient surrender value, the premium is automatically advanced by the company out of the surrender value, and the policy-holder merely pays interest on the premium so advanced and is at liberty to repay this premium at his convenience. The procedure can be prolonged while the surrender is sufficient for the purpose. Secondly, a loan, where the surrender value justifies it, which is sufficient to pay the premium outstanding can be obtained from the company, at interest, on the security of the policy, and this loan can be repaid later or remain a charge on the policy to be deducted from the moneys due at maturity. Both these methods have the great advantage of keeping the cover at its full value and also of retaining in force a contract which, if surrendered or paid up, cannot perhaps be reinstated, for medical or other reasons, when desired.

Naval, Military, and Air Force Appointments

ROYAL NAVAL MEDICAL SERVICE

Surgeon Captain F. C. Wright has been placed on the retired list.

Surgeon Lieutenant J. G. More-Nisbett to be Surgeon Lieutenant Commander.

To be Surgeon Lieutenants: R. M. Coplans, J. C. G. Evans, P. S. Fuller, J. F. Hughes, K. R. Kennedy, D. A. Prothero, D. L. Ridout, M. Urie, J. C. Wyatt, C. V. Arthur, J. M. Couchman, A. Donald, P. B. Nicol, W. M. Davidson, E. S. Elliott, N. L. Fox, A. L. W. Robinson, E. F. G. Stewart, and S. L. A. Clarke.

ARMY MEDICAL SERVICES

Major-General J. W. L. Scott, D.S.O., K.H.P., late R.A.M.C., from Deputy Director to be Director of Medical Services, Eastern Command.

ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel C. J. Blaikie has retired and retains his appointment.

Major H. P. Rudolf, M.C., to be Lieutenant-Colonel.

Major E. White, from R.A.M.C. (T.A.), to be Major.

Captain A. D. Bourne has relinquished the appointment of Deputy Surgeon.

Captain D. T. Swift has been appointed to a permanent commission, retaining his present seniority. (Substituted for the notifications in the *London Gazette* of June 29, 1934, June 7, 1935, and June 6, 1939.)

Lieutenant D. T. Swift to be Captain, with seniority June 7, 1934.

The appointment of Lieutenant D. T. Swift has been antedated to June 7, 1933, under the provisions of Article 36, Royal Warrant for Pay, 1931, but not to carry pay and allowances prior to June 7, 1934.

Lieutenant T. H. Howell (emergency commission) to be Deputy Surgeon.

Lieutenant P. Kennedy has ceased to hold a commission.

Lieutenants (on probation) G. J. Harrisson, G. M. Barling, W. A. Groom, D. B. Jagger, and G. P. Crean have been restored to the establishment.

The following Lieutenants (on probation) have been confirmed in their rank: J. H. Prain, W. A. Groom, F. J. Ingham, M. F. X. Slattery, G. J. Harrisson, J. A. Allen, E. P. Jowett, N. F. Field, W. L. O'Donnell, W. B. Foster, J. C. B. Nesfield, R. A. R. Topping, C. E. Brown, R. H. C. Manifold, N. E. O'Neill, C. J. Murray, A. R. T. Lundie, D. S. Milne, G. M. Barling, L. A. S. Edmondson, T. C. Hallinan, P. B. Williams, I. O. B. Spencer, G. G. Black, S. P. Bellmaine, H. F. L. Gallaher, W. M. McLennan, G. E. Gray, H. L. Connor, I. D. Paterson, I. W. H. Mansfield, R. S. McGeorge, D. G. Howatson, D. A. Bird, C. D. Salmond, and D. B. Jagger.

To be Lieutenants: T. C. Keble, R. H. S. Langeveld, D. A. D. Kennedy (temporarily relinquishes rank of Captain), F. F. Langridge, R. G. Bannerman, L. Godlove, C. S. Humphries, and H. G. Gibson.

ROYAL AIR FORCE MEDICAL SERVICE

Flight Lieutenant A. W. St. C. Greig has resigned his short service commission.

ROYAL AIR FORCE VOLUNTEER RESERVE

Sir John D. Pollock, O.B.E., has been granted an honorary commission as Wing Commander while serving as Royal Air Force representative on University Joint Recruiting Boards.

ROYAL AIR FORCE VOLUNTEER RESERVE: MEDICAL BRANCH

K. C. Donovan has been granted a commission as Flight Lieutenant for the duration of hostilities.

Flying Officers D. M. Wallace, W. A. S. Falla, H. A. Tracey, R. G. H. Cunningham, W. Hargrave-Wilson, C. R. Jenkins, B. E. Rayner, G. P. Arden, J. C. McC. Browne, W. H. Gossip, L. S. Henry, J. C. McGregor, K. Fawssett, C. R. Mayou, C. O. Gange, I. B.-K. Macgregor, R. J. Owen, W. Simpson, A. K. Thomas, R. E. Angel, D. M. Brown, R. H. Craig, C. Hotson, T. S.-B. Kelly, D. A. Ker, J. B. Maurice, W. Milligan, G. MacK. Gibson, B. J. E. Anson, L. G. Anderson, H. S. Atkinson, C. G. Burgess, P. R. Kemp, H. S. H. O'Conor, R. W. Stewart, M. L. Maley, H. E. Pooler, B. S. Robertson, K. W. Bruce, D. G. Evans, D. H. Le Good, R. I. Shier, G. B. Grayling, F. G. Mundell, J. H. Hall, H. J. Davies, D. M. Hannah, R. Hill, A. Wilson, H. J. H. Hendley, J. B. Methven, F. R. Neubert, J. D. Ramsay, H. J. Simmons, D. Skinner, W. MacP. Cross, J. A. Mains, T. C. Wilson, J. Courtney, W. Heath, F. J. G. Jefferiss, and A. J. Owston to be Flight Lieutenants.

D. D. MacDonald, I. S. Buchanan, N. Jackson, W. M. Philip, J. L. Trent, D. P. Rowe, W. J. C. Anstie, D. McGregor, J. H. P. Gauvain, M. J. Lange, H. W. Whittingham, F. L. E. Musgrove, and F. L. Patterson have been granted commissions as Flying Officers for the duration of hostilities.

AUXILIARY AIR FORCE: MEDICAL BRANCH

J. Noble and H. J. Riley have been granted commissions as Flying Officers.

REGULAR ARMY RESERVE OF OFFICERS

ROYAL ARMY MEDICAL CORPS

Major E. L. Fyffe has ceased to belong to the Reserve of Officers on account of ill-health.

Major D. C. Ogilvie, late R.A.M.C., temporary commission, to be Major, with seniority November 4, 1938.

To be Captains: Captain H. L. G. Hughes, D.S.O., M.C., late R.A.M.C., with seniority May 6, 1937, and Captain J. A. Tolmie, late Captain, R.A.M.C., Special Reserve, with seniority February 13, 1938.

Lieutenant A. H. W. Fleming, from Regular Army Reserve of Officers, Royal Norfolk Regiment, to be Lieutenant, with seniority July 31, 1925.

SUPPLEMENTARY RESERVE OF OFFICERS: ROYAL ARMY MEDICAL CORPS

Lieutenants A. C. Stevenson and D. A. Lowe to be Captains.

To be Lieutenants: G. Bourne, I. H. Griffiths, J. C. Harland, E. H. C. Harper, G. Lorriman, and R. R. Simpson.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Lieutenant J. Beattie, from Territorial Army Reserve of Officers, R.A.M.C., to be Acting Colonel and Director of Army Blood Transfusion and Surgical Research Laboratory.

Lieutenant-Colonels J. M. Smith and W. R. Watt have resigned their commissions and retain their rank with permission to wear the prescribed uniform.

Lieutenant-Colonels T. A. Hindmarsh and J. T. Kyle have relinquished their commissions on account of ill-health and retain their rank with permission to wear the prescribed uniform.

Lieutenant-Colonels T. E. A. Carr, J. O. Thomas, M.C., T.D., and J. S. M. Connell, from Territorial Army Reserve of Officers, R.A.M.C., to be Lieutenant-Colonels.

Lieutenant-Colonels G. P. Crowden and A. McG. Duff, M.C., from supernumerary for service with the O.T.C., to be Lieutenant-Colonels.

Major W. Barclay, M.C., from Territorial Army Reserve of Officers, R.A.M.C., to be Acting Lieutenant-Colonel.

Lieutenant L. W. Proger, from Territorial Army Reserve of Officers, R.A.M.C., to be Acting Lieutenant-Colonel and Officer Commanding, Army Blood Transfusion and Surgical Research Laboratory.

Major J. M. Smeaton, having attained the age limit, has relinquished his commission and retains his rank with permission to wear the prescribed uniform.

Major T. S. Torrance to be Deputy Assistant Director of Medical Services, 52nd (Lowland) Division.

Majors W. Brockbank, L. F. E. Jeffcoat, H. Wilson, M.C., N. H. H. Haskins, M.C., H. M. Morris, F. H. Scotson, A. C. M. Savege, T.D., C. B. Levick, J. H. Blackburn, M.C., C. W. Greenhill, H. K. Griffith, E. T. H. Lea, J. L. Menzies, M.C., H. H. Fowler, S. S. Greaves, D.S.O., M.C., A. M. Hughes, R. W. Fairbrother, A. M. Jones, G. V. Davies, J. G. Graham, and H. L. Sheehan, from Territorial Army Reserve of Officers, R.A.M.C., to be Majors.

Majors J. E. Fraser and W. Lamb, from supernumerary for service with the O.T.C., to be Majors.

To be Acting Majors and Deputy Assistant Directors of Medical Services as indicated in parentheses: Captain A. R. C. Higham (2nd London Division, T.A.), Captain F. N. N. Roberts (48th Division, T.A.), Captain F. R. Bettley (53rd Division, T.A.), Captain M. W. Gonin (54th Division, T.A.), Captain E. H. P. Smith (43rd (Wessex) Division), Captain M. L. Formby (1st London Division).

Captain G. D. Kersley to be Major.

Captains H. W. E. Dickey and J. S. Minett have resigned their commissions.

Captain R. J. McN. Love has relinquished his commission and retains his rank.

Captains C. Shaw-Crisp, F. J. Whitelaw, H. P. Gabb, M.C., B. B. Morgan, G. Chesney, L. F. O'Shaughnessy, C. C. Taffs, J. F. Ward, M. E. D. Roberts, W. R. Nash, A. C. Sinclair, C. E. Sykes, H. G. Dodd, F. A. Smorfitt, A. W. Uloth, M.C., A. N. Smith, J. G. Morrin, H. S. Allen, R. A. Quinn, and F. Evans, M.B.E., from Territorial Army Reserve of Officers, R.A.M.C., to be Captains.

To be Captains: F. E. Anderson, D. S. Macpherson, and J. R. Tibbles.

Captains N. Heath, W. M. Arnott, H. H. Kenshole, W. I. C. Morris, S. Andrews, I. Gordon, N. J. Logie, J. B. Forsyth, A. C. Frazer, R. W. Nevin, W. M. Nichols, and M. H. A. Davison, from supernumerary for service with the O.T.C., to be Captains.

Captain N. C. Oswald, from seconded list, to be Captain.

Lieutenants A. G. V. Aldridge, J. B. Plews, J. Mackay-Dick, and L. F. W. Salmon to be Captains.

Lieutenant E. J. G. Wallace has resigned his commission.

Lieutenant B. C. Curwood has resigned his commission on appointment to the Royal Air Force.

Second Lieutenant J L Taylor, from 6th Battalion Gordons, to be Lieutenant, with seniority January 18, 1939.

Lieutenant I. A R Mackenzie, from Gordons, to be Lieutenant

Lieutenant J. D. Easton, from supernumerary for service with the O.T.C., to be Lieutenant.

Lieutenant H. V. M. Jones has relinquished his commission on account of ill-health.

To be Lieutenants: G. R. Ford, C. M. MacQ. Murray, J. M. Moran, J. E. Morrish, R V. Harris, S. S. B. Gilder, O. E. Smith, W. L. Ogle, D Turner, G. Karstaedt, S. L. Frank, H. J. Seddon, R. L. Portway, L. H. Murray, G D. Falconer, C. P. B. Wells, R. Barraclough, P. J. B. Dyce, R T. Rushton, J. J. Davis, E J. Goldsmith, S. G. McK. Francis, K. Maccoll, J. M. L. Howat, A. Wailer, R. I. C. Bradford, J. F. Mackay, and W. J. Street

Lieutenants C. Stewart, B. McK. Dick, M. J. Bett, E. T. Colville, R. E. Pleasance, L. H. Crosskey, and A. C. Flemming, from Territorial Army Reserve of Officers, R A.M.C., to be Lieutenants.

Lieutenants (on probation) F. J. Ingham, C. E. Brown, E. P. Jowett, W. M. McLennan, R. H. C Manifold, J. A. Allen, and M. F. X. Slattery have been restored to the establishment.

TERRITORIAL ARMY RESERVE OF OFFICERS: ROYAL ARMY MEDICAL CORPS

Major C. D. S. Agassiz, M.C., has resigned his commission and retains his rank with permission to wear the prescribed uniform.

A, Simpson-Smith to be Major.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

To be Lieutenants: R. G. M. Keeling, K. M. Bell, A. W. G. Cumming, T. D. W. Fryer, L. Gore, G. Haddick, F. G. Holman, C. H. Kerr, A. H. Knowles, D. H. Mackay, A. R. Madden, L. E Milton, A. H. B. Rhodes, W. J. G. Barrie, B. Best, R. Bevan, J. Brennan, D. Brown, A. D. C. S. Cameron, V. Chadwick, A. F. Cowan, D. S. Cownie, C. B. Crofts, J W. N. Deurden, W. D. Dyson, W. R. Gavin, H. C. Kennedy, J H. Patterson, G. W. Pimblett, W. M. Priest, L G. Warwick, G. N. Wood, F. A. Prosser, F G. Greenwood, G. T. Lipscombe, S McCallum, D McIntosh, A. M. Maiden, K. D. G. Reid, R. Y. Stevenson, A. W. Taylor, W. G. Timmis, J. F. Varley, H. Walton, R. B. Wright, D. E H. Beattie, A. K. Cosgrave, W. E. Dornan, R. A. Grant, W. Geraghty, J. M. Harker, R. G. Main, A. B. Milligan, J. G. B. Platts, H. J. Crogan, J. Devlin, H. Rinn, J. R. Bradshaw, C. N. Brown, O. I. Green, A. J. Hardy, W. A. Carey, W. R. Grant, G. B. Marsden, J. M. Bailey, F. Widlake, W. d'A. Maycock, S. J. Chesser, W. Ferguson, I. Richmond, F. G. Jones, A. Kekwick, J. G. Scott, B. W. Lacey, P. R. Greeves, A M. Wadsworth, C. G. Baker, J. C. Dick, B. O'Carroll, G. M. Coope, G. H. W. Kentes, W. Foxe, A. M Graham, S. C. Buck, E. Farquharson, P. U. Colyer, M. O'C. Drury, K. Fraser, R. Baker, A. H. Cooke, C. F. C. White, N. A. Buxton, P. A. Forsyth, J. B. Joyce, L. Wailer, J. C. Walker, G. A. Wray, F. E. Cayley, H. C. Duffey, K. MacD. Foster, E. H. S. Bebb, C. M. Friedland, C. A. Hutt, J. D. James, L. H. Wilkinson, K. D. Gibson, J. J. N. Daniels, G. R. Sedleigh-Denfield, G. D Gordon, T. Sutton-Coulson, J. J. Geany, A. H. Gurney, E. M. G. Galton, W. N. Douglas, A. B. Hewlett, H. G. Hind, A. J. Ireland, J. McHaffie, W. W. Roberts, C. L. Taylor, B. Reeves, C. R. Hillis, R. T. Wimmer, A. G. Chamberlain, F. C. Haward, H. H. Jacob, T. Neville, A. J. S. De Freitas, A. J. Rouse, F. W. Linton-Bogle, W. G. P. Dyson, A. M Gardner, W. F. Hamilton, E. K. Hole, A. Rothwell, R. T. Sharp, J. B Ro't, J. R. Salmond, W. W. Weir, G. McComas, J. E. V. Jones, P. H. Lenton, D. W. Lindsay, J. P. Semple, A. E. W. Brooker, R. N H. Williams, B. W. Hughes, D M. Jones, S. Bennett, J. W. Spence, J. H. L. Conway-Hughes, N. H. Halper, N. J. S Gurney, J. J. Kempton, S. M. Vassallo, C. K. Carroll, R. Kauntze, C. W. Seward, K. H. Taylor, T. W. Buckley, A Colbert, J. N. Hamill, C. W. Illife, A. K. Kerr, W. A. H. Stevenson, T. M. Strang, J. M. Young, A. I. Barron, K. Simon, W. D. L. Smith, R K Pilcher, H. Pozner, M. T. Read, and J. C. Townley.

Postgraduate News

The Fellowship of Medicine announces that a course in neurology, especially intended for M.R.C.P. candidates, will be given at the West End Hospital for Nervous Diseases, daily at 2.30 p.m., from November 13 to 24. Instruction will consist of a clinical demonstration followed by a lecture. It is hoped that further short courses of instruction may be arranged in the near future, and postgraduates desiring instruction are asked to make known their requirements to the Fellowship of Medicine, 1, Wimpole Street, W.1.

WEEKLY POSTGRADUATE DIARY

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane Road, W.—*Daily*, 10 a.m. to 4 p.m., Medical Clinics, Surgical Clinics and Operations, Obstetrical and Gynaecological Clinics and Operations. *Daily*, 1.30 to 2 p.m., Post-mortem Demonstration. *Mon.*, 4 p.m., Lord Horder, Ward Clinic. *Wed.*, 11.30 a.m., Clinical-Pathological Conference (Medical): 2.30 p.m., Clinical-Pathological Conference (Surgical). *Thurs.*, 2 p.m., Dr. Duncan White, Radiological Conference. *Fri.*, 2 p.m., Clinical-Pathological Conference (Gynaecological).

NOVEMBER

8 Wed. Central Emergency Standing Subcommittee, 2 p.m.

Katherine Bishop Harman Prize

The Council of the British Medical Association is prepared to consider an award of the Katherine Bishop Harman Prize, of the value of £70, in the year 1940. The purpose of the prize, founded in 1926, is the encouragement of study and research directed to the diminution and avoidance of the risks to health and life that are apt to arise in pregnancy and child-bearing. It will be awarded for the best essay submitted in open competition, competitors being left free to select the work they wish to present, provided this falls within the scope of the prize. Any medical practitioner registered in the British Empire is eligible to compete. Should the Council of the Association decide that no essay submitted is of sufficient merit the prize will not be awarded in 1940, but will be offered again in the year next following this decision, and in this event the money value of the prize on the occasion in question shall be such proportion of the accumulated income as the Council shall determine. The decision of the Council will be final.

Each essay must be typewritten or printed in the English language, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address. Essays must be forwarded so as to reach the Secretary, to whom all inquiries should be addressed, British Medical Association House, Tavistock Square, London, W.C.1, not later than December 31, 1939.

Important Notice concerning Appointments

The attention of medical practitioners is drawn to the important notice concerning appointments which is published each week in the advertisement columns of the *Journal*. This notice asks practitioners to communicate with the Secretary of the British Medical Association before applying for any of the appointments listed therein. It appears this week at page 43.

VACANCIES

EXAMINING FACTORY SURGEONS.—The following vacant appointments are announced: (*a*) Islay (Argyllshire); (*b*) Mevagissey (Cornwall); (*c*) Cranborne (Dorset); (*d*) Selston (Nottinghamshire). Applications to the Chief Inspector of Factories, Home Office, Whitehall, S.W.1, for (*a*) by November 7, and for (*b*), (*c*), and (*d*) by November 14.

SPECIALIST MEDICAL REFEREE UNDER THE WORKMEN'S COMPENSATION ACT, 1925, to take ophthalmic cases arising in the County Court Districts of Birmingham (Circuit No. 21): Bromsgrove, Bromyard, Kidderminster, Stourbridge, Tenbury, Worcester, Evesham, Great Malvern, Hay, Hereford, Ledbury, Leominster, Kington (Circuit No. 22); Atherstone, Coventry, Bletchley and Leighton Buzzard, Northampton, Daventry, Rugby, Nuneaton (Circuit No 23); Aylesbury, High Wycombe, Banbury, Shipston-on-Stour, Buckingham, Chipping Norton, Oxford, Thame, Wallingford, Wantage, Witney, Henley-on-Thames, Windsor, Reading (Circuit No. 36). Applications to the Private Secretary, Home Office, Whitehall, S.W.1, by November 18.

APPOINTMENTS

EXAMINING FACTORY SURGEONS.—T. S Blaiklock, M.D., for the Morpeth District (Northumberland); A. N. Bousfield, M.B., B.S., for the Wooler District (Northumberland); A. H. MacG. McMullan, M.B., B.S., for the Shipston-on-Stour District (Warwickshire); P. S. Byrne, M.B., Ch.B., for the Carnforth District (Lancashire).

The Minister of Health has appointed Miss E. M. R. Russell-Smith and Miss E. A. Sharp to be assistant secretaries (acting) of the Ministry of Health.

WAR NOTICES

Notification of Measles and Whooping-cough

At the last meeting of the Council of the British Medical Association, held on September 27, it was reported that the Ministry of Health proposed to make the notification of measles and whooping-cough compulsory during the present emergency and suggested that a notification fee of 1s. instead of 2s. 6d. should be paid to practitioners. The following resolution was passed:

> *Resolved:* That the Ministry of Health be informed that the Council of the Association does not see its way to accept the proposal that the prescribed fee for the notification of measles and whooping-cough should be 1s. per case instead of 2s. 6d.

Despite this protest the Ministry has adhered to its original proposal to reduce the fee for notification of these two infectious diseases to 1s. The matter will be further considered by the Association's Executive Committee at an early date.

Emergency Medical Service: Deputation to Minister of Health

At a meeting on November 3 the Minister of Health, Dr. Walter Elliot, who was accompanied by Sir George Chrystal, Permanent Secretary of the Ministry, and Dr. Hebb, Director-General of the Emergency Medical Service, discussed with representatives of the advisory committee set up by the Central Emergency Committee (Central Medical War Committee) their recommendations for the reorganization of the Emergency Medical Service. The main objects of these recommendations were to release consultants and other senior members of the medical profession from their whole-time obligations in the Emergency Medical Service so that they might be free to attend to the needs of the civilian sick and to their normal duties in the medical schools, while remaining available on a part-time basis for casualty work. The committee's representatives were introduced by Mr. H. S. Souttar, chairman of the Central Medical War Committee, and consisted of Sir Robert Hutchison, P.R.C.P. (chairman of the Advisory Committee), Mr. Hugh Lett, P.R.C.S., Professor William Fletcher Shaw, P.R.C.O.G., Sir Girling Ball, Professor A. H. Burgess, Professor R. M. F. Picken, Dr. G. C. Anderson (Secretary), Dr. Charles Hill (Deputy Secretary).

The Minister discussed their recommendations point by point, and said that now that he had in his mind the broad principles of their proposals he would consider them with his expert advisers. He hoped that it would be possible for a few representatives of the committee to discuss the details of the proposals with his advisers next week.

CENTRAL EMERGENCY COMMITTEE
(Central Medical War Committee),
British Medical Association House,
Tavistock Square, W.C.1.

THE SHARE OF THE ABSENTEE PARTNER

A number of the inquiries that are being received by the B.M.A. relate to the way in which the moneys received by a partnership under the Protection of Practices Scheme should be divided between the individual partners. While there may be, in any particular case, factors which would modify any decision—as, for instance, where the partners' lists of insured persons varied widely in size—the general principles of the scheme offer a valuable guide as to how the moneys may be apportioned. To take a typical case, Dr. A. will receive as an absentee half of his panel cheque from the insurance committee, while Dr. B., by claiming on the "emergency pool," receives a payment approximating to the other half. This division of these moneys can be regarded as equitable, as it is very much the same as the way in which moneys are divided between two practitioners not in partnership.

At first sight it might be thought that the apportionment of the other receipts of the partnership should be dealt with in a similar manner—that is, that each of the partners would receive a share similar to what he would have obtained had they been single-handed practitioners and not in partnership. There are, however, two considerations which must be taken into account before a fair and equitable method of division of the receipts can be arrived at. Were Dr. A. and Dr. B single-handed practitioners it is unlikely that Dr. B. would undertake to see the whole of Dr. A.'s patients, unless both practices were comparatively small. If the work proved to be considerable, Dr. B. would probably limit the number of patients he saw, and induce other patients of Dr. A. to find some other doctor in the neighbourhood. Where, on the other hand, Dr. B. is a partner of Dr. A., it is unlikely that he would wish patients of the practice to have to seek advice elsewhere; he would either do a considerable amount of extra work himself or might possibly need to engage an assistant to help him out. That is to say, instead of Dr. A.'s patients constituting an increase of, say, 20 per cent. to the work of other doctors, which would be undertaken without inconvenience, they would constitute an increase of possibly 100 per cent. to Dr. B.'s work. The second consideration is that were Dr. B. a single-handed practitioner he would be compensated for any extra work by the fact that he was getting in touch with new patients in the area, who would otherwise have become patients of Dr. A. In a partnership, however, Dr. A. on returning to practice expects to resume his share of the joint practice, which has been maintained at a high level by Dr. B.'s efforts; that is to say, the prospects to which he returns are enhanced in value as compared with those which may be expected by a single-handed practitioner.

It is suggested that the following is a method of dividing receipts from private practice which would take into consideration all these points. The total expenses of running the practice would be deducted from the total receipts, and the net income would then be divided between the partners according to their shares under the partnership agreement. The partner or partners who are absentees would agree that, in consideration of the fact that they were absent on National Service, they would expect only 50 per cent. of their share arrived at in this manner, and that the other 50 per cent. should be retained by the remaining partner or partners in consideration of the work they had done in maintaining the present income and the future standing of the practice. Each absentee would retain his Army salary, which would not come into these calculations at all.

Corrigendum

In the war notices on the Emergency Medical Service in the *Supplement* of November 4 (p. 215) it was stated that comparatively few of the 3,000 practitioners in the provinces were enrolled "on a part-time basis." This should have read "on a whole-time basis."

Correspondence

Organization and Staffing of First-aid Posts

SIR,—It is one of the ironies of fate that efforts directed to some end occasionally have the opposite effect in practice, and this seems to be happening to A.R.P. in certain localities. Thus in order to effect co-ordination of the various ambulance services all their personnel have naturally been placed under the authority of the local authority, which means in practice the medical officer of health. Unfortunately, this tends to break the attachment which has naturally grown up between the ambulance divisions and their own surgeons; one loyalty is broken before another has had time to take its place, and the result is a feeling of being driven instead of led.

Then it is quite obvious that the medical officer of a first-aid post must have the personnel under his immediate charge, and this has the unfortunate effect of making a distinction between those under the charge of the medical officer of health and those at the first-aid post. This is felt by the personnel, and it also has deplorable results in practice. Stretcher parties are under the control of the medical officer of health through the control room, and every first-aid post has a great preponderance of women on its staff; mine, for example, has a complement of thirty women and six men. Of these latter two are required to control those who may come to the post, and any who may be left over—for we are supposed to arrange for three shifts—may be more than occupied with decontamination if gas has been used. This leaves the women to do practically all the first-aid work proper, male and female. Now it would seem a sensible arrangement that as soon as a raid is over and the stretcher parties have returned they should be available to do anything necessary inside the post. But as they are under the control of the medical officer of health it is definitely ruled that this cannot be done.

Other examples might be given in which too close adherence to regulations may and does cause irritation and inefficiency sufficient to damp the enthusiasm of the most ardent. The fundamental trouble seems to be that public servants have become officials and forgotten that they should be servants of the public, while the regulations have been drawn too strictly in some directions with a misapprehension of actual conditions in others. For example, Circular 1831, para. 3, states that the medical officer of the first-aid post "will be responsible to the medical officer of health, who will no doubt confer with the medical officers . . . for the purpose of instructing them, etc." We are all anxious to learn, but in most cases the medical officers to the posts have been doing first-aid work for years—often in actual war conditions—while the medical officer of health has not. The latter, therefore, does not confer over this or anything else either. If the regulations had insisted on co-operation as the first essential all might have been well, but instead they emphasize the primacy of the medical officer of health. Medical officers of health should give practitioners in their area not authority, for which few of us wish, but that co-operation without which the best of schemes must fail, and that consideration which is the foundation of all voluntary effort and healthy local activity.—I am, etc.,

Winsford, Oct. 28. **W. N. LEAK, M.D.**

Naval, Military, and Air Force Appointments

ROYAL NAVAL MEDICAL SERVICE

Surgeon Commander R. Buddle, O.B.E., has been placed on the retired list with the rank of Surgeon Captain.

ROYAL NAVAL VOLUNTEER RESERVE

To be Surgeon Lieutenant Commanders: W. Watkinson, V. M. Matthews, and J. A. Lewis.

Surgeon Lieutenants E. A. H. Hindlaugh and M. G. Stratford to be Surgeon Lieutenant Commanders

Probationary Surgeon Lieutenant D. J. N. McNab to be Surgeon Lieutenant, with seniority December 28, 1937

To be Temporary Surgeon Lieutenants: H. V. Lavelle, L. R. Blair, A. J. Lea, T. O. Mason, D. V. John, S. P. H. Fergus, R. G. Knight, T. Parker, F. G. Maitland, W. A. Robson, J. D. Thompson, A. L. Lancaster, C. R. Gibson, F. T. Doleman, G. E. Lewis, T. I. V. Ferguson, L. G. Boyd, J. E. Struthers, E. J. Neill, J. D. Hughes, J. F. A. Hackett, the Hon. A. G. Gathorne Hardy, E. M. Donaldson, J. F. Ryan, M. Curwen, W. T. Andrews, A. L. Schofield, J. D. Kinnear, W. B. D. Miller, E. Ashman, E. W. Darrell, M. Mandelstam, A. McW. Green, S. L. Lord, A. D. Hoffmann, K. C. Jeffery, and A. J. D. Lewis.

ARMY MEDICAL SERVICES

Lieutenant-Colonel R. E. Barnsley, M.C., from R.A.M.C., to be Colonel.

ROYAL ARMY MEDICAL CORPS

Majors E. L. F. Nash, M.C., and M. Morris to be Lieutenant-Colonels

Lieutenants (on probation) G. P. Crean and J. D. Condon have been confirmed in their rank.

ROYAL AIR FORCE MEDICAL SERVICE

Air Vice-Marshals Sir John McIntyre K.B.E., C.B., M.C., and Sir Alfred W. Iredell, K.B.E., C.B., have relinquished at their own request, their present rank while re-employed with the Royal Air Force and have been granted the rank of Group Captain

ROYAL AIR FORCE RESERVE OF OFFICERS: MEDICAL BRANCH

R. A. W. Kerr has been granted a commission in Class D as Flight Lieutenant with seniority October 17, 1934

WEEKLY POSTGRADUATE DIARY

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane Road, W.—*Daily*, 10 a.m. to 4 p.m., Medical Clinics, Surgical Clinics and Operations, Obstetrical and Gynaecological Clinics and Operations. *Daily*, 1.30 to 2 p.m., Post-mortem Demonstration. *Mon.*, 3.30 p.m., Lord Horder, Ward Clinic. *Wed.*, 11.30 a.m., Clinico-Pathological Conference (Medical); 2.30 p.m., Clinico-Pathological Conference (Surgical) *Thurs.*, 2 to 4 p.m., Dr. Duncan White, Radiological Conference. *Fri.*, 2 p.m., Clinico-Pathological Conference (Gynaecological).

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

Section of Psychiatry.—Tues., 2.15 p.m. Meeting in honour of the late Professor Sigmund Freud. Short addresses will be given by Dr Ernest Jones, Professor E. Mapother, and Professor Millais Culpin.

Section of Physical Medicine.—Fri., 2.30 p.m. Presidential Address by Dr. J. B. Mennell: Foot-gear.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W.—*Thurs.*, 3 p.m., David Lloyd Roberts Lecture by Sir Robert Hutchison, Bt., P.R.C.P.: Medical Literature.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 26, Portland Place, W.—*Thurs.*, 4 p.m. Paper by Professor P. A. Buxton: The Louse: Present Knowledge and Future Work.

VACANCIES

EXAMINING FACTORY SURGEON.—The appointment at Littlehampton (Sussex) is vacant. Applications to the Chief Inspector of Factories, Home Office, Whitehall, S.W.1, by November 21

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this heading is 9s. This amount should be forwarded with the notice, authenticated by the name and address of the sender, and should reach the Advertisement Manager not later than the first post Tuesday morning to ensure insertion in the current issue.

DEATH

CAMPBELL.—On November 3, 1939, L. Mabel R. Campbell, M.A., M.B., Ch.B., of 2 Park Terrace, Newcastle-on-Tyne, daughter of the late Rev. John Campbell, D.D., Kirkcaldy, Fife

WAR NOTICES

Recognition of Previous R.A.M.C. Service

Following representations by the Central Emergency Committee, the War Office has decided that practitioners who have had previous war service in the Royal Army Medical Corps will, if now appointed to emergency commissions in the Corps, be gazetted in the rank of captain from the date of joining. This ruling will apply to those practitioners who have already been given emergency commissions as well as to those who are appointed to emergency commissions in the future.

Petrol Rationing

Much difficulty has been caused by the failure on the part of large numbers of medical practitioners to follow the proper procedure when applying for supplementary petrol rations. It is again emphasized that every such application must be made on Form R.M.S.1, and must be accompanied by the car registration book.

Now that the Divisional Petroleum Officers have had time to organize their work there is reason to hope that many of the mistakes and misunderstandings which occurred at the time of the first allocation of petrol rations will in future be avoided. The British Medical Association remains in touch with the Petroleum Department and will do everything possible to ensure that medical applications are dealt with reasonably and promptly. It is recommended that the word "Doctor" be written on the envelope containing the application.

Members are reminded that complaints and appeals should be addressed to the Divisional Petroleum Officer and *not* to the Association's local advisory officer.

Central Emergency Committee
(Central Medical War Committee),
British Medical Association House,
Tavistock Square, W.C.1.

MEDICAL STUDENTS AND MILITARY SERVICE

Although the problems confronting medical students at this time are not primarily the concern of the British Medical Association, inquiries received suggest that the following information will be of interest to some members.

A medical student who has passed the first professional examination and completed two terms of anatomy and physiology is a member of a "reserved" occupation. He is expected to continue his studies and is not liable for military service or eligible for national service of other kinds. If the necessity for maintaining himself away from home, resulting from the transference of his medical school to another area, causes financial difficulty, no State assistance is available to him. On this problem, as on any other difficulties with which he may be confronted, he should consult the dean of the school.

A student who has not yet passed the first professional examination and completed two terms of anatomy and physiology is at liberty to continue his studies unless and until he is called up for military service, provided that in the changed conditions his medical school can continue to provide a vacancy for him. In the event of his completing the stated period of anatomy and physiology before his age group is called up he will cease to be liable for military service and will be treated as "reserved."

No decision has yet been reached regarding the release from military service of medical students who have reached a stage of the curriculum at which they would ordinarily be regarded as "reserved" but who, because of their pre-war commitments to the Territorial Army or other branches of the Forces, are now serving as combatant officers or in the ranks. It is understood that the Ministry of Health is in communication with the military authorities on this subject.

CANADIAN MEDICAL ASSOCIATION AND THE WAR

We quote below from an editorial entitled "War" which appeared in the *Canadian Medical Association Journal* for October, 1939.

"The Canadian Medical Association has not been remiss in its duty. Months ago it took action to aid the Federal authorities in certain important directions and at all times has manifested its readiness to do its bit. It will continue its efforts. As illustrating its attitude we cite the following message which was sent on September 1 to the Right Honourable the Premier of Canada, the Honourable Minister of Defense, and the Honourable Minister of Pensions and National Health:

> 'In this time of crisis I am directed to say that the Canadian Medical Association with its Divisions and Branches across Canada stands ready to perform such services as may be regarded as properly coming within its scope. In the event of war the medical needs of the army and of the civilian population give rise to problems of medical selection in order that both needs may be met adequately. In the Motherland the British Medical Association has undertaken to act in an advisory capacity to the Government in the solution of these problems. Should the Government of Canada desire the Canadian Medical Association to act in a similar advisory capacity may I repeat that the Canadian Medical Association is ready and willing to do so.
>
> (Signed) T. C. Routley,
> *General Secretary,*
> *Canadian Medical Association*'

Most of us remember with pride the noble response made by the medical men of this and other countries during the last emergency, twenty-five years ago. The sacrifices made then were made willingly. We do not doubt that they will be made willingly again. It is a relief to know that we are now better prepared. The lessons of the last war have been well learned. There will be no attempts to fit square pegs into round holes. We are satisfied that the medical men will be assigned to the duties which each is best qualified to perform. This is reassuring. It will make for greater efficiency. Let us get on with the job."

PROTECTION OF PRACTICES

HOW THE SCHEMES WORK

Throughout the country the profession is co-operating loyally to secure the smooth working of the local Protection of Practices Scheme. In many areas the percentage of practitioners who have entered into an agreement with the Local Emergency Committee is a very high one. The result has been to make simpler the administration of the scheme by the committee and by those other organizations concerned such as insurance committees and local bureaux.

The ordinary provisions of the model scheme involve the acting practitioner signing the medical card of those patients of the absentee doctor who apply for treatment and sending the cards to the insurance committee. In this way the acting practitioner builds up a "provisional list," on the basis of which he is remunerated at the end of the quarter. The small number of patients who obtain treatment in the early stages of the scheme, as compared with the total number of patients "at risk" because their doctor is an absentee, is compensated for by the fact that the unit value of each claim made on the "emergency pool" in this way is a comparatively large one to begin with, diminishing in subsequent quarters as more patients receive treatment. As regards private patients, the acting practitioner records the particulars of any treatment given on the cards provided. These cards are sent each month to the bureau, which arranges the division of fees between the practitioners concerned.

This being the way in which the scheme deals with the single-handed absentee practitioner, it is interesting to see how adequately these arrangements can cope with conditions in a partnership practice. The following observations apply to schemes based on the model—that is, to schemes in which no special provision is made for partners or others acting as "nominated deputies." They do not apply to those few schemes in which such special provision is made. To take an illustrative case, Dr. A. and Dr. B. are in partnership with equal shares; the practice is not an unduly large one and neither partner is working to capacity. Dr. A. is called up on National Service, becoming an absentee practitioner: Dr. B. is left behind as an acting practitioner. As regards national health insurance work, Dr. B. proceeds in the same way as any other acting practitioner. He signs the medical card of any N.H.I. patient seeking advice if the patient is on any other practitioner's panel list, *including patients of the partnership who are on his partner's list*, and sends all such signed medical cards in to the insurance committee. It has been objected to this procedure that it entails extra work for the acting partner, and that in normal times patients of a partnership are seldom asked to produce their medical cards. The notices exhibited in the practitioner's surgery and waiting-room should make patients realize that their co-operation is necessary at the present time if doctors are to be able to continue to provide medical attention for all who require it, and that the production by patients of their medical cards when required is one of several ways in which they can assist in these emergency arrangements. The slight amount of extra-work in which the remaining partner or partners are involved is worth while if it secures uniformity in the central arrangements of the scheme, for any such simplification must be of benefit to all practices in the area, including that of the partnership.

By proceeding on these lines Dr. B. institutes claims on the emergency pool, to which Dr. A. has contributed half his usual panel remuneration. Under the usual conditions in a partnership practice Dr. B. is likely to see the bulk of Dr. A.'s panel patients, and his claim on the emergency pool is likely to be a substantial one. In this way he will be adequately remunerated for all the patients of Dr. A. whom he actually sees, while at the same time any other acting practitioners who have to see some of Dr. A.'s patients realize that they also will be adequately remunerated as a result of Dr. A. having made the usual contribution to the pool.

With regard to private patients of a partnership some slight modification of the normal arrangements is desirable. Where Dr. B. knows, or has ascertained, that the patient is one of Dr. A.'s private patients, records of professional services need not be sent on Form A to the bureau. The book-keeping necessary in such cases would be done under the ordinary arrangements of the partnership. It will be seen that this modification of the usual arrangements of the scheme makes for simplification and economy, and cannot adversely affect the interests of other practitioners in the area. Where, however, Dr. B. is called to give advice to patients of other absentee practitioners, he fills up Forms A and AA and sends them on to the bureau in the usual way.

ORGANIZED TEACHING OF MOTHERCRAFT

The National Association of Maternity and Child Welfare Centres recently called a meeting of medical men and women to consider the establishment of a scheme of instruction and examination in mothercraft with a view to ensuring that girls who will be the mothers of the next generation are better equipped than at present in this respect. A certain amount of teaching of mothercraft is given in the elementary and secondary schools, but it is merged with many other domestic subjects which perhaps make more appeal to the girl mind. It also figures in the syllabus of the evening institutes, but there again it has not proved to be a popular subject. A certain amount of such teaching, of course, is given to expectant mothers at the ante-natal centres, but the association thinks that this teaching should begin earlier, even before marriage. The association, therefore, has drawn up regulations and a syllabus for the teaching of mothercraft, and these are being brought to the attention of local education and public health committees. It is proposed to have a system of examinations of a non-professional type for women and girls over 16 who have attended an approved course of instruction. The examiners, appointed by the association, would work in pairs, one doctor and one health visitor examining candidates together. Each candidate passing the examination would be given an appropriate certificate. The full course of instruction would comprise not fewer than twenty-four lectures, each lasting one hour, and followed by one hour's practical work. The lecturers would be doctors, nurses, health visitors, and other persons of special experience, chosen locally and remunerated according to a local arrangement. As for the examiners, their fees would be based on the number of candidates, the minimum being £2 2s. for doctors and £1 1s. for health visitors, and it is suggested that the examination of twelve candidates would normally occupy the time of the pair of examiners for a two-hours session. It is also proposed to make available a junior course for younger girls, which would be followed by an examination and the award of a junior certificate. The senior syllabus is comprehensive. It begins with simple anatomy and physiology and passes on to the care and diet of the expectant mother, the necessity for early medical examination and continued supervision, and the arrangements for home or hospital confinement. Then come the care of the mother during the lying-in period, the importance of awareness regarding sepsis, the early management of the infant, breast and artificial feeding, weaning, and normal development and character formation. One section deals with the prevention of disease—how to avoid digestive upsets, infections, and injuries, how to practise efficient home nursing, and the necessity for periodical overhaul by the doctor. What seems likely to be a very useful section is headed "Popular errors and fads." Finally the student will be instructed how to make the best use of the provision afforded by local authorities for mother and child. The junior course deals with elementary facts about infants and the feeding and clothing of both infants and older children. The association has issued some excellent pamphlets on the whole subject, one of which, addressed "To Mothers and Fathers," has reached a circulation of 1,100,000 copies.

MIDWIFERY SERVICE

The report of the Central Midwives Board for the year ended March 31, 1939 (H.M. Stationery Office, price 4d.), shows that 16,761 women were practising as midwives in England and Wales in 1938, compared with 17,494 in 1937, and that there were 62,905 women on the Midwives Roll, a net decrease of 4,184 on the total at the end of March, 1938. During the year the new training and examination rules of the Board came into operation, and the number of candidates entering for examination was the largest on record—4,806 as against 4,420 for the previous year and 2,683 for the year ended March 31, 1927.

A report on the examinations held during the year is included, and notes of various decisions by the Board on midwives' training, etiquette, and practice. Reference is also made to the post-certificate courses of training for midwives which were made obligatory as from January 1, 1939. The report also refers to the arrangements which had been made before the end of March this year for an efficient midwifery service in war time. The Board had compiled a register of women whose names were on the current Roll of Midwives and who would be free and willing to undertake midwifery work either in their home districts or anywhere in the country. It was divided into two parts: the first contained the names and particulars of those midwives who were prepared to act only in their home districts, and was arranged according to the respective local supervising authorities; the second part related to those midwives who were prepared to work anywhere in the country. On the outbreak of war a duplicate of the first part of the register was distributed to the various local supervising authorities. The second part constitutes a central pool which can be drawn upon as required on application to the Board by any local authority whose need for additional midwives remains unsatisfied.

Assurance for Doctors

War Risks and Permanent Disability Insurance

A policy recently issued by one of the large insurance companies undoubtedly supplied to some extent a long-felt public want—namely, cover against death and permanent disablement by loss of limbs or sight. The drawback to such a contract, however, is its limitation in respect of permanent disability, since payment is conditional on loss of limbs or of sight. A policy of this nature to be really satisfactory should cover those cases in which the individual is permanently precluded from following his normal employment by war injury in one form or another but in which there is no actual loss of limbs or sight. It should also cover permanent disability arising from the use of poisonous gases.

Such a policy has just been placed on the market. It is subscribed by a leading group of underwriters at Lloyds, and the premium at present is moderate. The contract insures a capital sum which is paid upon the individual being rendered permanently incapable of following his *normal* employment, and such incapacity must have lasted one year from the date of the injury before payment is made. The decision whether "permanent incapacity" exists rests with two medical men, one appointed by underwriters and one by the policy-holder, and, should they disagree, with a third medical referee selected jointly by both parties at the outset. The premium required for the contract, which is limited to war injuries received in the United Kingdom only, is 10s. per cent. per annum. Underwriters reserve the right to increase or decrease the rate at each renewal as they think fit.

It is, of course, essential to provide an adequate sum insured, because apart from private means and the sale value of a practice that sum will have to earn the necessary income for the rest of the insured person's life. It should be remembered that this policy covers only permanent disability and not the risk of death, which can easily be provided for under other forms of policy. The Medical Insurance Agency is in a position to supply full details of the scheme and give any essential advice.

Correspondence

Unwanted Doctors

SIR,—I am becoming increasingly perturbed with the ungenerous way the authorities are dealing with a section of the profession. Over a year ago the majority of us were willing to serve the country either in a military or civilian capacity. This was confirmed last March. Now after two months of war a fair proportion of us find we are not wanted for the military or civilian services and only to a limited extent for private practice. I believe only surgeons, radiologists, pathologists, and anaesthetists are in most demand for the E.M.S. Few ophthalmologists are wanted for the E.M. and military services, and other specialists are similarly placed. Surely our services ought to be utilized in any emergency?

We ought to be rescued from this ambiguous situation. If we are not wanted for our specialty we ought to be told so. We ought to be given facilities immediately to get the necessary training to do something useful instead of being left as so much flotsam and jetsam. Moreover, it is evident every medical practitioner and qualified nurse should be provided with a steel helmet and service respirator and efficient shelter. Our services are too valuable to the community to be lost.—I am, etc.,

London, W.1, Nov. 4. CHARLES YOW, M.D.

A Warning to Others

SIR,—I feel it my duty to draw the attention of members of the British Medical Association to an unpleasant attempt at exploitation of the national emergency by an insurance company. I was previously in general practice, but was commissioned in the Royal Air Force (Medical Branch) on the outbreak of hostilities. A few weeks later I received a letter from a well-known company, with which I had insured my car, informing me that as a result of entering His Majesty's Service they were raising the premium on my car and at the same time reducing the benefit from its present full comprehensive scale.

I wrote to the company and explained that the car would only be used in this country and for the same purposes as previously—professional use and pleasure. I also said that there was no clause in the policy covering such an action on their part. In two subsequent letters they alleged that I had changed my occupation from that given in the proposal of medical practitioner. If those of us who take any active part in the present war are to lose their status as medical practitioners a large proportion of your members will be affected sooner or later.

With the object of settling our rights by means of a test case, I informed the company that I refused their demands and was prepared to fight the matter. I have to-day received a letter from the company in which the original policy is returned to me unchanged, the company asserting that their demands are still in order but that further correspondence is not justified. In other words, the company have surrendered completely in the face of an offer to go to law. I bring this to your notice so that other practitioners may know that the ramp has only to be fought in order to collapse. I enclose my card.—I am, etc.,

Nov. 6. FLYING OFFICER, R.A.F.

Car Labels

SIR,—Is it really the policy of the B.M.A. that the "Doctor" label should be affixed permanently to our cars? Surely it is intended for use during an actual emergency (air raid), not as a mobile daily advertisement. I have mounted mine on cardboard, and with elastic bands attached it to the small sun visor, which flaps down at once if the need should arise. I may be old-fashioned, but still prefer to think I belong to a profession and not a trade.—I am, etc.,

Nov. 7. M.B.

Naval, Military, and Air Force Appointments

ARMY MEDICAL SERVICES

Colonel A. G. Wells, D.S.O., late R.A.M.C., has retired and has been retained in his appointment.

Colonel J. S. Hughes, M.C., has retired on retired pay and has been granted the honorary rank of Brigadier.

Lieutenant-Colonel J. B. A. Wigmore, from R.A.M.C., to be Colonel, with seniority July 28, 1937.

ROYAL ARMY MEDICAL CORPS

Major W. S. Evans to be Lieutenant-Colonel.

To be Lieutenants: S. A. Bower, T. J. Guinan, W. Maxwell, H. L. Beale, R. C. Little, F. A. Bearn, B. P. R. Hartley, D. S. Piper, S. D. H. D. Wallis, J. C. Miller, E. J. Walsham, L. G. McLean, F. M. Hanna, G. Patton, M. T. O'Sullivan, H. McL. McLaren, C. D. Anderson, A. M. MacCallum, L. N. O'Hara, R. G. Melrose, F. O. Mell, A. U. MacKinnon, A. L. Masterton, W. E. Pennington, G. S. Trower, F. C. Hamilton, M. J. Hilton, D. C. Harris, J. A. Morton, R. T. Bannister, J. G. Macarthur, D. P. Pick, A. F. Stallard, V. R. O'Connor, D. J. Fraser, W. G. Brookes, A. H. G. Down, G. A. J. Teasdale, J. R. Kingdon, A. Roy, E. O. Watson, C. T. Norris, L. J. Panting, S. T. Williamson, J. G. Bogle, C. Rigby, J. M. McKillop, S. O. Aylett, T. J. McCarthy, J. Smallpeice, J. R. Steen, B. Yuill, H. P. Watts, A. Keay, H. H. Boyden, W. R. Hunter, J. J. Tillie, F. W. Dickson, J. M. Mitchell, T. I. Sibbald, G. de N. U. Somers, A. W. Forrest, J. A. Hartley, R. D. Monteith, D. R. Holden, D. Kelly, W. J. Bold, H. M. Boston, D. B. Smth, H. L. Wallace, H Simmons, J. G Jamieson, F. A. Donnolly, A. A. F. Shepherd, W. O. Warrington, J. C. Taylor, J. Marshall, M. T. Parker, A. S. Rudd, T. D. Inch, H. E. S. Stiven, W. B. Williams, A. F. R. Dewar, W. M. Forster, J. Amos, J. Brown, W. J. C. Crisp, E. H. Griffiths, H. G. H. Richards, C. T. H. Whiteside, J. Littlejohn, J. H. D. Millar, F. H. Barber, G. K. Beatty, P. Coleman, G. E. Ord, H. G. Stanton, J. M. Lawrie, A. Logan, H. Paterson, D. B. Wallis, H. P. Williams, D. Harkins, J. A. McEwan, D. Benson, R. P. Dinley, A. V. Griffiths, J. A. Neylon, G. G. Waldin, N. C. Coombs, N. W. Jones, A. E. Brewer, N. J. H. Davidson, H. K. B. Armstrong, R. J E. Bell, J. W. Browne, W. M. Burgess, A. E. Delgado, A. G. Lumsden, K. S. E. Macrae, H. J. Minford, E. A. E Palmer, R. H. Reid, C. A. Hinds-Howell, E. J. M. Wenyon, C F. Coutts-Wood, E. R. Woodroofe, P. M. Wright, A. D. Harper, G. M. Killpack, E. W. Skipper, J. L. Dales, W. M. Capper, D. H. Craig, P. A. Flood, F. S. Tait, A. Young, A. Burness, R. W. Cope, W. W. Deane, A. R. Dearlove, P. R. K. Lane, J. J. Hogan, A. J. Thomson, H E. Lewis, C. S. Wise, A. N. Redfern, A. D Fisk, F. Clifton, A. G. H. Clay, S. M. Cornes, H. R. Holmes, W. J. O'Donnovan, B. C. Tate, J. W. Wigg, A. R. P. Ellis, S. A. Greenwood-Penny, T. A. B. Harris, J. C. Liston, J. Mason, J. G. Stewart, H. J. Hoyte, E. J. Selby, J. Bullock, M. J. Harker.

EMERGENCY COMMISSIONS

To be Lieutenants: L. Fletcher, H. M. Wright, R. B. C. Welsh, J. J. Murphy, J. Finnegan, G. M. B. Wadsworth, J. M P. Clark, R Kenefick, H. J. M. Robinson, J. G. Campbell, L. B. Blomfield, I. A. P. Smythe-Wood, E. R. Greathead, J. B. Stauffer, G. H. A. Simmons, R. N. C Smith, T. V. Somerville, H. C. Bamford, J J. Connolly, G. J. O'Connor, P. Unwin, R. P. Baird, A. D. Cuthbert, C. C Holm, J. P. O'Keefe, W. G. Pollard, D. J. Herrick, E. G. Fleming, and A. W. G. Sutherland.

ROYAL AIR FORCE MEDICAL SERVICE

The following Flight Lieutenants have been granted permanent commissions in that rank: C. C. Barker, J. R. Cellars, D. J. Dawson, G. B. MacGibbon, D. F. S. Shaw

AUXILIARY AIR FORCE: MEDICAL BRANCH

G. B. Hardman has been granted a commission as Flying Officer.

ROYAL AIR FORCE VOLUNTEER RESERVE: MEDICAL BRANCH

Squadron Leader J. G. Skeet, late R.A.F M.S., has been granted a commission for the duration of hostilities in that rank.

G. L. Keynes has been granted a commission as Group Captain for the duration of hostilities.

N. P. Henderson and T. K. Lyle have been granted commissions as Squadron Leaders for the duration of hostilities.

R. B. Bell, N. A. A. Cust, S. Rogers, P. Griffiths, D. M. Anderson, R. R. Foote, A. S. Lee, A. N. H. Peach, B. M. Phillips, J. G. Bate, J. R. Caldwell, K. V. Jackson, G J. Marks, and J. H. McElney have been granted commissions as Flying Officers for the duration of hostilities.

To be Flying Officer: R. J. Healey (name misspelt in the *Supplement* of October 21 (p. 209)).

E. G. Dermer has been granted a commission as Flight Lieutenant for the duration of hostilities.

REGULAR ARMY RESERVE OF OFFICERS

Colonel W. Mitchell, O.B.E., late R.A.M.C., has ceased to belong to the Reserve of Officers on account of ill-health

ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel S. S. Dykes having attained the age limit of liability to recall has ceased to belong to the Reserve of Officers.

Major E. L. Reid, M.C., Union Reserve of Officers, South African Medical Corps, to be Major.

Major P. M. J. Brett has ceased to belong to the Reserve of Officers on account of ill-health

Captains H. Webb, J. H. Barry, and S. R. M Mackay have ceased to belong to the Reserve of Officers on account of ill-health.

Lieutenant J. C. Paterson has resigned his commission.

SUPPLEMENTARY RESERVE OF OFFICERS: ROYAL ARMY MEDICAL CORPS

Captain N. T. Nicholson has resigned his commission.

MILITIA

ROYAL ARMY MEDICAL CORPS

Major C. Atkinson has ceased to belong to the Militia on account of ill-health and has retained the rank of Major.

TERRITORIAL ARMY

Colonel J. P. Clarke, T.D., A.D.M.S., has relinquished his commission on account of ill-health and retained his rank with permission to wear the prescribed uniform.

ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonels A. A. Eagger, J. A. Stenhouse, T D., H. V. Walsh, T.D., and W. Bowater, M C., from Territorial Army Reserve of Officers, R A.M.C., to be Lieutenant-Colonels.

Majors C J. Fox, H. Foxton, M.C., and G. M. Heiron from Territorial Army Reserve of Officers, R.A M.C , to be Majors.

Major J. Rowland, M.C., T.D. has relinquished his commission on account of ill-health.

Captain J. A. S. Brown, from Royal Artillery, T.A., to be Captain, with seniority March 18, 1932.

To be Captains: Captains J. H. Hovell, J. W. M. Sutherland, and B. D. Houston from Supernumerary for service with O.T.C. ; Captains S. G. Reed, S. C. Swinburne, H. B. Dodwell, R. E. Davie, M.C., and D. E. Denny-Brown from Territorial Army Reserve of Officers, R.A.M.C.

J. McG. Rogan to be Captain with seniority March 2, 1938.

Lieutenant P. Kennedy has ceased to hold a commission. (This announcement was wrongly recorded under Royal Army Medical Corps, Regular Army, in last week's *Supplement*.)

Lieutenant W. Gilmour has resigned his commission.

To be Lieutenants: Lieutenant E. A. Sparks, from Territorial Army Reserve of Officers, General List, R.A.M.C. ; Lieutenants A. C. S. Whiteway Wilkinson and C. A. Cromar from Territorial Army Reserve of Officers, R.A.M.C. ; Lieutenant I. Aird from Supernumerary for service with O.T.C.

To be Lieutenants: B. Holden, F. R. O. Hayward, J. E. Talbot, G. E. David, A. Somerville, A. V. Russell, J. H. Gilchrist, W. E. Reynolds, L. V. Arundel, and J. A. Wethered.

TERRITORIAL ARMY RESERVE OF OFFICERS: ROYAL ARMY MEDICAL CORPS

Major R. Kennon, M.C., has relinquished his commission on ceasing to be employed.

Major W. Baxter has relinquished his commission on account of ill-health and has retained his rank with permission to wear the prescribed uniform.

Captain G. F. Shepherd has relinquished his commission on account of ill-health and has retained his rank with permission to wear the prescribed uniform.

Captain D. C. Graham has relinquished his commission and has retained his rank.

Captains D. Cameron and J. K. Davies have relinquished their commissions on account of ill-health.

Lieutenant G. C. Kelly has relinquished his commission on ceasing to be employed.

B.M.A. Branch and Division Meetings to be Held

EDINBURGH AND SOUTH-EAST OF SCOTLAND BRANCH: CITY OF EDINBURGH DIVISION.—The Scottish Eastern Association of the Medical Women's Federation is holding a meeting on Wednesday, November 22, at 3.30 p.m., at the Institute of Animal Genetics, Edinburgh, when a lecture-demonstration on "Modern Methods of Pregnancy Diagnosis" will be given by Professor F. A. E. Crew, F.R.S. The members of the association extend a cordial invitation to attend to members of the City of Edinburgh Division of the British Medical Association.

SUSSEX BRANCH: BRIGHTON DIVISION.—At Brighton Municipal Hospital, Elm Grove, Thursday, November 23, 3 p.m. Clinical meeting; 4.30 p.m., Annual General Meeting, election of officers, etc.

WEEKLY POSTGRADUATE DIARY

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane Road, W.—*Daily*, 10 a.m. to 4 p.m., Medical Clinics, Surgical Clinics and Operations, Obstetrical and Gynaecological Clinics and Operations. *Daily*, 1.30 to 2 p.m., Post-mortem Demonstration. *Tues.*, 2.30 p.m., Lord Horder, Theatre Clinic. *Wed.*, 11.30 a.m., Clinico-pathological Conference (Medical); 2.30 p.m., Clinico-pathological Conference (Surgical). *Thurs.*, 2 to 4 p.m., Dr. Duncan White, Radiological Conference. *Fri.*, 2 p.m., Clinico-pathological Conference (Gynaecological).

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

Section of Surgery.—Wed., 2.30 p.m. Dr. J. Trueta: The Treatment of War Fractures by the Closed Method.

WAR NOTICES

1. THE EMERGENCY HOSPITAL MEDICAL SERVICE

The recommendations for the reorganization of the Emergency Medical Service, which were made to the Minister of Health by the Advisory Emergency Hospital Medical Service Committee established by the Central Emergency Committee, are as follows.

It is urged that, in the light of the experience gained and bearing in mind that the original assumptions upon which the service was founded may at any time come true, the Emergency Medical Service should be reorganized. It is recognized that the Ministry has already entered into a number of contracts for the period of a year and that it may not be desirable or practicable for the Ministry to modify these contracts. This consideration may necessitate postponement of the reorganization in some directions.

The following recommendations are put forward.

(1) The Ministry of Health should now, in consultation with hospital authorities and the Central Emergency Committee, (*a*) reconsider the number and distribution of beds authorized for the purposes of the Emergency Medical Service, and (*b*) determine a policy of staffing in relation to authorized beds.

(2) By application of this policy definite establishments for the different classes of officer in each grade should now be laid down.

(3) There should be three classes of officer in the reorganized Emergency Medical Service:

Class I.—Whole-time officers, resident or non-resident, who will not be permitted to engage in private practice. Officers in this class should be permitted, subject to the consent of the Ministry, to hold teaching, examining, and other academic appointments and receive fees therefrom.

Class II.—Part-time officers, resident or non-resident, who will be free to engage in private practice. Such officers will be liable for duty as and when required, the salary or retaining fee to cover all such duties.

Class III.—Part-time officers remunerated on a sessional basis.

Class I

(4) The authorized Class I establishments should be the minimum consistent with efficiency and comprise administrative officers, house officers, officers of the standing of registrars, resident surgical and medical officers, and other key officers.

(5) Class I officers within the authorized establishments should be called up on enrolment and employed and paid at the appropriate rates.

Class II

(6) (*a*) Under the new arrangement there would be eligible for appointment within the authorized establishment doctors of recognized consultant status—for example, those who are now enrolled or employed in Classes A (*d*) and (*e*) of the existing service.

(*b*) Those engaged under the new plan would receive a fee at the rate of £500 per annum from the Ministry for the balance of the period for which employment is contracted for under their present agreement. They would be expected in return for this fee to render all such services appropriate to their grade in the Emergency Medical Service as are required in connexion with the emergency hospital organization. No number of sessions per week or other limit would be laid down. They would be expected at all times to render as much service as might be necessary without any increase in remuneration.

(*c*) They would not be expected, as in the case of whole-time officers of the Emergency Medical Service, to accept a liability under the Emergency Medical Service to serve anywhere in the country. They would normally be attached either to a single hospital or to a group of hospitals, on the understanding that their services might be required in special circumstances at other hospitals within a reasonable distance.

(*d*) Officers not required to live away from home, and stationed at hospitals more than two miles from their homes, would be paid a travelling allowance related to both mileage and timage. Officers required to live away from home would receive free board and lodging, or £100 in lieu thereof. In order to avoid correspondence, etc., an attempt would be made to fix definite sums for travelling appropriate to radial distances from home, subject to review at reasonable intervals.

(*e*) A limited number of specialists would be expected to travel anywhere within the sector and possibly indeed outside it. Their travelling allowances would have to be adjusted accordingly.

(*f*) The Advisory Emergency Medical Service Committee would use its best endeavours to induce those at present enrolled on a whole-time basis at £800 and over to accept the new proposal. If individuals prefer to insist on the terms of their present contract the Ministry would be bound by it, in just the same way as those now serving whole-time are bound by the conditions of the contract, including the obligation to refrain from private practice.

(*g*) Class II officers, as they are liable for whole-time duty as and when required, should be entitled to official leave with pay, and to sick pay during temporary absence.

Class III

(7) Appointments should be made to Class III only where one or more of the following conditions obtain:

(*a*) Where a practitioner, not receiving a part-time salary or retaining fee, is called to attend to treat patients within the scope of the Emergency Medical Service at a local authority hospital with a resident medical staff.

(*b*) Where a practitioner, not receiving a part-time salary or retaining fee, is called to attend to treat patients within the scope of the Emergency Medical Service at a hospital in buildings specially adapted for the purpose, this hospital having a resident medical staff.

(*c*) Where a practitioner, not receiving a part-time salary or retaining fee, is called to attend to treat patients within the scope of the Emergency Medical Service at a hospital to which are attached Class I officers, other than house officers, undertaking clinical work.

(8) All practitioners not enrolled in Class I, II, or III treating at voluntary hospitals patients coming within the scope of the Emergency Medical Service should be remunerated in the following way:

The Government should add to the maintenance cost payable to the hospital under the existing arrangement an agreed amount in respect of medical services, other than those given by the resident medical staff, the hospital to pass such payments directly to the practitioner or practitioners undertaking the work, or to the hospital staff fund, or to a group staff fund, as the staff may desire.

(9) There should be special provision for payment in respect of mileage for Class III officers.

(10) (*a*) The Ministry should now decide, after consultation with the Central Emergency Committee and the Group Officer concerned, the establishment of house officers necessary to staff the beds officially authorized to be set aside for the purposes of the service in the grouped hospitals.

(*b*) The hospital authorities to which emergency house officers within the establishment are allocated should, in consultation with the Group Officer, make the necessary appointments, the Ministry paying such hospital authorities at the rate of £200 per annum per authorized house officer plus board and lodging.

(*c*) Hospital authorities would be free to pool the salaries of the house staff, including the amounts received from the Ministry in respect of emergency house staff, and apportion it between the house officers generally.

(*d*) The permissive arrangement set out in paragraphs (*b*) and (*c*) should be available to both voluntary and municipal hospitals. It may be necessary to make special arrangements in regard to the method of appointing house officers at a hospital established in a building not formerly used for general hospital purposes, but it is suggested that such officers might be "carried" on the staff of one of the main hospitals of the Group.

(*e*) The Central Emergency Committee would not recommend for appointment to the Services any practitioner within six months of registration. Hospital authorities would be asked to make their junior house appointments from practitioners within six months of registration and to limit those appointments in all cases to six months.

(*f*) There should be established a new category of practitioners in the Emergency Medical Service consisting of practitioners who have served for at least six months as house officers who have not been qualified for more than three years. Such senior house officers would be enrolled individually by the Ministry as members of the service and paid at the rate of £350 a year, plus board and lodging.

Minister's Reply

The Minister has indicated his general agreement with the recommendations, subject to the following observations.

1. The establishment of Class I officers will consist of a nucleus staff, the size of which will be determined by the minimum requirements of each hospital, having regard to its character and the part which it is intended to play in the emergency scheme. It will be clearly understood that in the case of these officers the requirement not to engage in private practice must be strictly observed.

2. In the case of Class II officers, to whom a part-time salary of £500 a year is to be paid, the establishment will be determined on the basis that only part-time work will be required at present, but it is understood that if hostilities should become so intensified as to require prolonged additional work, no claim for additional remuneration will be made. In so far as there are vacancies in the Class II establishment for officers who have been or may hereafter be enrolled for whole-time service but not called up, they will be eligible for employment on the same terms as those already serving. In the event of whole-time officers being transferred to Class II the above arrangements will continue in operation for the remainder of the period for which employment was guaranteed under the terms of their original contracts.

3. Where Class II officers who have served for three months are absent on leave or through sickness no deductions will be made from their salary on that account, but it is understood that other officers serving in the Emergency Medical Service will act as their substitutes and perform duty without claim for extra remuneration.

4. The travelling allowances for Class II officers will be fixed, in consultation with the Advisory Committee, having regard to radial distances in excess of two miles from their homes and to other relevant circumstances.

5. The arrangement proposed in recommendation 8 (that is, remuneration of medical staff by an addition to the payments now being made to hospitals) would not operate in hospitals where Class I officers (other than administrative or house officers) or Class II or III officers were employed. In fixing the rate of payment to the hospital it is necessary to take account of the types of cases for which the Emergency Medical Service is employed, the number of such cases likely to be found in any one hospital, the equivalent salaries of whole-time officers, and a number of other factors. The Minister is prepared to fix a flat rate in payment for medical services of 1s. 6d. per day (that is, 10s. 6d. per week) per bed occupied by a case within the scope of the Emergency Medical Service. Provision will be made for payment for medical services rendered at out-patient departments in the same class of hospital by adding 6d. to the sum payable for each out-patient attendance. It will be appreciated that in addition the cost of the services of any house officers employed on a salaried basis would fall upon the Department either by direct payment or by inclusion in the hospital's emergency costs.

6. In applying the pooling arrangements proposed for house officers, officers seconded to hospitals (including municipal institutions) other than those by which they were appointed may be regarded as belonging to the latter hospitals.

7. The appointments at £350 a year referred to in recommendation 10 (*f*) would be strictly limited in number, and house officers would have no right to succeed automatically to them on the termination of their house appointments.

8. The classes of case for which the Emergency Medical Service are employed are as follows:

(1) Civilian casualties arising in Great Britain from hostile attack. (Injured persons taken from ships damaged by enemy action will be included.)

(2) Casualties from H.M. Forces and Women's Organizations attached thereto. (These include all cases of injury whether or not caused directly by enemy action or whether arising in this country or outside.)

(3) Sick from H.M. Forces, etc., as above, whether arising in this country or not.

(4) Prisoners of war (and interned persons), whether sick or injured.

(5) Police casualties and sick.

(6) Unaccompanied children evacuated under the Government evacuation scheme. (This does not cover other evacuated classes who are the responsibility of the local authority in so far as they do not make their own arrangements for treatment.)

(7) " War Service " injuries. (These are accidents incurred by civil defence volunteers as defined in the Ministry of Pensions scheme, if the accident occurs in the performance of their duty.)

(8) Patients, not in any of the above categories, transferred from one hospital to another under the Emergency Hospital Scheme by arrangement with the Hospital Officer (the " transferred sick ").

9. Consideration has also been given to the position of officers who are now serving full-time with the Emergency Medical Service but who, although called up by the Group Officers, had not entered into written contracts. The Minister will regard these officers as employed on the same terms as those who have entered into written agreements, provided that they are now prepared to enter into such an agreement. The same options will then be open to them as if they had been serving under such an agreement from the beginning.

The Advisory Emergency Medical Service Committee has accepted the position as set out in the Minister's reply, on the understanding that the rate of 1s. 6d. a day in paragraph 5 of the Minister's observations is without prejudice to what should be a proper figure in peace time, and that the position will be reviewed in the light of experience for the period ended June 30, 1940. It urges practitioners concerned to accept the terms and conditions of the reorganized Service.

2. MEDICAL STAFFING OF FIRST-AID POSTS

In response to the representations made by the British Medical Association to the Minister of Health and described in earlier issues of the *Supplement* on the subject of the medical staffing of first-aid posts, the Minister has replied in the following terms.

1. A medical officer should be in complete charge of each first-aid post instead of being only responsible for the training of the personnel as he is under present arrangements. At present the medical officer of health is directly responsible for all the posts in his area, but it is desirable that there should be a definite link in the chain of command between him and the first-aid posts as they are now functioning.

2. The staffing arrangements are, in the first instance, a matter for the local authority to propose as part of their first-aid post scheme, but the Minister will ask them to arrange for the medical officers at present assigned to the posts or, if they are unwilling, other practitioners selected for the purpose, to undertake complete charge of the post, supervising not only the volunteer personnel but also the trained nurse, even if she is an officer of the local authority. They would continue to conduct the collective training of the personnel on the lines indicated in Circular 1831 dated June 22, 1939; they would also undertake the responsibility for stores and the general maintenance of the post and any correspondence on administrative matters relating to the post, so that they would, in effect, be acting as temporary officers of the local authority. In order to keep the post and the personnel properly under supervision they would be expected to visit the post at least three times a week and to be prepared to attend during an actual air raid if required. One or more other doctors might also be retained to attend during a raid, but they would have no responsibility for the general supervision of the post.

3. The above arrangements would apply only to the more vulnerable areas—that is, those specified by the Minister of Home Security under Part III of the Civil Defence Act, 1939. Mobile first-aid posts in these areas would be included in the arrangements.

4. Local authorities will be authorized to pay a salary at the rate of £75 a year for each aid post in consideration of the performance of duties as set out above, the employment being for six months in the first instance, subject to a month's notice on either side. In addition, in the event of the doctor being required to attend the post owing to an actual air raid upon the locality, sessional fees would be payable at the rates already agreed upon—namely, one and a half guineas for a session of not more than two hours and three guineas for a session of longer duration.

5. Further, as it is understood that on the outbreak of war medical officers were in some instances required by the medical officers of health to attend their posts on a sessional basis notwithstanding the non-occurrence of raids, the payment of sessional fees will be authorized in cases where sessional attendances were required and given before the receipt of Circular 1869 issued on September 9, 1939.

6. The financial arrangements which are described would be in substitution for the payment of twenty guineas already in operation, the necessary adjustment being made as at the date from which the change of duties comes into operation.

7. In case of first-aid posts situated at hospitals these arrangements would be modified to suit the circumstances.

In areas not covered by this scheme it is understood that the existing authority to employ medical officers to supervise collective training at 20 guineas a year will continue in force.

The Central Emergency Committee has approved the proposed new arrangements.

3. SPECIALISTS AND THE SERVICES

In the War Notices in the *Supplement* of September 16 (p. 181) it was stated that medical practitioners appointed as specialists to the R.A.M.C. would, on appointment to a hospital post, be granted the rank of major. This has given rise to some misunderstanding, and it is desirable to point out that the rank of acting major is granted only to those practitioners *appointed as specialists* to posts within the authorized establishment.

CENTRAL EMERGENCY COMMITTEE
(Central Medical War Committee),
British Medical Association House,
Tavistock Square, W.C.1.

Suggestions for improving the working of the evacuation scheme and for lightening the burden of hosts in the reception areas are made by the Minister of Health, Dr. Elliot, in a communication to local authorities. Three ways of helping the householder are suggested: (1) By communal meals and out-of-school activities for the children; (2) where possible, by a redistribution of billeting; (3) by greater consideration on the part of parents, particularly those who expect free hospitality from the householder when they visit their children. Applications from some householders to be relieved of their burden, at least temporarily, should be sympathetically considered and, so far as possible, met.

TWO NEWSPAPERS APOLOGIZE

Under the heading "The Banned Doctor" the following "news story" appeared in the *Sunday Pictorial* of November 5, 1939:

> "Because they do not belong to the British Medical Association, or have not rendered 'past services' to the Association, 23,000 doctors, it is declared, may never get a chance of serving with the Forces.
>
> These doctors, according to men prominent in the medical profession, are victims of one of the greatest ramps and profiteering scandals of the war.
>
> Doctors are recruited for the three Forces—Army, Navy, and Air—through the B.M.A. Applications for commissions are first made to local committees of the Association.
>
> 'Unless a doctor belongs to the B.M.A.,' a well-known West End doctor told the *Sunday Pictorial*, 'his application to serve is most likely just filed and conveniently forgotten.'
>
> The West End doctor cited two instances of how 'favouritism' operates in certain cases.
>
> Two doctors have a good practice. They have each been awarded five 'Boards' a week for examining recruits.
>
> 'For each Board they receive £2 2s. Thus their practice is richer by £21 a week.'
>
> 'JOBS KEPT OPEN.'
>
> Another man who practised dentistry, but never touched medicine, has been appointed as a qualified examiner.
>
> Meanwhile, other doctors see their incomes rapidly depleted as the result of evacuation and the calling up of men.
>
> 'It is a scandal that Government money should be used by an association for the payment of past services,' said the West End doctor. 'But that is happening.
>
> 'Certain local branches of the B.M.A. are keeping jobs open nicely for their members.'
>
> Of 60,000 doctors in this country, the B.M.A. claim 37,000 as members."

On November 19 the *Sunday Pictorial* published the following statement:

British Medical Association

An Apology

> "The news story entitled 'The Banned Doctor,' published in our issue of November 5, reflected on the British Medical Association by alleging that the Association in selecting doctors for the various forms of National Service was discriminating unfairly against doctors who were non-members or who had not rendered 'past services' to the Association.
>
> There is no justification for these allegations.
>
> We find on investigation that the Association is completely impartial, offering to non-members and members alike the same opportunities for service. We desire to express to the Association and to those responsible for the administration of the Central Medical War Committee our apologies and sincere regret for having published such statements."

A shorter form of the offending news story appeared in the *News Review*, which has since published an apology on lines similar to that in the *Sunday Pictorial*. These two newspapers have agreed to pay the Association's legal costs and, in addition, a sum of 100 guineas in the case of the *Sunday Pictorial*, and a sum of 50 guineas in the case of the *News Review*. The 150 guineas thus paid to the Association is being forwarded as a contribution to the Lord Mayor's Fund for the British Red Cross.

Assurance for Doctors

Cars used for Civil Defence

An announcement indicating a radical rearrangement of the position with regard to motor cars used for civil defence has now been made by insurance companies and underwriters in collaboration with the Home Office. The material points are as follows: The individual policy no longer covers the use of cars for civil defence, and persons using their cars for this purpose should acquaint themselves with the position.

Full-time Usage.—Owners should immediately get in touch with the local authority concerned, who will be aware of the details of the special policy to be issued, and should arrange with the authority whether the existing policy is to be converted or a new policy, usually at a flat rate of premium, is to be taken out. If a new policy is taken out by the authority the companies have agreed to a *pro rata* return of premium under the original policy.

Part-time Usage.—Instructions have been given to local authorities to take out "block" policies covering the cars of all their part-time workers, the premium not to exceed £2 per vehicle. Here again the policy-holder should get in touch with the local authority to make sure that the necessary arrangements are made for his car to be included under the general scheme. The insured will, of course, be protected under the "block" policy while engaged on civil defence work and under his own normal policy at other times. The owner will have this advantage, that should he meet with an accident while on civil defence work the no-claim bonus under his own private policy will not be invalidated. The premium on the "block" policy is payable by the local authority.

This scheme has already come into operation, but it is doubtful whether all the members affected under the Civil Defence Services are familiar with it. Any person who is uncertain of his position is recommended to take up the matter with the local authority employing him, and any other information can be obtained from the Medical Insurance Agency, B.M.A. House, Tavistock Square, W.C.1.

Correspondence

Notification of Measles and Whooping-cough

SIR,—As the Ministry of Health has not seen its way to agree to the fee of 2s. 6d. for the notification of measles and whooping-cough, I suggest that they be informed that unless that fee is agreed to the B.M.A. will instruct all members to refuse to notify these diseases until such time as the fee is accepted by the Ministry. If we allow this to pass and accept a fee of 1s. there is not the slightest doubt that in a very short time the fees for other notifications will be reduced to the same figure.

Considering the increased cost of living and increased taxation it would be more to the point if all notification fees were increased by 1s. each.—I am, etc.,

Wetherby, Nov. 11. S. T. PYBUS, M.D.

SIR,—Is it not possible for the profession for once to make a firm stand against this imposition by the Minister of Health? I refer to the fee of 1s. for notification of cases of measles and whooping-cough throughout the country. Upon what grounds is the Minister making this reduction in fee? With living expenses rising upon every hand and no corresponding increase in the capitation fee for panel patients, what right, I ask, has the Minister to do this?

Now surely there are no men in the profession so without that sense of loyalty to each other that they would refuse to join in an active and practical protest against this unjust imposition? Surely it is possible just for once for us all to stand together and as a body refuse to sign one single notification until the full normal fee of 2s. 6d. is restored. The Council of the Association has stated its disagreement with the fee and will surely back us up. Therefore if only we are sufficiently determined to resist what is only too likely to be the thin end of the wedge we can prevent this type of exploitation.—I am, etc.,

Ludlow, Nov. 15. VICTOR N. FENTON.

⁂ The Secretary of the British Medical Association states that the Association has been assured that this fee of 1s. will not apply to other diseases which are at present notifiable.

AIR RAID CASUALTIES

Dr. J. Trueta, late Director of the Department of Surgery, General Hospital of Satalunya, Barcelona, will give an address on "The Medical and Surgical Assistance of Minor Injuries in Bombarded Towns" in the Great Hall, B.M.A. House, Tavistock Square, W.C.1, on December 5, 1939, at 2.45 p.m. The address has been arranged by the City Division of the Metropolitan Counties Branch of the B.M.A., and all members of the Branch are invited to attend.

British Medical Association

OFFICES, BRITISH MEDICAL ASSOCIATION HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1.

Addresses, etc.

SECRETARY (Telegrams: Medisecra Westcent, London).

EDITOR, BRITISH MEDICAL JOURNAL (Telegrams: Aitiology Westcent, London).

Areas of Stockport and Macclesfield and East Cheshire Divisions

With reference to the preliminary notice which appeared in the *Supplement* of October 21 (p. 210), notice is hereby given by the Council of the British Medical Association to all concerned that as from the date of this notice the urban district of Cheadle and Gatley is transferred from the area of the Stockport Division to that of the Macclesfield and East Cheshire Division.

G. C. ANDERSON,
Secretary.

Branch and Division Meetings to be Held

GLOUCESTERSHIRE BRANCH.—Clinical meetings of the Branch have been suspended until further notice.

METROPOLITAN COUNTIES BRANCH: CITY DIVISION.—At B.M.A. House, Tavistock Square, W.C., Tuesday, December 5, 2.45 p.m. Dr. J. Trueta: "The Medical and Surgical Assistance of Minor Injuries in Bombarded Towns."

SOUTHERN BRANCH: ISLE OF WIGHT DIVISION.—At Isle of Wight County Mental Hospital, Whitecroft, Newport, Tuesday, November 28, 3.15 p.m. Lecture by Dr. Stanley White: "Recent Advances in the Clinical Applications of the Sex Hormones."

Meetings of Branches and Divisions

DORSET AND WEST HANTS BRANCH: BOURNEMOUTH DIVISION

At a meeting of the Bournemouth Division, held at Boscombe Hospital on November 8, with Mr. S. GORDON LUKER in the chair, Sir KAYE LE FLEMING and Dr. WALTER ASTEN reported on the Annual Representative Meeting at Aberdeen in July. Dr. O. C. CARTER then gave an address on "The Local Emergency Committee and its Work," and Sir KAYE LE FLEMING referred to the work of the Central Emergency Committee. It was agreed to hold the next meeting of the Division on January 24.

SUSSEX BRANCH: WEST SUSSEX DIVISION

At a meeting of the West Sussex Division held on October 25, with Dr. C. GIBSON in the chair, Dr. DONALD HALL (Brighton) read a paper on "Functional Derangements of the Heart" and showed radiographs of various heart conditions. After supper a discussion on the paper was opened by Dr. MORLEY FLETCHER and was continued by several other members.

LIBRARY OF THE B.M.A.

It is requested that members of the B.M.A. proceeding on service will return all library books and journals.

The Library service is one of the privileges available to members of the British Medical Association resident in Great Britain and Ireland. Full particulars will be forwarded on application to the Librarian, B.M.A. House, Tavistock Square, London, W.C.1.

The following volumes were added to the Library during September.

Postgraduate News

The Fellowship of Medicine announces the following postgraduate courses to be held in preparation for the F.R.C.S. (Final) Examination in February, 1940: comprehensive course, including clinical instruction, in the wards and out-patient department, lectures, *x*-ray and museum demonstrations, and tutorial classes (including answering set questions). The course will be given from December 11, 1939, to January 27, 1940 (excluding Christmas holidays), from 9.30 a.m. to 1 p.m. Mondays to Fridays, and 11 a.m. to 1 p.m. Saturdays. Short courses in pathology will also be given, each consisting of two demonstrations (in the same week) from 2 p.m. to 3.30 p.m., and limited to six postgraduates. The course will be repeated every week until the examination (for fresh classes of six postgraduates) if there is sufficient demand. No postgraduate may attend more than one course.

A short course in tropical medicine and hygiene, lasting six weeks, will begin at the London School of Hygiene and Tropical Medicine on Monday, January 8, 1940, at 10 a.m. The fee will be ten guineas. Although certificates of attendance will be given, the course will not in any way qualify for admission to the examination for the Diploma in Tropical Medicine and Hygiene. It is intended that the classes will be held in the school premises in Keppel Street, W.C., but in the event of war conditions making this impossible arrangements have been made to transfer teaching to the school's branch institute at St. Albans. Similar courses will be held from time to time during the year should sufficient applications for admission be received. Inquiries should be addressed to the secretary, London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C.1.

WEEKLY POSTGRADUATE DIARY

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane Road, W.—*Daily,* 10 a.m. to 4 p.m., Medical Clinics, Surgical Clinics and Operations, Obstetrical and Gynaecological Clinics and Operations. *Daily,* 1.30 to 2 p.m., Post-mortem Demonstration. *Mon.,* Beginning of course for Final F.R.C.S. *Tues.,* Lord Horder, Ward Clinic. *Wed.,* 11.30 a.m., Clinico-pathological Conference (Medical); 2.30 p.m., Clinico-pathological Conference (Surgical). *Thurs.,* 2 to 4 p.m., Dr. Duncan White, Radiological Conference. *Fri.,* 2 p.m., Clinico-pathological Conference (Gynaecological).

FELLOWSHIP OF MEDICINE AND POSTGRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.—*Brompton Hospital,* S.W.: Mon. and Wed., 4.30 p.m., M.R.C.P. Course in Chest Diseases.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

Section of Odontology.—Mon., 2.30 p.m. Paper by Professor A. Fleming: Antiseptics and Chemotherapy. Short communication by Dr. A. J. Cokkinis: Sulphonamide Chemotherapy and its Effects on Gingivitis and Pyorrhoea.

Section of Otology.—Fri., 10.30 a.m. Discussion: The Transmeatal Approach to the Mastoid. Openers: Dr. G. B. Brand, Mr. Walter Howarth, Mr. G. Bateman. Cinematograph film. Mr. John Gerrie: The Transmeatal Approach to the Mastoid.

Section of Laryngology.—Fri. 2.15 p.m. (Cases at 1.30). Clinical meeting: Cases will be shown illustrating the various forms of orbital complications of sinus disease, with a view to discussing whether the advent of sulphanilamide should modify the approach to the case.

Section of Anaesthetics.—Fri., 2.30 p.m. Paper by Dr J F. Taylor: Status Lymphaticus

ROYAL INSTITUTION, 21, Albemarle Street, W.—*Tues.*, 2.30 p.m., Sir Frederick Keeble, F.R.S.: Food Production in War Time.

Naval, Military, and Air Force Appointments

ROYAL NAVAL VOLUNTEER RESERVE

To be Temporary Surgeon Lieutenants: W. A. Hutton, N. W. Pryde, A C. K. Yates, P. W Houghton, E Elmes, N. J Haggar, J. W. Shield, M G. Low, R. Jackson, J. D. Sidey, H. A. R. Hamilton, J. W. Ashley, W H A. Picton, E R. L. Davies, J. G. Bryson, D F. Heath, and D. Bennett.

Probationary Surgeon Lieutenant R. J. C. Sutton to be Surgeon Lieutenant, with seniority October 19, 1938.

ROYAL ARMY MEDICAL CORPS

Emergency Commissions

To be Lieutenants: J. C. Bell, D Dean, F. Porter-Smith, J. L. Gilloran, A H Imrie, R. McCombe, J. M. Ritchie, P C. Robertson, G. K. Wood, W Giles, J. B Harrower, B. A. Moss, R. C L'E Burges, J. Baird, G S. Broadbent, R. L. Boutne, D M Carding, G Christie, E. B. Davies, P. J. Honan, W. Wilson, D. G. Robinson, A. T. Hastie, W. G. T. McFie, T. B. Bailey, M R. Joseph, A. McDonald, J W. Dowzer, C. S. Hemming, J. A Chamberlin, H. C Calvey, J W P Collier, W. Finlay, J. Hodge, J P Kilty, E J. O'Loughlim, M C. Dickson, T G. Anderson, J D Durance, C V. Spark, J. Sinclair, D E. Bedford, H. R. Miller, K. C Burrow, C E. Burley, W. H. D Davies, A D. Aveling, A. T Rogers, G Forrest-Hay, S Boan, J. Lavery, G Williams, W. F. Green, P. T. Harper, S Dobbin, E. E. Prebble, W. L Ackerman, A. G. Aitkin, H. A. Mullen, R. W. M. Strain, G W. Reid, G D Park, B. J. Harries, I. F Rose, C. L. Carter, H S. Hamlin, J. R Dickinson, J. D. Horsburgh, T S Severs, T. M. Doran, A. N. Mathias, G. K. Kirwan-Taylor, J. H. Neill, W R. Topping, S. C. Truelove, R. H Baird, S. Grodd, R. J. Milbank, L. J. Blay, J F H. Bulman, J. M. Duff, E C. Fernandes, E L. Fawssett, W. N. McArthur, D. Strong, C. Taylor, J. P. B. Ball, R. S. Dale G. W. Newton-Dunn, M. A. Imray, C. D. Macrae, G. A. Owen, D. C. Porter, J E. Symondson, S. C. Wake, N. P. Woodgate-Jones, P. Baker, H. G. Burford, J. L. Hart, J. M Holmes, F. G. Leslie, H. G. Poles, A. C. Rumsey, N. E. Montewcis, W. G. Brown, R. C. Droop, T C. Gilliland, E. W. Hart, R. S. Lewis, L. A. Willmot, H S. Lanceley, W. G. V. Said, J. A. Edward, A. M. Davidson, F. Austin.

Auxiliary Air Force: Medical Branch

J. Cann has been granted a commission as Flying Officer.

Royal Air Force Volunteer Reserve: Medical Branch

C. P. Symonds to be Group Captain for the duration of hostilities.

R. D. Gillespie to be Wing Commander for the duration of hostilities.

P H Lomax, R G D Forward, D. H. Fowler, B. A. E. Harley, J North, S. F. Robertson, S. Segal, F. N. Shuttleworth, and D. Turner have been granted commissions as Flying Officers for the duration of hostilities.

REGULAR ARMY RESERVE OF OFFICERS

Royal Army Medical Corps

Captain (Brevet Major) J. Gilmour, C.M.G., M.C., having attained the age limit of liability to recall, has ceased to belong to the Reserve of Officers.

TERRITORIAL ARMY

Colonel L. E. H. Whitby, C.V.O., M.C., from Territorial Army Reserve of Officers, R.A.M.C., to be Colonel.

Colonel C H S. Redmond, T.D. having attained the age limit, has retired and retained his rank, with permission to wear the prescribed uniform.

Royal Army Medical Corps

Majors C E. Kindersley, H. J Heathcote, P. W. McKeag, and G W. Wigg, T.D., from Territorial Army Reserve of Officers, R.A.M.C., to be Majors.

Majors J. H. Blackburn, M.C., and L. N. Jackson, M.C., have relinquished their commissions on account of ill-health.

Captain (Brevet Major) J. E McCartney to be Major.

Captains H. A. Eccles, A. McCampbell, E H. Brindle, E. M. R. Frazer, and A V Mackenzie, M.C., to be Majors.

Captains H. G. Neill and E. A Downes from Territorial Army Reserve of Officers, R.A.M.C., to be Captains.

Lieutenant H. R. Shields to be Captain, with seniority April 26, 1938.

Lieutenants R. S. F. Schilling, R. Brown, A. Browning, B. St. J. Steadman, J. Clay, and H R W. Lunt to be Captains.

Lieutenant H. R. Vernon from Territorial Army Reserve of Officers, R.A.M.C., to be Lieutenant.

Lieutenant H W. Whitcher from Infantry Unit, Edinburgh University Contingent, Senior Division, O.T.C., to be Lieutenant.

W. E Johnston and W. E. G Bradford to be Lieutenants

Second Lieutenant A. E Stevenson from Territorial Army Reserve of Officers, General List (Infantry), to be Lieutenant.

Territorial Army Reserve of Officers: Royal Army Medical Corps

Captains G. G. Johnstone, M.C., and G. M. Miller, M.C., have relinquished their commissions on account of ill-health.

INDIAN MEDICAL SERVICE

Colonel D. H. Rai, M.C., has been appointed as officer on special duty in the office of the Director-General, Indian Medical Service, as from October 9 or any subsequent date on which he assumed charge of his duties.

Lieutenant-Colonel T. C. Boyd to be Colonel, with seniority February 1, 1931.

Lieutenant-Colonels K. S. Thakur and M. A. Nicholson have been advanced to the List of Special Selected Lieutenant-Colonels.

The Central Government has nominated Lieutenant-Colonel W. C. Paton, M.C., Inspector-General of Civil Hospitals and Prisons, North-West Frontier Province, to be a member of the Medical Council of India, from the North-West Frontier Province, as from October 3.

Lieutenant-Colonel W. J. Webster, M.C., has been appointed as Assistant Director, Central Research Institute, Kasauli, with effect from October 1.

Lieutenant-Colonel W. P Hogg, M.C., Chief Medical Officer and Inspector-General of Prisons in Baluchistan, has been granted leave on average pay for three months and ten days, under the Fundamental Rules, with effect from August 23

Major E O'Connor, an Agency Surgeon, has been employed to officiate as Chief Medical Officer and Inspector-General of Prisons in Baluchistan with effect from August 23.

Major W. T. Taylor has taken over charge of the Medical Store Depot, Madras, with effect from September 4.

Captain R. L. Haviland-Minchin, Assistant Director, Central Research Institute, Kasauli, has been appointed a leave reserve officer against the Central Indian Medical Service cadre, with effect from October 1.

Captain G W. Millar has been attached to the Port Health Department, Bombay, as a leave reserve officer under the Central Government, from July 21 to July 31, and has been appointed to officiate as Port Health Officer, Bombay, from July 31, 1939, until further orders.

Captain (on probation) G C. A Jackson has relinquished his probationary appointment on account of ill-health.

Lieutenant Thein Maung to be Captain.

COLONIAL MEDICAL SERVICE

The following appointments are announced: R. B T. Baldwin, M.R.C.S., L.R.C.P., Medical Officer, Nigeria; A. L de P Carnegie, M.B., Ch.B., Medical Officer, Jamaica; J. W P. Harkness, O.B.E., M.B., Ch.B., D.P.H., Director of Medical Services, Gold Coast; J O. Poynton, B.Ch., Pathologist, Institute for Medical Research, Federated Malay States; W. L. Webb, M.B., B.S., D.P.H., Senior Medical Officer, St. Vincent.

VACANCIES

Examining Factory Surgeons.—The following vacant appointments are announced: (1) Leeds West and Farsley (Yorkshire, West Riding). (2) Beverley (Yorkshire, East Riding). Applications to the Chief Inspector of Factories, Home Office, Whitehall, S.W.1, by December 4.

Medical Referee under the Workmen's Compensation Act, 1925, for the West Hartlepool County Court District (Circuit No. 2). Applications to the Private Secretary, Home Office, Whitehall, S.W., by December 3.

APPOINTMENTS

Armstrong, C. N., M.D., B.S., B.Hy., D.P.H., M.R.C.P., Honorary Physician, Royal Victoria Infirmary, Newcastle-upon-Tyne.

Illingworth, R. S., M.D., D.P.H., D.C.H., M.R.C.P., Nuffield Research Student in Medicine, Radcliffe Infirmary, Oxford.

Morgan, A W. J., M.R.C.S., L.R.C.P., D.P.H., District Medical Officer, Khargpur, Bengal Nagpur Railway, Bengal.

Nicol, C. Grant B.M., B.S., D.P.H., Assistant County Medical Officer and Medical Officer of Health for Uttoxeter Urban and Rural District Councils.

Examining Factory Surgeons.—F. H. E. Beckett, M.R.C.S., L.R.C.P., for the Manningtree District (Essex); R. G. R. Burrows, M.B., B.Ch., for the Melling District (Lancashire), D Craig, M.D., for the Stanford-le-Hope District (Essex); D. B. Davies, M.B., Ch.B., for the Kidwelly District (Carmarthenshire); A. N. Jackson, M.D., for the Handsworth District (Yorkshire, West Riding).

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this heading is 9s. This amount should be forwarded with the notice, authenticated by the name and address of the sender, and should reach the Advertisement Manager not later than the first post Tuesday morning to ensure insertion in the current issue.

BIRTHS

Monro.—On November 17, in Singapore, to Landon Carter (*née* Reed) and J. K. Monro, M.Ch., a son

Vollam.—On November 14, to Dr. and Mrs. F. Harman Vollam (*née* Eleaner Davis), at Cornhill, Rubery, a daughter.

DEATHS

Cunningham.—On November 10, 1939, very suddenly, at 29, Wilbury Road, Hove, Francis William Murray Cunningham, D.S.O., F.R.C.P.Ed., M.R.C.P.Lond., Senior Honorary Physician, Royal Sussex County Hospital Aged 55. Beloved husband of May Cunningham, son of the late William Murray Cunningham, W.S., of Glasgow, and of Mrs Cunningham, now of Hove.

McDonald.—At Belford Villa, Belford, Northumberland, on November 19, 1939 Mima Raugh, wife of James McDonald, M.D.

Prout.—On November 18, 1939, at Manor House, Lingfield, Surrey, Lieut.-Colonel Sir William Prout, K.C.M.G., O.B.E., M.B., C.M.

The chairman, Dr. J. Gordon Hume, and members of the medical board entertained to dinner at the Trocadero Restaurant on November 9 the officers and staff of the Artists Rifles, at whose depot the applicants for commissions were examined. The local medical board was instituted by the Emergency Committee of the St. Pancras Division of the British Medical Association.

WAR NOTICES

The Emergency Medical Service

To the Editor of the "British Medical Journal"

SIR,—We should like strongly to commend to the favourable consideration of all officers working in it the changes in organization in the Emergency Medical Service as explained by the Minister of Health last week. The new conditions are the result of prolonged negotiations with the Ministry, and although inevitably they are in some points a compromise we believe them to be a substantial improvement upon the old. In particular it is to be hoped that the more favourable terms for part-time service will induce many whole-time officers to transfer to part-time and so make their skill and experience available to the general public instead of being to a large extent wasted as they are at present. Individual cases of hardship and inconvenience there are bound to be, but we are confident that these will be borne with the public spirit which has always characterized our profession.

May we take this opportunity of referring to another matter? There is a suspicion amongst some doctors that the Ministry of Health may be proposing to use the E.M.S. as the thin end of the wedge for a post-war State Medical Service. We can assure such, on the highest authority, that nothing is further from the Ministry's intention and that all such fears are groundless. It may well be, of course, that after the war economic conditions may make some form of assistance to the voluntary hospitals, by grants-in-aid or otherwise, necessary, but that the voluntary system will continue there is no reason to doubt.—We are, etc.,

ROBERT HUTCHISON.
HUGH LETT.
Nov. 27. W. FLETCHER SHAW.

To the Editor of the "British Medical Journal"

SIR,—The Minister of Health's scheme of reorganization for the Emergency Medical Service was announced by him in Parliament last week and published in detail in the medical press. In general he has accepted the proposals of the Central Medical War Committee as elaborated and negotiated by a special committee set up for the purpose. This special committee of the Central Medical War Committee, now known as the Advisory Emergency Hospital Medical Service Committee, includes not only members of the parent committee but representatives of the three Royal Colleges, including their Presidents, London and provincial Group Officers, and representative practitioners actually enrolled in the service.

It is, in the main, the profession's own scheme which the Minister has adopted. Its four cardinal points are:

(1) The creation of a definite establishment of whole-time, part-time, and sessional appointments.

(2) The creation of part-time appointments at £500 a year for practitioners of consultant and specialist rank.

(3) The substitution in a large number of hospitals of the payment per occupied-bed method of remunerating medical staffs for the sessional method hitherto in operation.

(4) The recognition of the Advisory Emergency Hospital Medical Service Committee of the Central Medical War Committee as the body to be consulted by the Ministry of Health on questions relating to the Emergency Hospital Service.

It is not always easy to adapt a large service to the rapidly changing conditions of war. I do, however, believe that the reorganization now being effected represents a substantial advance which is in the interest of the Government, the profession, and the community generally. As chairman of the Central Medical War Committee I commend the proposals to the profession.—I am, etc.,

H. S. SOUTTAR,
Chairman, Central Medical War Committee;
Chairman of Council, British Medical Association.
London, W.C.1, Nov. 28.

THE CAPITATION FEE IN WAR TIME

The following letter has been sent to the Ministry of Health by the Insurance Acts Committee of the British Medical Association:

Dear Sir,

It will be within the knowledge of the Ministry that insurance practitioners generally are dissatisfied with the annual capitation fee of nine shillings, which is paid for the medical treatment of each insured person. The Insurance Acts Committee has had the matter under the closest consideration, and at the outbreak of war had just completed a case in support of an upward revision of the fee. The immediate pressing claims of the war emergency arrangements have, for the moment, prevented the presentation to the Ministry of the Committee's case.

The Committee's views on the inadequacy of the present basic fee are unchanged, and its recent statistical and other investigations have confirmed these views. Without prejudice to this issue the Committee is investigating the rising cost of living and the increase in practice expenses due to war conditions in their relation to the present basic capitation fee with a view to an application for an adjustment of the fee to allow for these factors being laid before the Ministry at an early date.

Yours faithfully,
G. C. ANDERSON,
Nov. 28, 1939. *Secretary.*

INSURANCE ACTS COMMITTEE OF THE B.M.A.

MEETING OF WAR-TIME EXECUTIVE

Immediately after the outbreak of war an executive subcommittee of the Insurance Acts Committee was appointed to deal with all matters of urgency affecting the terms and conditions of service of insurance practitioners. A special meeting of this subcommittee was held at B.M.A. House on November 16 under the chairmanship of Dr. E. A. GREGG, when several matters of importance were discussed. The meeting had before it various circulars which have lately been issued by the Ministry of Health on emergency arrangements, war injury allowances, the suspension of the procedure for the issue of notices of cessation of title to medical benefit in the case of insured men called up for service, and the discontinuance of the quarterly issue of the drug tariff. A special point was made of the notification of the Ministry on September 1 to suspend until further notice proceedings in respect of failure to keep medical records. It was stated that some practitioners had interpreted this to mean that there was no longer any necessity to keep records—a very unfortunate assumption. The chairman said that that was not the meaning of the notice at all, and it would be wise to intimate to practitioners that record-keeping was just as important as ever in the war-time situation. Practitioners were, so to speak, put upon their honour in this matter.

National Service and Practitioners' Lists

Attention was drawn to the position of insured persons who have served with His Majesty's Forces or have temporarily removed from the area of the medical practitioner responsible for their treatment as insured persons. In a circular recently issued by the Ministry to insurance committees provision was made for insured persons called up under the Military Training Act, 1939, and it was felt that the principle should be extended to all insured persons engaged in national service, including those evacuated from their homes on account of the war. It was decided to urge the Ministry to restore the *status quo* in all cases.

Capitation Fee

The executive gave prolonged consideration to the question of the insurance capitation fee It had before it several resolutions from panel committees on the subject, and a memorandum presented by delegates from an open meeting of practitioners in a London area, which had urged that a war-time bonus on the present fee should be pressed for in order to meet the sharp rise in cost of living and in practice expenses. The Deputy Secretary detailed recent rises in the cost-of-living index. The executive was reminded that but for the outbreak of war the case for an increase in the basic capitation fee would already have been presented. It was felt that any application for an increase to meet temporary conditions must be without prejudice to the larger issue. The history of the capitation fee during and immediately after the last war was given. Before the war the fee stood at 7s. 3d. and remained at that figure until 1917; afterwards it rose to 8s., in 1919 to 8s. 9d., and in 1920 to 11s. after arbitration.

It was agreed, on the chairman's suggestion, to approach the Ministry, reminding them that but for the war the case for the upgrading of the capitation fee would now have been presented, and to say that without prejudice to the larger issue it was proposed to seek a temporary addition whereby the fee would be brought into relation with the rapidly growing increase in cost of living and in practice expenses.

General Practitioners and Air Raid Casualties

It was reported that the Ministry had decided to establish on a temporary basis a domiciliary medical service for all civilians who might sustain war injuries in this country and for whom in-patient hospital treatment was no longer necessary or was impracticable, treatment as out-patients being also impracticable. In this connexion the committee discussed a ruling of the Ministry that if, notwithstanding this provision of facilities for continued treatment, an insured person consulted his own doctor, any attendance and treatment required which was within the scope of general practitioners as a class would come within the practitioner's terms of service. It was decided to inform the Ministry that in the absence of experience of conditions following an air raid the committee did not accept the Minister's view that the treatment of an insured person for injuries directly attributable to such a raid was within the terms of service. It is not clear yet what the procedure is going to be with reference to the subsequent treatment of patients not seriously enough injured for detention in hospital who have been seen at first-aid posts.

Various Business

The National Pharmaceutical Union wrote asking as to the possibility of the rubber tubing of oxygen fittings being a source of infection. The committee could only reply that, of course, the possibility of infection existed in the absence of any steps to sterilize rubber tubing. The committee declined to approve various suggestions for fresh inclusions in the schedule of appliances forming part of medical benefit.

A request had previously been made to the Ministry for the inclusion of M & B 693 in the list of specially expensive drugs appended to Part II of the distribution scheme. The Ministry again stated that it was not prepared to vary its previous decision, and added: "We have on a few occasions refused sanction to special payment for an expensive proprietary drug for which we were satisfied there was a less expensive non-proprietary equivalent." The matter is one which affects only rural practitioners, and the committee decided to take it up yet once again with the Ministry, asking them to reconsider the decision from the point of view that it would be regrettable if rural practitioners were discouraged from using a drug which was considered to be of much value in treatment.

The committee had before it the letter from Dr. Douglas Robb which appeared in the *Supplement* of October 14 (p. 206) relating to those patients—chronics—to whom the doctor is permitted to issue certificates of incapacity once a month. In many such cases, the letter pointed out, the certificate is a pure formality and in peace time may not be a serious business, but during war, with the curtailment of transport for visits both by the patient to the surgery and by the doctor to the patient, it is a difficult matter. The letter suggested quarterly certificates in certain cases, and this was endorsed to some extent in a communication from a panel committee. The executive, however, did not agree with the proposal, for the reason that the period need not necessarily be the exact month, and the doctor can call on the patient at any time he happens to be passing.

Representations had been made to the Ministry on the question of pathological facilities for insured persons, but the Ministry has intimated that it does not regard the present time as a desirable one for opening up such a discussion, and it was agreed that this matter be left over for the present. It was decided to take up with a certain approved society a letter which the society had sent to a prospective member asking to be furnished with a medical certificate as to her present state of health, and adding: "As a general rule insurance medical practitioners are willing to perform a service of this kind for prospective panel patients without fee." It was considered that this remark was open to objection. A meeting of the executive of the National Defence Trust was also held.

The Secretary of State has withdrawn from Patrick Joseph Wallace, M.B., Ch.B.Irel., of Upton, near Pontefract, the authorities granted by the Regulations made under the Dangerous Drugs Act, 1920, to duly qualified medical practitioners to be in possession of and to supply any drug or preparation to which the Dangerous Drugs Regulations, 1937, or any drug to which the Raw Opium, etc., Regulations, 1937, apply. Any person who supplies Dr. Wallace with any of these drugs or preparations or supplies them on a prescription given by him will commit an offence against the Acts.

General Council of Medical Education and Registration

WINTER SESSION

The winter session of the General Medical Council was opened at the Council's offices, Hallam Street, W., on Tuesday, November 28. Sir NORMAN WALKER, the retiring President, was in the chair during the first part of the proceedings.

PRESIDENT'S ADDRESS

Sir NORMAN WALKER proceeded to deliver the following address from the chair:

At this, the 150th, session of the Council we find ourselves meeting once more with our country in a state of war. Of the thirty-five members present twenty-five years ago at the opening of the 100th session in November, 1914, at our late home at 399, Oxford Street, there are only four survivors: Sir Arthur Newsholme, Professor William Russell, and Dr. Kidd and myself, who are here to-day. Our terms of office as direct representatives, which were due to expire on January 1 next, may, I understand, be extended, in common with those of Mr. Bishop Harman and of Sir Henry Brackenbury, under an emergency Act recently passed to make provision for promoting economy and efficiency in the carrying on of our work under war conditions.

Sir Donald MacAlister, in his address to the Council on November 24, 1914, remarked that the occasion of the 100th session might in ordinary times have tempted the President to offer his reflections on the past history of the Council. He went on to say, "But these are not ordinary times. New history is in the making, day by day, for the British Empire and for the world. The Council is called upon to take an active part in meeting the national emergencies that have arisen, and will arise, in connexion with the civil and military medical services of the country." The same considerations to-day preclude the expenditure of time on recapitulation of a history which becomes constantly more interesting as it becomes longer; and I have only a few words to say about the immediate past.

The Late Chairman of the Dental Board

It is fitting that I should refer in this room and from this chair to the death of Sir Francis Dyke Acland, great-nephew of one of our most distinguished Presidents, and chairman of the Dental Board of the United Kingdom from its establishment in 1921 until May. His appointment to this position, which he filled with conspicuous ability and success, was the outcome of his work as chairman of the Departmental Committee of 1917–19 appointed to investigate the extent and gravity of the evils of dental practice by persons not qualified under the Act of 1878. On their recommendations the Bill which became the Act of 1921 and the constitution of the Board were founded. Sir Francis, who had been primarily responsible for the report of the committee, gave himself whole-heartedly to the work of the Board, as he did to everything he undertook. The public and the dental profession owe much to him, and he will leave an enduring memory here and elsewhere.

Members will wish me to offer on their behalf their most cordial congratulations to Mr. Sheridan, who has been our colleague as an additional member for dental business for ten years, and chairman of the Dental Education and Examination Committee for six, on his appointment as successor to Sir Francis. I am particularly glad to be assured that he will continue to remain with us as a colleague, for both he and Sir Francis have always been at one with me in realizing that medicine and dentistry are closely related, and that the more cordial the co-operation between the two bodies under this roof the better.

The Late Chairman of the Pharmacopoeia Commission

The British Pharmacopoeia Commission of the Council has recently suffered a very heavy loss by the death of the first chairman of the Commission, Dr. A. P. Beddard. A distinguished physician of Guy's Hospital, he revived in what might have been his years of leisure an early interest in pharmacology, and inspired and directed the work of the Commission, whose constitution was an interesting experiment, in preparing the *British Pharmacopoeia* of 1932 and the Addendum of 1936. He had the satisfaction of knowing that his unremitting labours had done much to assist the forwardness of the preparation of another issue of the *Pharmacopoeia,* which the Commission had designed to have ready for publication next year.

Members of the British Pharmacopoeia Selection Committee have been so good as to assemble at short notice in order to tender advice to the Council on the question of the succession to the chairmanship of the Commission, and their proposal, which will, I doubt not, be endorsed by the Pharmacopoeia Committee, will be laid before you at this session.

Changes in the Council

Since we met in May we have said farewell with great regret to Sir George Newman as our colleague. He had served on the Council for twenty years, and for seventeen years had been a treasurer and a member of the Executive Committee. His experience, gathered in a long career of brilliant work for the State, and the native wisdom of his advice were invaluable to the Council as a whole, to the occupants of the chair, and to other holders of office among us. For the last six years I have been happy in the knowledge that the deliberations of the Public Health Committee were guided and made fruitful by his complete grasp of the subject-matter of that great and growing sphere of medicine. Dr. Burn, the professor of pharmacology in the University of Oxford, whom I have just welcomed to the Council on his appointment as a Crown nominee in the place of Sir George, brings with him an expert knowledge which will specially assist us in relation to the *British Pharmacopoeia.*

Mr. Rilot and Mr. Woods, two of our additional members appointed by the Privy Council for dental business, were not re-elected by their constituents, and were therefore not eligible for reappointment as our colleagues after July. In their places the Privy Council have appointed an old friend, Professor Gilmour, who returns to us after an absence of fifteen years, and Mr. Cubie, whose long experience as a teacher of dentistry in Glasgow promises to be of value to the Council as well as to the Dental Board.

We all warmly congratulate Sir Robert Kelly on the knighthood conferred on him in the Birthday Honours List.

Medical Students and the War

We realize as a Council of Medical Education and Registration that the importance of maintaining due provision for study and proper requirements for qualification is enhanced rather than diminished in time of war. The numerous and difficult questions which are bound to arise in relation to the position of medical students are in the capable hands of the Licensing Bodies and of the Principals and Vice-Chancellors, who include three of our members, and arrangements have been made whereby the confusion caused twenty-five years ago by the rush of students at all stages of the curriculum to enlist will not recur. Those who have passed their examination in the preliminary sciences, and have had two terms of anatomy and physiology, are regarded as being in a reserved occupation and will continue their studies. We look with confidence to the medical schools and corporations to aid us to maintain, even in the present emergency, the standards of teaching and testing which we regard as essential to efficiency.

The problems which arose in the last war were not dissimilar, and it seems to me useful to quote from his address in November, 1914, Sir Donald's summary of the attitude of the Council:

"Communications were received from several professional authorities inquiring as to the propriety of modifying or suspending some of the existing regulations in the case of students whose regular course of study for a medical qualification might be interrupted by reason of military service. The Executive Committee thought it right to intimate, by means of a circular addressed to all the Licensing Bodies, the answer it gave in the name of the Council to the general question thus raised. In view of its importance to the public and the profession, I think it well to repeat here the words of the answer:

" ' With regard to the courses of study and examination prescribed for professional qualifications, it is the statutory duty of the General Medical Council to secure the maintenance of such a standard of efficiency as shall sufficiently guarantee the possession by candidates of the knowledge and skill requisite for the efficient practice of their profession.

" ' To this end the Council has formulated, for the guidance of the Licensing Bodies, a series of recommendations respecting such courses. These recommendations represent in general terms the *minimum* curriculum which, in the Council's opinion, should be required by the Licensing Bodies; and the Council notes with satisfaction that the Regulations of the several Bodies give effect to them.

" ' Cases may arise in which, during the present national emergency, the Bodies deem it expedient to modify or suspend the application of their regulations to particular candidates, but the Council expects that all such cases shall be duly recorded and reported to the Council in the usual way.

" ' The Council feels sure that in dealing with applications for modification or suspension of their regulations the Bodies concerned will recognize the importance, in the public interest, of maintaining unimpaired the present standard of knowledge and skill required of all who seek to be admitted to the status and privileges of registered practitioners; and will accordingly agree with the Council that it is desirable to secure, in every instance, that the requirements of the *minimum* curriculum are substantially fulfilled.' "

The Position in Australia

In my last two addresses I found it necessary to refer to certain difficulties and misunderstandings which had arisen in two of the States of the Australian Commonwealth regarding the interpretation of certain sections of Part II of the Medical Act of 1886. The outbreak of war makes it inexpedient to continue their discussion now.

We have all noted that in order to supplement the existing arrangements for collaboration between the Governments of the British Commonwealth His Majesty's Government have invited the Governments in the Dominions to send a Cabinet Minister to London to confer with Ministers here and with each other. I have long felt that a similar conference between representatives of the Medical Boards or Councils within those Dominions with which we were linked up through the application of Part II of the Act of 1886 and representatives of this Council would materially help to clear up misunderstandings which undoubtedly exist. But in the meanwhile I suggest that we should all put these difficulties into cold storage. We have never had any doubt as to the adequacy of the degrees conferred by such universities as Sydney and Melbourne, and for various periods extending over nearly half a century their graduates who desired it have been placed without question on our *Register* and endowed with all the privileges that registration carries. In return we hope that the States of Victoria and New South Wales will take the necessary steps to stay their administrative hands, and will accept the invitation to attend, when the emergency is over, the conference I have proposed. I have indeed written a personal letter to the President of the New South Wales Medical Board making this suggestion, and the letter was approved by the Executive Committee yesterday.

The Chairman of Business and I refrain on this occasion from offering you the usual forecast of the length of the session. Prophecy is not made more easy by the circumstances of the time: and we already have the certainty that by your exertions the business which awaits you will be discharged without haste and, as you will see from the programme, with even less rest than you normally enjoy.

The first item in that business will be for me to resign from the chair and for the Council, on the occurrence of a vacancy in the office of President, to elect one of their number in my place. Last Friday it was eight years since the Council were pleased to confer upon me the highest honour which is in their power to give; and three years since they were pleased to re-elect me for the period terminating at the end of the session. These eight years have been made very happy by the willing co-operation of members, past and present, and I pass from the chair with heartfelt gratitude to them all.

ELECTION OF NEW PRESIDENT

After the conclusion of Sir Norman Walker's valedictory address the General Medical Council elected as his successor in the Presidential chair Mr. Herbert Lightfoot Eason, C.B., C.M.G., M.D., M.S., F.R.C.S., who has been Principal of the University of London since 1937 and was formerly superintendent and senior ophthalmic surgeon at Guy's Hospital.

On taking the chair Mr. EASON thanked the Council for the great honour conferred on him. As a mere Englishman he hoped to be able to emulate the example of his three distinguished Scottish predecessors. In moving the Council's thanks to the retiring President, he said it was doubtful whether any member of the Council had served it with more devotion and less self-interest. He had been a member of the Council for thirty-two years; for twenty-seven years he was a member of the Executive Committee, a similar period on the Penal Cases Committee, twenty-five years on the Examination Committee, and very many years on the Business Committee. He was on the Pharmacopoeia Committee for twenty-three years, and a valued member of the committees dealing with students' registration, prevention of unqualified practice, and national health insurance. He had used his wisdom and judgment unsparingly for the benefit of the Council and the public, and without his assistance it might have made many false steps. It was with extreme regret but also with gratitude and admiration that they bade farewell to him as President.

Professor GAMGEE, seconding, said that Sir Norman Walker succeeded a great President who had been in office for years. But he had unequalled knowledge of the business of the Council and of medical examination in this country, India, and the Colonies, and he had been a worthy successor to his great predecessor.

Sir NORMAN WALKER made a brief acknowledgment, saying he had felt it a great honour to succeed Sir Donald MacAlister.

Dr. John W. Bone, treasurer of the British Medical Association, and Dr. H. Letheby Tidy were elected treasurers of the Council on a proposition from the chair, and Sir Kaye Le Fleming was, on a ballot, elected a member of the Penal Cases Committee.

MEDICAL STAFFING OF FIRST-AID POSTS

In the War Notices in the *Supplement* of November 25 (p. 227) we published the Minister of Health's reply to representations made by the British Medical Association on the medical staffing of first-aid posts. A circular which has now been issued by the Ministry to local authorities on the new arrangements states that in the more vulnerable areas a medical officer should be in complete charge of each first-aid post (including mobile units) instead of being only responsible for the training of the personnel. At present the medical officer of health is directly responsible for all the posts in his area, but it is desirable that there should be a definite link in the chain of command between him and the first-aid posts as they are now functioning.

Local authorities are asked to arrange for the medical officer at present supervising collective training at each post, or, if he is unwilling, another practitioner selected for the purpose, to undertake complete charge of the post, subject, of course, to the general directions of the medical officer of health. He would supervise not only the volunteer personnel but also the trained nurse and any members of the local authority's staff employed at the post, and he would continue to conduct the collective training of the personnel. He would also undertake the responsibility for stores and the general maintenance of the post and any correspondence on administrative matters relating to the post, so that he would, in effect, be acting as a temporary officer of the local authority. He would be expected to visit the post at least three times a week, timing his visits in such a way as to enable him to keep in touch with staff on different shifts, and to be prepared to attend during an actual air raid if required. One or more other doctors might also be retained to attend during a raid, but they would have no responsibility for the general supervision of the post.

Local authorities are authorized to pay a salary at the rate of £75 per year for each aid post in consideration of the performance of these duties, the employment being for six months in the first instance subject to a month's notice on either side. In addition, in the event of the doctor being required to attend the post owing to an actual air raid upon the locality, sessional fees would be payable at the rates announced in Circular 1869—namely, one and a half guineas for a session of not more than two hours and three guineas for a session of longer duration, subject to a total payment of not more than three guineas in respect of any one day. Further, as it is understood that on the outbreak of war medical officers were in some instances required by medical officers of health to attend their posts on a sessional basis notwithstanding the non-occurrence of raids, the payment to them of sessional fees is authorized in cases where sessional attendances were required and given before the receipt of Circular 1869. These financial arrangements are in substitution for the payment of twenty guineas already in operation, the necessary adjustment being made with the medical officers as at the date from which the change of duties comes into operation. In any case where duties on the new basis have already been performed the adjustment may be made as at the date when they started, provided that this date is later than the period for which any sessional fees are paid. In the case of first-aid posts at hospitals some modifications of the arrangements for securing responsible control of the post may be needed to suit the circumstances, provided that the cost is not increased.

Finally, local authorities are asked to inform the Minister not later than December 31, 1939, what steps have been taken to give effect to these proposals.

In the less vulnerable areas, to which this circular does not apply, the authority to pay a fee of twenty guineas per annum to one doctor at each post in respect of collective training of personnel continues in force.

Correspondence

Public Medical Services and Evacuated Persons

SIR,—In common with many other services the London Public Medical Service has had to face the problem of the large number of subscribers who are evacuees, either voluntary or under the Government scheme. The unaccompanied children are, of course, lost as subscribers "for the duration," or until their parents bring them back. But in London we have an appreciable number of subscribers who have gone away on their own account, and who, having become accustomed to insurance against the risk of a doctor's bill, are anxious to retain this advantage. The London Public Medical Service has, up to the present, told these subscribers that if, while away but still keeping up their subscriptions, they incur a doctor's bill we will pay or help to pay these bills. A considerable number of such claims have been paid, the extent of the grants being based on the National Deposit Friendly Society scale and also on length of membership. Such a plan, while convenient for a short time, is not suited for a prolonged period.

From January 1, 1940, therefore, we propose to adopt the following plan. Each subscriber who has left or proposes to leave London on account of the war and keeps up the necessary payments will be given a card to be presented to a local doctor of the subscriber's own choice. We ask such doctors to accept these subscribers for a quarterly payment of 3s. 3d. per person, which will be guaranteed and paid by us in full even if the subscriber shall cease payment during the quarter. The subscribers will be urged to select a doctor immediately on arrival and not to wait until they are ill.

This capitation fee is to cover an ordinary general practitioner service with the usual medicines. It is better than national health insurance financially, apart from there being no record-keeping or other regulations. The success of the scheme depends on the co-operation of doctors in the reception areas. It should appeal to them because Public Medical Service subscribers belong to a class which finds it difficult to meet bills. A guaranteed net payment of 13s. a year with no record-keeping or other clerical obligations is a distinctly better proposition than the chance of recovering a bill from total strangers, or the unpleasant alternative of trying to get cash payments from people who are often in very straitened circumstances.

I shall be glad to answer inquiries from other services as to our administrative procedure.—I am, etc.,

Tavistock House (South),
Tavistock Square, W.C.1,
Nov. 23.

ALFRED COX,
Secretary, Public Medical Service
for London.

Indemnity for Doctors practising Over-seas

SIR,—The London and Counties Medical Protection Society has for some years received many requests from practitioners resident over-seas that some form of indemnity should be available to them while practising outside the British Isles. Although membership of the society has at all times been open to these practitioners, the benefits accruing to them have been somewhat minimized because hitherto the society did not undertake cases for trial in colonial or foreign courts.

The council has from time to time explored the position carefully, and is now able to announce that it has succeeded in arranging, by agreement with Lloyds Underwriters, for an indemnity against actions over-seas. This indemnity will be available to members of the society on payment of an additional subscription of £2 per annum, and will be for a maximum of £1,000 in any one case or £2,000 in any one year.

Under the new scheme the society has made arrangements with Lloyds for cases to be dealt with locally after receipt of the member's application and consideration thereof by the council. Arrangements have also been made for dealing expeditiously with matters of an urgent nature.

Full details of the scheme will be sent on request to any practitioner who may be interested.—I am, etc.,

GEORGE F. STEBBING,
Chairman of Council, London and Counties
Medical Protection Society.

Nov. 22.

Car Labels

SIR,—I imagine that "M.B.," whose letter appears in the *Supplement* for November 18, is an urban practitioner, and I agree with every word he writes—for urban practitioners. But let us consider the case of the country G.P. who usually drives about fifteen hundred miles a month. He has no desire to advertise, but one car of a popular make is very like another, and the "Doctor" label on his car identifies it in the villages and he is saved a number of unnecessary return visits, much time, much very unpleasant driving after the black-out, and many gallons of petrol. This is why I personally keep these labels on both my cars.—I am, etc.,

St. Neots, Hunts, Nov. 22.
H. C. CRAVEN VEITCH.

Medical Students and Military Service

SIR,—Medical students must have passed the first professional examination and have completed two terms in anatomy and physiology to be "reserved" under the Military Service Act, while theological students, including beginners, are all "reserved." Nobody wishes to claim priority for medical students, but surely they should have equal rights with theological students.

As a past chairman of a large division of the B.M.A. and vice-chairman of the Local Emergency Committee I feel this is a matter which the B.M.A. should try and rectify, as it concerns the sons of many of their members who have given them a liberal and costly education in the hope that they will eventually succeed to their fathers' practices. I would suggest that a medical student who has passed his first professional examination should at least be "reserved." In a very short time these students will be qualified to act as dressers or surgeon probationers as in the last war. If the war should last long enough they will be fully qualified, whereas as things now are they may never have the opportunity to carry on their studies.

I have discussed this matter with many members of the profession, including teaching staffs of hospitals, and all of them are of the same opinion, but so far no one apparently has made the suggestion openly.—I am, etc.,

Nov. 20. ALPHA.

Naval, Military, and Air Force Appointments

ROYAL NAVAL VOLUNTEER RESERVE

Probationary Surgeon Lieutenants to be Surgeon Lieutenants with seniorities as indicated in parentheses: F. J. Curtis (August 5, 1938); D. C Brodie (October 5, 1938); H. Stirling (October 7, 1938); P. A. T. Phibbs (October 19, 1938); J. F. Foulkes (October 3, 1938); J. A. Chivers (October 18, 1938); J. R. H. Peat (April 20, 1938).

ROYAL ARMY MEDICAL CORPS

The precedence of Captain W. G. Macfie is next below Captain J. B. Dancer and not as stated in the *London Gazette* of October 17, 1939.

The following short-service officers have been appointed to permanent commissions, retaining their present seniority: Captains K. H. Clark, J. A. D. Johnston, M.C., W. M. Oxley, W. G Greene, R. H. Hunt, A. J A Gray, G. M. Denning, J. O'Connell, and H H Atkinson

The probationary commission of Lieutenant W. U. Hill has terminated

ROYAL AIR FORCE RESERVE. MEDICAL BRANCH

Flying Officers A. R. Sibbald and E. A. Mayston to be Flight Lieutenants

AUXILIARY AIR FORCE: MEDICAL BRANCH

Flying Officers E. C Gross, A. C. Hendry, M.C., and R. S Cromie to be Flight Lieutenants.

ROYAL AIR FORCE VOLUNTEER RESERVE: MEDICAL BRANCH

Flying Officers T. Crowley, B. Haring, C. H. Levick, C. F. H. Sergeant, G. F Rees-Jones, and R. F. Stubbs to be Flight Lieutenants.

Flying Officer B. M. Merriman has relinquished his commission on account of ill-health

REGULAR ARMY RESERVE OF OFFICERS

ROYAL ARMY MEDICAL CORPS

Major F. A. Robinson, M.C., has ceased to belong to the Reserve of Officers on account of ill-health

Captain A. J. Horne has ceased to belong to the Reserve of Officers on account of ill-health.

Lieutenant A. H. W. Fleming, from Reserve of Officers, Royal Norfolk Regiment, to be Lieutenant, with seniority July 31, 1925. (Substituted for the notification in the *London Gazette* of October 24.)

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel D. W. Boswell, T.D., has relinquished his commission on ceasing to be employed

Captain C. B. Macleod to be Major.

Captain E. D. Fitzpatrick has relinquished his commission on account of ill-health.

Captain A D. Forgie has resigned his commission

Captain R. Cunningham, from Territorial Army Reserve of Officers, R.A M.C., to be Captain.

Lieutenant C. W. Gordon to be Captain, with seniority July 8, 1938.

Lieutenant E. F Baines, from Territorial Army Reserve of Officers, R A.M C., to be Lieutenant.

Lieutenant H. W. Wykes, from Territorial Army Reserve of Officers, Royal Artillery, to be Lieutenant

Lieutenant I. M. Davidson has relinquished his commission on account of ill-health.

Second Lieutenant A. Cierar, from Royal Artillery, Territorial Army, to be Captain, with seniority February 10, 1938.

O. J. Morgan to be Lieutenant.

TERRITORIAL ARMY RESERVE OF OFFICERS: ROYAL ARMY MEDICAL CORPS

Major J. R. Menzies has relinquished his commission on account of ill-health.

Captain G S. Lewis has relinquished his commission on account of ill-health.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

Lieutenant T B Bailey has relinquished his commission on account of ill-health.

To be Lieutenants: H. G. John, A. V. J Russell, S. B. Greenberg, J S. Banks, H. W. Cowan, A. E. Cooper, J. Gendle, H M. R. Knight, A. D McGill, J. C. Reid, G. F. Boyle, J. A. Barrie, J Hendry, D. S. Crawford, D W. Forgan, J. Hesketh-Beasley, H. A. Vickers, G. R. Royston, J. D. Gordon, L. F. McWilliams, W. S. Terry, J. S Maxwell, D. C. Williams, F G. Macdonald, Q. F. Evans, R. M. Scott, A. S Beer, D. D. S Stewart, E. B. Brennan, P. J. McManus, J. S Marr, J. H O. Chance, T. Duffy, C Nairnsey, B. T. Jones, A W. O. Taylor, H. M. Brown, K. McD. Ross, W. J. Walter, H. R. Kellas, A. C. D. Parsons, D C. Tomlins, D. S. P. Wilson, J. M. Bassett, R. D Rowlands, C. J. Wells, I. H. Baum, N. A. Scott, R. M. B. MacKenna, R. W Eason, W. H. de B. Hubert, C. E. H. Maycroft, T. E. Tierney, F. H C. Watson, R. W. Farquhar, R.-F.-K. Webster, L. B Wevill, H. R. Davies, J. J. Elphinstone, D. F. Laing, R. S. MacHardy, I. Thomas, R. A. Brown, P G. McGrath, W. D. Moore, P. W. H. Bleasdale, J. S. Kinnear, T. A. S. Brown, V. W. J. Hetreed, J. H Moir, R. J. D. Temple, J. C. Morris, J. A M. Paton, G. W. Robinson, J. D. Watson, H. W. Allen, J. M. Jackson, C. C. S Pike, E. Townsend, G. M. Cooper, C. M. Wells, A. J. May, R M. Shaw, D. Levine, A. B. Wilkes, R. E. Isaac, A. Mackler, J. I. Heany, J. B. Hurll, M. J. Lahiff, P. W. M Martin, J A. Robson, J. L D. Williams, L. J. J. O'Donnell, F. O'Driscoll, I. S. Schalit, M W. Smith, T. H. W. Clarke, S B. Hughes, J. McCurdy, R. B. G. Robertson, G. C. Haslam, D. L. Stewart, P. S Adler, E. S. A. Ashe, A Burns, W A. Dunnet, J. R. Heming, I. Jacobson, E J. Ryan-McMahon, A Macnab, F. A Evans, H L. Ellis, J. N. T. Hulton, J. E. Wooding, L. C. Allan.

Postgraduate News

The Fellowship of Medicine announces a course of instruction for F.R.C.S. (Final) candidates, to be given as follows: surgical tutorial classes, twice or three times weekly at 4.30 p.m., from December 12, 1939, to January 25, 1940. The lectures will be given at the lecture room of the Medical Society of London. A comprehensive course, including clinical instruction, in the wards and out-patient department, lectures, *x* rays and museum demonstrations, and tutorial classes (including answering set questions). The course will be given from December 11, 1939, to January 27, 1940, from 9.30 a.m. to 1 p.m. Mondays to Fridays, and 11 a.m. to 1 p.m. on Saturdays. Short courses in pathology will also be given, each consisting of two demonstrations (in the same week) from 2 p.m. to 3.30 p.m., and limited to six postgraduates. The course will be repeated (for fresh classes of six postgraduates) if there is sufficient demand. No postgraduate may attend more than one course.

The committee of the South-West London Post Graduate Association has decided that owing to the war no meetings should be held until further notice. The position will be reviewed in March, 1940. It is understood that members of the association will be welcomed as visitors at the meeting of the South-West London Medical Society held at Bolingbroke Hospital on the second Wednesday in the month at 3.30 p.m.

WEEKLY POSTGRADUATE DIARY

FELLOWSHIP OF MEDICINE AND POSTGRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street. W.—*Brompton Hospital, S.W.*: Mon. and Wed., 4.30 p.m., M.R.C.P. Course in Chest Diseases.

MANCHESTER ROYAL INFIRMARY.—First of course of six lecture-demonstrations on first-aid treatment of air raid casualties. *Tues*, 3 30 p.m., Prof. H. Platt, Fractures of Limb Bones and Injuries to Joints, Simple and Compound. *Fri*, Mr. W. R. Douglas, (*a*) Shock and Resuscitation of Shocked Patient; (*b*) General First-aid Treatment of Wounds, Burns, etc.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

General Meeting of Fellows—Tues., 2 p m. Ballot for election to the Fellowship.

Section of Orthopaedics—Tues., 2.30 p.m. Short papers by Mr. C. Lambrinudi: A Further Use of Kirschner Wires. Mr H. Jackson Burrows: Treatment of Ununited Fractures by Bone-grafting without Resection of the Bone Ends. Miss M. Forrester-Brown: Simplification of Technique in some Joint Operations.

Section of History of Medicine.—Wed., 2 30 p.m. Paper by Dr. George Edwards: Philip Syng Physick (1768–1837)

Section of Neurology.—Thurs., 2 p m. Paper by Dr. J. W. D. Bull: Subdural Haematomas.

BIOCHEMICAL SOCIETY, Courtauld Institute of Biochemistry, Middlesex Hospital, W.—Saturday, December 9, 11.45 a.m. Communications and demonstrations.

ROYAL INSTITUTION, 21, Albemarle Street, W.—*Tues.*, 2 30 p.m., Sir Frederick Keeble, F.R.S., Food Production in War Time.

VACANCIES

EXAMINING FACTORY SURGEON.—The appointment at Newport (Monmouthshire) is vacant. Applications to the Chief Inspector of Factories, Home Office, Whitehall, S.W.1, by December 11.

APPOINTMENTS

JONES, David J., B.Sc., M.B., D.P.H. (Medical Officer of Health, North Breconshire Combined Districts), Assistant County Medical Officer of Health for Northamptonshire, and District Medical Officer for Brackley Borough, Brackley Rural District, and Brixworth Rural District.

OWEN, L. C. P., M.R.C S., L.R.C.P., Resident Assistant Medical Officer, Brighton Municipal Hospital, Brighton.

ROCHE, Alex. E., M Ch., F.R.C.S., Genito-urinary Surgeon, West London Hospital, Hammersmith Road, W.

EXAMINING FACTORY SURGEONS.—J. A. R. Cant, M.B., Ch.B., for the Coleshill District (Warwickshire); Dominic Ciantar, L.R.C.P. and S., L.R.F.P.S., for the Abercrave District (Breconshire).

B.M.A.: Branch and Division Meetings to be Held

METROPOLITAN COUNTIES BRANCH: CITY DIVISION.—At B.M.A. House, Tavistock Square, W.C., Tuesday, December 5, 2.45 p.m. Dr. J. Trueta: "The Medical and Surgical Assistance of Minor Injuries in Bombarded Towns."

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this heading is 9s This amount should be forwarded with the notice, authenticated by the name and address of the sender, and should reach the Advertisement Manager not later than the first post Tuesday morning to ensure insertion in the current issue.

MARRIAGE

MCKENNA—MCMAHON.—On November 10, 1939, at St. Gertrude's Church, South Croydon, D J McKenna, Larne, Co Antrim, to Aileen McMahon, M R.C.S., L.R C P., D.P H., 10, Normanton Road, South Croydon.

WAR NOTICES

The Emergency Medical Service

The following letter has been sent by the Ministry of Health to all voluntary hospitals in the Emergency Hospital Scheme. It is of particular interest to the staffs of those voluntary hospitals in the Emergency Medical Service to which no whole-time member of the service undertaking clinical work (other than a house officer) is attached—that is, to the staffs of the majority of provincial hospitals.

"1. I am directed by the Minister of Health to inform you that he has agreed with the Advisory Emergency Medical Service Committee set up by the Central Medical War Committee to make certain changes in the method of payment for medical services at voluntary hospitals within the Emergency Hospital Scheme where medical attendance on casualties has hitherto been provided for on a sessional basis and by the payment of sessional fees.

2. At voluntary hospitals to which are attached whole-time members of the Emergency Medical Service undertaking clinical work (other than house officers) or members of the service receiving a part-time salary or retaining fee the sessional arrangements will continue in operation.

3. To all other voluntary hospitals within the Emergency Hospital Scheme the Minister will make payments at the rate of 1s. 6d. per night per bed occupied by a casualty and of 6d. per casualty out-patient attendance, by way of an addition to the fortnightly interim payments being made to the hospitals under existing arrangements. These sums will be paid on condition that they are devoted to the payment of the medical staff employed on the casualty work in such manner as the medical staff may desire. The memorandum accompanying the fortnightly payment will specify separately the amount paid for medical services and will show how it has been calculated. It will be appreciated that the payment for a given fortnight is based on the last return due before the commencement of that fortnight.

4. If and when the arrangements for medical staffing at a hospital are changed the corresponding change will be made in the method of payment for medical services. In no case will the methods of payment for these services by sessions and by occupied beds be in operation at the same hospital for the same period.

5. The term 'casualty' in this circular includes any of the types of cases for which the Government accepts financial responsibility as if they were casualties, as indicated in the fortnightly returns rendered by hospitals to the Ministry. These returns, subject to the necessary scrutiny, will be used for the purpose of calculating the amounts payable for medical services.

6. In the case of a voluntary hospital (not covered by paragraph 2), where medical services have already been rendered for these types of cases and no payments have yet been made, it is proposed to make the new method of payment retrospective. Subject to this the change will take effect as from December 1."

Unaccompanied Children Schemes

The time is approaching when practitioners in reception areas will be expected, under the arrangements made by their Local Emergency Committees, to make certain returns in order to secure that appropriate payment is made to them. Such practitioners are asked to study the arrangements made by their Local Emergency Committees and to make the necessary returns at the prescribed time. Any practitioner in a reception area who is unaware of the detailed arrangements should communicate with the secretary of the Local Emergency Committee.

Reorganized Emergency Hospital Service

The description of the reorganized Emergency Hospital Medical Service published in the War Notices in the *Supplement* of November 25 (p. 227) contained a statement that "the position will be reviewed in the light of experience for the period ended June 30, 1940." This statement related only to the daily rate of payment per occupied bed of 1s. 6d. a day and to the rate of payment of 6d. per out-patient attendance applicable to those hospitals in which no Class I officers (other than administrative or house officers), or Class II officers, or Class III officers are employed. It should not be read, as it has by some, as meaning that the terms of service generally will be reviewed for the period ended June 30, 1940.

CENTRAL EMERGENCY COMMITTEE
(Central Medical War Committee),
British Medical Association House,
Tavistock Square, W.C.1.

INSURANCE PRACTITIONERS AND AIR RAID CASUALTIES

The following communication, in which it is urged that treatment of air raid injuries should be regarded as outside the scope of medical benefit under national health insurance, has been forwarded by the British Medical Association to the Ministry of Health:

"In a letter dated July 10, 1939, the Ministry stated that it was the intention of the Government to provide persons injured in air raids with treatment at the public expense at first-aid posts and at hospitals.

It is understood to be the view of the Ministry that if an injured insured person decides not to avail himself of these facilities and consults his insurance doctor any attendance and treatment required which is within the competence of the insurance practitioner would come within the practitioner's terms and conditions of service under national health insurance. Under the arrangements for the continued medical care by their general practitioners of civilians who sustain war injuries and whom it is no longer necessary or practicable to treat as an in-patient, or whom it is not practicable to treat as an out-patient, the insured persons falling within this group are held by the Ministry to be entitled to medical care under national health insurance Thirdly, in a communication dated October 21, 1939, relating to the areas not covered by first-aid posts, mobile or fixed, the Ministry ruled that only in the case of uninsured persons would the Ministry consider remunerating practitioners for the work done in treating air raid casualties.

In general the Insurance Acts Committee does not accept the Ministry's view that persons injured in air raids and requiring general practitioner treatment either early or late in respect of the injuries they sustain are entitled to receive such treatment at the hands of their insurance practitioners within the normal national health insurance arrangements. There are a number of considerations which lead it to take this view:

(1) When the existing capitation fee was decided upon it was not contemplated that such unusual services would be required, and no financial recognition of them was taken into account in assessing the capitation fee.

(2) For other purposes within the scope of national health insurance, notably for purposes of cash benefits, insured persons

injured in air raids are *not* regarded as covered by the peace-time national health insurance arrangements

(3) It has been agreed by the Ministry that first-aid treatment rendered in road accidents to insured persons does not fall within the scope of medical benefit. Thus, on the basis of the existing decisions if an insured person is injured in a road accident his treatment is outside the scope, but if he is injured as a result of an air raid his treatment is within the scope.

(4) The Government has deemed it necessary to provide, at the public expense, special services for this range of medical work. It is illogical that at the same time it should rule that where an insured person does not desire to use these services or, as may well happen. these services are inadequate for the purpose, or, in certain rural areas, non-existent, the Government should shift the responsibility on to insurance practitioners.

(5) The following is an extract from the report of the official *British Medical Journal* reporter of the meeting of representatives of Local Emergency Committees addressed by the Minister of Health on February 15, 1939:

> 'In reply to a question as to whether he could give an assurance that attendance on air raid casualties would not form part of medical benefit under the present terms of service for insurance practitioners, he [the Minister] replied, "I think I can give that assurance. I am sure that will fall outside national health insurance."'

In the view of the Insurance Acts Committee the only consistent and equitable policy to adopt would be to regard air raid injuries, like those received in road accidents, as outside the scope of national health insurance. The Ministry has admitted the principle by providing facilities for the population, insured and uninsured, at the public expense, and by making non-insurance provision for cash payments. To recognize that insured persons who so choose are free to obtain an alternative service at the expense not of themselves but of the time and labour of insurance practitioners, who are in receipt of a capitation fee not including provision for this unusual work, is unfair to insurance practitioners. It is unlikely to encourage either the proper use of the facilities provided at the public expense or, where this is necessary, any augmentation required to make them reasonably complete.

What is urged is that the Ministry should exclude treatment of air raid injuries from the scope of national health insurance, requiring insured persons and others in areas where sufficient facilities do exist either to avail themselves of the national facilities or to obtain medical service at their own expense; in areas where facilities do not exist the official arrangements should permit insured persons and others to obtain the service they need through the only local channel available, the medical profession of the area, in this case at the public expense."

GENERAL MEDICAL COUNCIL

WINTER SESSION

The unusual procedure was followed at the meeting of the General Medical Council on November 29 of taking all the committee reports *in camera*. These included reports from the Examination, Public Health, and Pharmacopoeia Committees. The last-named report was afterwards issued to the Press, and an abstract appears below.

Professor J. H. Burn was appointed to the Examination Committee in place of Mr. H. L. Eason, the new President, and to the Public Health Committee in place of Sir George Newman, retired.

Messrs. Waterhouse and Co. were reappointed solicitors to the Council.

The British Pharmacopoeia

Dr. David Campbell, chairman of the Pharmacopoeia Committee, reported to the Council that the work of revising the *British Pharmacopoeia* was so far advanced that but for the war the next publication would have been in 1941. The date of publication must now be modified. Costs of printing and paper make it undesirable to publish the book in war time, and, moreover, many objections could be raised to the publication of a set of new standards at a time when trade conditions are disturbed and supplies are difficult.

During the last war numerous problems relating to drugs and their pharmacopoeial standards arose, and in some instances it became necessary to deal with the problems by modifying the *British Pharmacopoeia*. This time, fortunately, the Council has the expert advice of the Pharmacopoeia Commission on any problems of this kind which may arise. Contact has been made between the Commission and the Ministries of Health and of Food. The Medical Research Council has formed a Therapeutic Advisory Subcommittee to advise the Ministry of Health and the medical and pharmaceutical professions on the relative therapeutic importance of drugs and on economy in their use. The secretary of the Commission, Dr. C. H. Hampshire, has been appointed secretary of this subcommittee.

The Commission is already in co-operation with the Association of British Chemical Manufacturers. A subject which is being actively taken up is the official naming of British substitutes for foreign proprietaries and the inclusion of the names in the *British Pharmacopoeia*. Monographs on British equivalents are in preparation, and should the need arise the Commission proposes to ask the Council at a later stage to sanction an issue of an addendum to the *British Pharmacopoeia* containing these monographs.

The appointment of Professor J. A. Gunn as chairman of the British Pharmacopoeia Commission in the place of the late Dr. A. P. Beddard was made on the recommendation of a Selection Committee. Professor Gunn, who has been a member of the Commission ever since its formation, is professor of therapeutics (formerly professor of pharmacology) in the University of Oxford and director of the Nuffield Institute for Medical Research.

Restorations

It was announced that the Council had restored the following names to the *Medical Register*: Patrick Joseph O'Shaughnessy, Douglas Chetham Pim, Frederick Arthur Pring, and David West.

The following were restored to the *Dentists Register*: Hubert Lancelot Terry Bramley, John Herdman Faulding, Michael Henry Harte, and James Sharples Hopwood.

DISCIPLINARY INQUIRIES

Cases Postponed from Previous Sessions

The Council further considered the case of Ewen Lovat Fraser, registered as of Armley Road, Leeds, against whom two convictions, one in 1934 for being in charge of a motor car whilst under the influence of drink, and the other in 1939 of driving or attempting to drive a car whilst under the influence of drink, had been proved at the May session. Mr. Oswald Hempson, for Dr. Fraser, brought forward excellent testimonials from some professional colleagues and others to Dr. Fraser's character, and said that he deeply regretted his fault. The Council decided not to instruct the Registrar to erase the name.

The case of Arthur Appleton Woods, registered as of Charles Street, Hanley, against whom two convictions, in 1938, of being in charge of a motor car whilst under the influence of drink had been found proved at the previous November session, came up for judgment. Testimonials in Dr. Woods's favour were read from three medical colleagues and a clergyman. In this case also the Council did not see fit to erase the name.

The next adjourned case was that of John McGhee, registered as of Station Road, Galston, Ayrshire, against whom at the last November session it had been proved that he had been convicted in 1938 of driving a motor car whilst under the influence of drink. Testimonials in Dr. McGhee's favour were read from two medical men, and Dr. McGhee told the Council that, having promised on the last occasion to practise total abstinence, he had faithfully fulfilled his promise and intended to continue to do so. The Council decided not to erase the name.

A different course was taken with the remaining adjourned case, that of William Aloysius Kennedy, registered as of Gower Street, Glasgow, against whom it had been proved at the November, 1937, session that on three occasions in 1937 he had been convicted, once of being drunk and disorderly, and twice of being in charge of a motor car whilst under the influence of drink. Judgment was postponed in the first instance for one year, and on Dr. Kennedy's reappearance in November, 1938, he was told by the Council that it was not satisfied with the testimonials he had produced, and judgment was further postponed for six months. At the May, 1939, session Dr. Kennedy did not appear, and the Council again adjourned the case for six months, and desired to intimate to

Dr. Kennedy its strong advice that he should be present on the next occasion. Dr. Kennedy now appeared in answer to his notice. The Council's solicitor read various testimonials which had been received from doctors to whom Dr. Kennedy had acted as locumtenant and from a shipping company, in whose employment he had been as a ship surgeon. Asked whether he had anything to say to the Council, Dr. Kennedy replied that he had not, and after consideration *in camera* the Council directed the Registrar to erase the name of William Aloysius Kennedy from the *Register*.

Misdemeanours : New Cases

The Council considered the case of Robert Campbell Crawfurd, registered as of Brundholme House, Keswick, who was charged with having been convicted at the Sheriff Court of Edinburgh, in March, 1937, of driving a motor car without due care and of driving the same car whilst under the influence of drink to such an extent as to be incapable of exercising proper control, and in September, 1939, of a similar offence, on which latter occasion he was fined £40 or three months' imprisonment. The Council's solicitor said that after the first conviction, in 1937, a warning was addressed to Dr. Crawfurd from the Registrar, to which he replied expressing regret for a temporary lapse. On the second occasion, in 1939, two special constables saw him on the footway, and, forming the opinion that he was drunk, took him to the police station. He was not driving the car.

Dr. Crawfurd said that he served for four years in the R.A.M.C. during the last war, and was sent home with malaria and dysentery. After demobilization he joined his father in practice at Keswick, but in February of this year he had to give up practice entirely owing to poor health, and he went to live with his father, who had in the meantime retired, at Edinburgh. His father and mother both died within a short time, and these events affected him considerably, and it was his depression consequent upon bereavement which accounted for the incident giving rise to the second conviction. On neither of these occasions was any harm done to any member of the public, and both were in Edinburgh, where he had never practised. He promised to abstain from alcohol in future.

Mr. A. Pereira, on behalf of Dr. Crawfurd, put in testimonials by two medical men who wrote as to Dr. Crawfurd's integrity during his practice in Keswick.

After deliberation, the Council did not see fit to erase Dr. Crawfurd's name, and closed the case.

The case next considered was that of Joseph Marshall McCaldin Wright, registered as of The Lodge, Southborne Road, Bournemouth, who appeared on the charge that he had been convicted, in March, 1939, at Romsey police court, of being under the influence of drink whilst driving a motor car and of driving a motor car dangerously, and on the following day, at Bournemouth police court, of being in charge of a motor vehicle whilst under the influence of drink to such an extent as to be incapable of having proper control.

The Council's solicitor said that on the evening of March 14 a police constable saw a stationary motor car and found the respondent in it with his head resting on the wheel. When he got out he was unsteady on his feet, and a police surgeon said that he was drunk. Instead of appearing at the police court next day as he had undertaken to do, he again went out in his car and collided with another car, though without injuring any of the occupants. This was the offence for which he was summoned at Romsey, and a doctor testified that his gait was unsteady and his speech not normal, and also said that he was not fit apart from alcohol, and that a small amount would have a disproportionate effect upon him. On the following day he appeared at Bournemouth to answer the earlier charge. There the magistrates bound him over, and he agreed to abstain from intoxicating liquor and to be under the care of Dr. Watson Smith of Bournemouth for three months.

Dr. Wright, in evidence, said that he had practised in Bournemouth for nearly five years. He was extremely tired and worried on the evening of March 14, and was at the time recovering from an attack of influenza for which he had not laid up. Two years previously he had had pneumonia with an abscess in the lung and was ill for four months. Asked why he did not go to Bournemouth police court on the day on which he was summoned, he said that he set out to go, but on the way he felt "panicky" about the publicity which the case might receive and drove his car in another direction, which led to the second incident. He had since been under the care of Dr. Watson Smith for three months, during which time he had not practised, but he was now back again in harness.

A statutory declaration by Dr. Watson Smith was read in which he said that he had known the respondent since he came to Bournemouth, and had formed the opinion that he was a good and conscientious doctor. On the day of the offence he had been on duty for many hours, attending various calls, and had taken little or no food. He had been suffering from what appeared to have been influenza about a fortnight previously, and had post-influenzal depression. He was a man engaged in busy general practice and well respected by his colleagues in the profession. Statutory declarations were also read from another Bournemouth practitioner and from a clergyman, both speaking of Dr. Wright in the highest terms.

The Council did not see fit to direct the Registrar to erase the name.

The Council proceeded to the consideration of a charge against Arthur Patrick Kennedy, registered as of Newbridge Street, Wolverhampton, that in June last he was convicted at the Chester assizes of the following misdemeanour, namely, of conspiring with other persons unlawfully to procure the miscarriage of two women, and was sentenced to eight months' imprisonment.

The Council's solicitor, in outlining the facts, said that in November, 1938, a woman, suspecting herself to be pregnant, went to see Dr. Kennedy, to whom she was introduced by a man friend. Dr. Kennedy made arrangements for her to go to Crewe, where she was met by a woman who took her to a house and performed an illegal operation upon her. After the operation she stayed for some time at another house in Crewe, and when she was well again Dr. Kennedy himself drove her home. The man friend stated in evidence at the assizes that he paid Dr. Kennedy ten guineas. In the case of another woman in February, 1939, it was alleged that similar arrangements were made, an illegal operation being again performed by the same woman who had performed the first, but at another house. The payment was said to have been £5. Dr. Kennedy was charged jointly with the woman who had performed the two operations and with two other women at whose houses they had been done. One of the women was convicted on twenty-two charges, and another on six, but Dr. Kennedy's name was only mentioned in connexion with these two. At the trial Dr. Kennedy's counsel had said that there was no case to go to the jury, but the judge had overruled this. The jury had found him guilty on both charges, and the judge in passing sentence had said that he agreed with the verdict, and with that verdict went Dr. Kennedy's career. "If I punish two ignorant women, what can I say to an educated man who knew the terrible risks which were being run?"

Dr. Kennedy appeared before the Council, with Mr. Vincent Matthews, solicitor, who said that his client did not seek to dispute the conviction, but there were certain dissimilarities from the ordinary "procuring miscarriage" case. The man who was associated with the first woman was a personal friend of Dr. Kennedy and the doctor's better judgment was overridden by his friend's persuasions, though in law he knew that that was no mitigation. In the other case the girl concerned threatened to commit suicide, and here again the doctor was "more of a fool than a knave." Dr. Kennedy was 55 years of age, a married man with six dependent children, and so highly respected that a petition had been got up locally and signed by 4,000 people appealing to the Council to treat the case leniently. This was not a case of a professional abortionist, and the doctor himself did not take an active part in procuring abortion. Asked by the President whether Dr. Kennedy had received any money, Mr. Matthews replied that he did not think he had made any profit at all; the money had been paid to some of the others.

After consideration *in camera* the Council found the conviction proved and instructed the Registrar to erase the name of Arthur Patrick Kennedy.

Adultery with a Patient

The final case was that of George Holman, registered as of Dover House Road, Roehampton, who appeared on the charge of having committed adultery with Olive May Dunand, a married woman, of which adultery he had been found guilty by decree of the Divorce Court dated November 8, 1938, and made absolute on May 15, 1939, in the case of Dunand *v.* Dunand and Holman in which he was the co-respondent, the said Olive May Dunand, her husband, and family having been patients of his at all material times.

Dr. Holman was present and was legally represented by Mr. Thomas Carthew, K.C., on behalf of the London and Counties Medical Protection Society.

The Council's solicitor read the transcript of the Divorce Court evidence. The evidence given by Mr. Ernest Lennox Dunand, the husband, was to the effect that he first met Dr. Holman when he attended his wife at the birth of their second daughter, and Dr. Holman continued to be medical attendant to the family for many years, down to the early part of 1938. The two families became friends, and went to bridge parties at one another's houses. Early in 1934 Mr. Dunand noticed a change in his wife, who was then seen with the co-respondent from time to time. In 1935 she had a serious operation, and when her husband visited her at the nursing home she seemed indifferent to him. This feeling made itself more evident on her return home, and he spoke about it to Dr. Holman, who told him not to worry her. In 1936 she suggested a separation, to which he would not agree. Later he spoke again to the doctor about differences between his wife and himself, but the doctor told him to leave his wife alone. In another conversation the husband said that he thought the cause of the trouble was the wife's infatuation for the doctor and asked him not to see her so much. Eventually observation was kept on the movements of the respondent and co-respondent, and it was discovered that the doctor rented a flat which they visited, though they were careful not to be seen going there together. Thereupon the divorce proceedings were taken. It was admitted that professional relationship existed at all material times.

Mr. Carthew, on behalf of Dr. Holman, said that, having considered the matter, as there were no facts in dispute, he did not think it would be proper to waste the time of the Council in calling Dr. Holman. He added that Dr. Holman had married the lady as soon as the divorce was made absolute. Dr. Holman had been qualified for thirty years, and there had never been any complaint about his conduct in the past. He begged the Council to give the fullest consideration to the ameliorating features of the case.

Four statutory declarations in which the character of Dr. Holman was spoken of in high terms were put in by Dr. C. R. Box and Mr. Peter L. Daniel of London, Dr. Montague Rust, and Dr. S. W. H. Moul (Dr. Holman's partner).

After a consideration *in camera* the Council found the facts alleged against Dr. Holman in the notice of inquiry proved to its satisfaction, judged him to have been guilty of infamous conduct in a professional respect, and instructed the Registrar to erase his name from the *Medical Register*.

Correspondence

House Officers and the E.M.S.

Sir,—At this time when the Emergency Medical Service is being reorganized I should like to bring to more general notice certain anomalies in the position of the resident house officers in the special hospitals. I am a house-surgeon in a well-known London eye hospital which has a first-aid post in the basement staffed by outside personnel but which is apparently not otherwise recognized as an emergency hospital. I and my fellow-residents have not been recruited into the E.M.S. despite the fact that we are working under an ophthalmic surgeon who is a whole-time officer in this service. I understand that our colleagues in other special hospitals are in a similar position.

In the course of our routine work here we are daily treating A.R.P. workers, police, members of H.M. Forces, etc., as well as school children normally cared for by the L.C.C., and the usual civilian population. In the event of air raids on London I cannot see that our specialist services will be any less valuable. From recent articles and letters in the *Journal* it would seem that the eye is no less vulnerable than any other organ of the body to enemy action. It is not difficult to envisage the stream of eye casualties with which we should have to deal in the event of a serious air raid (*vide* the paper by Colonel A. Irvine-Fortescue in the *Journal* of October 28 (p. 846)). Since we house-surgeons have no official position in the E.M.S., what is to be our attitude to these patients? Should we leave them all to the one surgeon here who is an officer in the E.M.S. or should we perhaps direct them to the first-aid post for treatment by relatively unskilled hands? Obviously we should have to help: but why should we not do so officially as members of the E.M.S.?

I have several friends, qualified as recently as this year, and yet holding appointments in the E.M.S. in various general hospitals. Most of us in the special hospitals have already held house appointments in general hospitals and have spent some years in addition in the study of our special branch. Many of us hold higher degrees or diplomas. Is it too much to hope that we will be given at least an equal status with our junior colleagues of the general hospitals when the reorganized Emergency Hospital Medical Service finally comes into being?—I am, etc.,

London, Nov. 25. W. Kennedy Smiley.

Postgraduate News

The Fellowship of Medicine announces the following courses of instruction for Final F.R.C.S. candidates: (1) surgical tutorial classes, twice weekly, 4.30 p.m., December 12, 1939, to January 25, 1940, at the Medical Society of London, 11, Chandos Street, W., the first two lectures of which will be on herniae by Mr. R. J. McNeill Love, on December 12, and on intestinal obstruction by Mr. T. Meyrick Thomas, on December 14; (2) a comprehensive course at the Royal Cancer Hospital, from December 11, 1939, to January 27, 1940, daily from 9.30 a.m. to 1 p.m., including clinical instruction in the wards and out-patient department, lectures, *x*-ray and museum demonstrations, and tutorial classes (including answering set questions); (3) short courses in pathology will be given in January, each course consisting of two demonstrations (in the same week), from 2 p.m. to 3.30 p.m., and each course limited to six postgraduates.

WEEKLY POSTGRADUATE DIARY

British Postgraduate Medical School, Ducane Road, W.—*Daily*, 10 a.m. to 4 p.m., Medical Clinics, Surgical Clinics and Operations, Obstetrical and Gynaecological Clinics and Operations. *Daily*, 1.30 p.m. to 2 p.m., Post-mortem Demonstration. *Tues.*, 2.30 p.m., Lord Horder, Ward Clinic. *Wed.*, 11.30 a.m., Clinico-pathological Conference (Medical); 2 p.m., Prof. Dible, The Pathology of Some Bone Diseases; 3 p.m., Clinico-pathological Conference (Surgical). *Thurs.*, 2 to 4 p.m., Dr. Duncan White, Radiological Conference. *Fri.*, 2 p.m., Clinico-pathological Conference (Gynaecological).

Fellowship of Medicine and Postgraduate Medical Association, 1, Wimpole Street, W.—*Royal Cancer Hospital, S.W.*—Mon. to Fri., 9.30 a.m. to 1 p.m.; Sat., 11 a.m. to 1 p.m. Comprehensive Final F.R.C.S. Course. *Medical Society of London*, 11, Chandos Street, W.—Surgical Tutorial Classes, Tues., 4.30 p.m., Mr. R. J. McNeill Love, Herniae; Thurs., 4.30 p.m., Mr. T. Meyrick Thomas, Intestinal Obstruction. *Royal College of Surgeons of England*, Lincoln's Inn Fields, W.C.—Tues. and Wed., 2 p.m. to 3.30 p.m., F.R.C.S. Pathology Course. (*Strictly limited.*) *Brompton Hospital, S.W.*—Mon. and Wed., 4.30 p.m., M.R.C.P. Course in Chest Diseases.

Manchester Royal Infirmary.—*Tues.*, 3.30 p.m., Professor G. Jefferson, Head and Spinal Injuries; Mr. E. Matthews, Jaw Injuries. *Fri.*, 3.30 p.m., Professor J. Morley, Abdominal Injuries; Mr. A. Graham Bryce, Chest Injuries.

DIARY OF SOCIETIES AND LECTURES

Royal Society of Medicine

Section of Therapeutics and Pharmacology.—Tues., 2.30 p.m. Papers by Dr. C. A. Green: Preliminary Observations on the Use of Convalescent Serum in the Treatment of Acute Rheumatic Fever. Dr. I. H. Maclean: Prophylactic Vaccination against Whooping-cough.

Section of Comparative Medicine.—Wed., 2.15 p.m. Discussion: Nervous Affections in Man and Animals. Openers: Dr. G. M. Findlay, Dr. J. R. M. Innes, Dr. Dorothy Russell. Members of the Section of Pathology are specially invited to attend the meeting.

Chadwick Trust.—At Royal Society of Tropical Medicine and Hygiene, 26, Portland Place, W., *Tues.*, 2.30 p.m. Sir William Savage, M.D.: The Health Aspects of Canned Foods.

Medical Society of Individual Psychology, 11, Chandos Street, W.—*Thurs.*, 2.30 p.m. Paper by Dr. H. Crichton-Miller: National Emergency; Discipline and Leadership.

Medical Society of London, 11, Chandos Street, W.—*Mon.*, 4.30 p.m. Discussion: Induced Pyrexia. To be introduced by Dr. F. J. Nattrass and Dr. George Graham.

Royal Institution, 21, Albemarle Street, W.—*Tues.*, 2.30 p.m., Sir Frederick Keeble, F.R.S., Food Production in War Time.

South-West London Medical Society.—At Bolingbroke Hospital, Wandsworth Common, S.W., *Wed.*, 3 p.m. Dr. Allen Piggot: Demonstration and History of Pathological Specimens.

B.M.A.: Branch and Division Meetings to be Held

South Wales and Monmouthshire Branch: Swansea Division.—It has been proposed to hold a supper at the Hotel Metropole, Swansea, provided a sufficient number of members are prepared to attend.

Surrey Branch: Guildford Division.—At Royal Surrey County Hospital, Guildford, Thursday, December 14, 2.30 p.m. Dr. Dennis Embleton: "Cerebrospinal Fever."

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this heading is 9s. This amount should be forwarded with the notice, authenticated by the name and address of the sender, and should reach the Advertisement Manager not later than the first post Tuesday morning to ensure insertion in the current issue.

DEATH

Whiteside.—On November 18, 1939, William Cecil Whiteside, M.B., Ch.B.Ed. Aged 69.

EXTENSION OF HEALTH INSURANCE

Dependants of Men on Active Service

The following letter has been sent by the British Medical Association to the Ministry of Health:

> Dear Sir,
>
> In recent weeks the Association has been giving careful consideration to the question of the medical attendance and treatment of the dependants of men who are serving in the ranks of His Majesty's Forces.
>
> It is realized that the pay and allowances of such men are in the majority of cases insufficient to enable them to provide the necessary medical attendance for their dependants. Such a state of affairs would leave for many the Public Assistance machinery as the only available channel through which they can obtain the attendance they need. It is considered to be wholly undesirable that the dependants of men who are serving their country at this time of national emergency should need to have recourse to the Poor Law as the agency for securing facilities which are essential to their well-being.
>
> It is within the knowledge of the Ministry that the Association's general policy is that the facilities now available to insured persons under the National Health Insurance Acts should be made available also to the dependants of such insured persons. While such an extension would, of course, be welcomed at the appropriate time, it is desired now to urge that the Government should accept responsibility for a limited extension by providing medical care, similar to that now available to insured persons, for the dependants of all men in the Armed Forces whose total income is below £250 per annum. The Association would be grateful if the Government would give immediate consideration to this question and inform the Association of its views.
>
> Yours faithfully,
>
> G. C. Anderson,
> *Secretary.*

A REMINDER TO SERVICE MEMBERS OF THE B.M.A.

Reduced Rate of Subscription

Members of the Association who are serving with His Majesty's Forces are reminded that under By-law 15 they are entitled to enjoy a reduced subscription rate of £2 2s. per annum. In connexion with the subscription which is due on January 1, 1940, the applications for which are now being prepared, steps have been taken to reduce the claim to £2 2s. in the case of those members of the Association known by the Central Office to be serving with the Forces. While every effort is being made to ensure accuracy, it is possible that in some cases a claim will be made for the ordinary home standard rate. If this should prove the case members entitled to claim the Service rate are asked to return the form, when an amended application will be sent.

Delivery of the "British Medical Journal"

The Central Office is anxious to ensure that the weekly issue of the *British Medical Journal* reaches all members of the Association, particularly those in the Services. In the majority of cases the office has been notified of any changes of address which have followed the calling up of men. Members who have not already done so, and who wish the *Journal* forwarded to them at their Service unit, are asked to furnish the Central Office with their address in order that the change may be made with the least possible delay.

The General Purposes Committee of the Society of Medical Officers of Health, which, in view of the difficulty of calling the Society's council together at the present time, has been given wide powers, decided at a recent meeting to seek a deputation with the Ministry of Health and the Ministry of Home Security on certain defects in the administration of the medical and public health aspects of civil defence and casualty treatment services. The deputation, which will include Dr. Cyril Banks, Professor R. M. F. Picken, and Drs. James Ferguson, Gordon Lilico, and T. N. V. Potts, will also urge consultation between the Departments and the Society's representatives whenever new points of policy on these matters are under consideration.

At the same meeting the committee decided to ask the Ministry of Health to postpone the new scheme for the supply of milk at a reduced price to nursing and expectant mothers and children under 5. It was felt that the proposals might have a detrimental effect on maternity and child welfare work in so far as provision of milk under the present schemes was definitely related to attendance at welfare centres; further, many medical officers of health believed that dried milk had scientific advantages over liquid milk in these schemes. It was also considered that the additional administrative burden at a time when public health departments were fully occupied would be a serious matter.

Correspondence

Terms of Service and Air Raid Casualties

SIR,—In the *Supplement* of November 4 (p. 215) there appeared under "War Notices" in a paragraph on the general practitioner and air raid casualties the sentence: "In so far as the injured persons are entitled to medical benefit under national health insurance they are already provided for."

On February 15 of this year a conference of all Local Emergency Committees took place in the Great Hall of B.M.A. House, and several hundred representatives from all over the country attended to hear the Minister of Health, Dr. Elliot, give an address on the medical services in war time. After his address a number of questions were submitted in writing to the Minister, of which one (by the undersigned) asked whether medical attendance on war casualties would form part of the terms of service under the N.H.I. Acts. The Minister's reply (of which there must be shorthand records in the hands of the Secretariat) was an unequivocal assurance to the contrary, which was greeted with some cheerful applause.

While most doctors are quite ready to do any kind of war work they are not prepared to have so great a risk thrust upon them without some additional consideration for their services. The ever-rising cost of living, petrol, drugs and dressings, the high taxation, decreasing panels, and moribund private practices are all factors calling for compensation somewhere, if we are to continue paying our bills and subscriptions. There is a growing feeling among the profession that a small share of the £6,000,000 which this country is spending a day on war alone might be reserved for providing the nation with *rational* and *adequate* services such as ours.—I am, etc.,

London, W.10, Nov. 28. GEORGE DE SWIET.

⁂ The text of a letter from the British Medical Association to the Ministry of Health urging that treatment of air raid injuries should be outside the scope of medical benefit under national health insurance was published in the *Supplement* of December 9, page 237.—ED., *B.M.J.*

Medical Staffing of First-aid Posts

SIR,—On December 1, 1939, a meeting was held of practitioners who had undertaken service at first-aid posts in the area of the Wandsworth Division of the B.M.A. Out of a total of forty, twenty-seven attended.

The latest proposal of the Ministry of Health for the medical staffing of aid posts was discussed, and it was the unanimous opinion of the meeting that practitioners appointed to be in charge of aid posts in the area of the Wandsworth Division should decline service unless a deputy was properly appointed to each post and suitably remunerated. It was felt that for a sum of £75 per annum, entailing in addition to other duties three visits of inspection and instruction a week, the medical officer in charge of the post could not reasonably be expected to remain on call for twenty-four hours a day, and that for no retaining fee at all a deputy could not be expected to hold himself in readiness during such times as the practitioner in charge was not available. It would appear more than probable that the ultimate result would be that the services of any practitioner available would have to be requisitioned in the event of the practitioner in charge not being available. This, it was felt, was contrary to the public interest, inasmuch as it would appear highly desirable, under the conditions likely to prevail after an air raid and bearing in mind that the lay personnel in many cases have as yet to see a badly cut finger, that a practitioner familiar with the precise location of the post, the personnel, the distribution of instruments, drugs, and dressings, and the type of appliance available, as well as the general lay-out of the post, would be a *sine qua non* of efficient service.

The views of other practitioners interested in first-aid work would be welcomed.—I am, etc.,

R. A. MITCHELL, M.B.,
Dec. 4. Honorary Secretary and Emergency Officer, Wandsworth.

Capitation Fee in War Time

SIR,—I wonder what other general practitioners are thinking about the new financial problems presenting themselves in these troubled times. To meet the increased cost of living we find that wages, allowances, unemployment assistance, etc., are being increased. The farmer is going to be permitted to sell milk at one penny per quart more after January 1, 1940, because he must meet the increased cost of feeding-stuffs. Is the panel practitioner given an increased mileage allowance under the national health insurance to meet the increased cost of petrol? Is the practitioners' capitation fee increased to meet the loss in income arising in circumstances consequent on present conditions? Is it fair or honest to increase our fees to private patients to pay for the increased cost of travelling to insured patients?

What are the answers to these questions? If the time is ripe for increased wages, prices, etc., is it premature to ask for some consideration of the above-mentioned matters?—I am, etc.,

Callander, Dec. 2. F. C. M. MCILWRICK, M.B., Ch.B.Ed.

⁂ The text of a letter which the Insurance Acts Committee of the B.M.A. has sent to the Ministry of Health on the capitation fee was published in the *Supplement* of December 2, p. 231.—ED., *B.M.J.*

SIR,—In the *Supplement* of December 2 (p. 231) you quite rightly call attention to the capitation fee question. Admittedly this fee is totally inadequate and should be in the region of 15s. per annum for the service now given under the National Health Insurance Acts, but there is one still more serious factor at work to-day that you pay no attention to at all. When the Military Training (Militia) Act was passed in April we were told that those men called up would remain upon our panel and would not be struck out. Since September, however, our losses have been serious, and each month we are asked by the Panel Committee to send in the records of young men who have "joined the Forces." Our panels are steadily declining, costs are rising quickly, taxation is already savage, and we are signing on very few new panel patients, so we cannot maintain our figures.—I am, etc.,

Lincoln, Dec. 3. C. A. H. FRANKLYN.

Fees for Emergency Treatment and Anaesthetics

SIR,—A notice has been circulated in the area that, acting on the suggestion of the Minister of Health, the insurance committee, in conjunction with the panel committee, has decided that for the period of the war emergency claims for fees for the administration of anaesthetics and for emergency treatment shall be suspended [*sic*]. I shall be pleased to know if the two committees have the power thus to set aside one of the provisions of the Act. And I shall be pleased also to learn just how this decision is going to help to win the war or in any way affect its course.—I am, etc.,

Ludlow, Nov. 24. T. HUNTER.

⁂ The Secretary of the British Medical Association makes the following comment: The proposal that claims for emergency treatment and anaesthetists' fees should be discontinued for the duration of the war was one of a number of suggestions for reducing the administrative work normally done by panel and insurance committees. These special payments are first charges on the Local Practitioners' Fund before its distribution to individual practitioners.

Medical Students and Military Service

SIR,—Your correspondent "Alpha," whose letter appears in the *Supplement* of December 2 (p. 235), suggests that still more medical students should be "reserved." While in the last war there was a great shortage of doctors and students, this time there are already quite enough of both, and I suggest that it would be more in the national interest if, instead of unnecessarily increasing the number of reserved men, more were left for the fighting forces.

I cannot quote figures (comparing the number of doctors and students available now with the number in 1914); but in view of my difficulty in obtaining employment—whether in a hospital or the R.A.M.C.—I conclude that there is already a sufficient number of doctors. There is already a reserve of several thousand students, without adding more. If in the last war there were too few doctors and students, is there not a danger of the pendulum swinging too far in the opposite direction this time? For one thing, how on earth are we all to get jobs when the war is over?—I am, etc.,

Dec. 2. NEWLY QUALIFIED.

EMERGENCY MEDICAL SERVICE OF NORTHERN IRELAND

The Ministry of Home Affairs for Northern Ireland has issued the following memorandum on the conditions of service in the Emergency Medical Service.

1. Appointment to the Emergency Medical Service will be made by the Ministry and will continue for the duration of the war or for such period as the Ministry may determine. Subject to the essential needs of the service and the advice of the Emergency Committee of the British Medical Association the Ministry will be prepared to release members whose services are required by His Majesty's Forces.

2. The duties of members in the treatment of casualties will include treatment of persons transferred from one hospital to another by direction of the Ministry in order to provide for casualties as well as casualties caused directly by hostile attack, and of such other persons or classes of persons as may from time to time be deemed to be casualties; and will include treatment in extern departments of hospitals as may be necessary.

3. The duties of members will be performed in such hospital or hospitals in Northern Ireland as the Ministry may from time to time direct, but duty will, so far as possible, normally be assigned in the hospital to which the member is attached as a member of the staff.

4. Each member will attend for duty at the required hospital at such times as may be specified by the Ministry in any general or specific direction, but except in the event of an actual or impending attack or a special emergency members will be permitted to attend at such times convenient to themselves and to the hospital authority as are consonant with the due performance of their duties.

5. Members may engage in private practice and hold appointments in so far as is consistent with the performance of their duties.

6. The remuneration of members of the Emergency Medical Service will be provided by payment to the accredited representative of the medical staff of each hospital in which casualties are treated of a capitation allowance at the rate of 2s. 6d. per day for each casualty (as defined in paragraph 2 of this memorandum) under treatment in that hospital. The remuneration of individual members serving in each hospital, whether ordinarily attached or temporarily assigned to the staff of that hospital, will be paid by the accredited representative out of the fund provided by the capitation allowance in such proportions as the members so serving shall determine. The accredited representatives will account to the Ministry for all moneys so received and paid by them at such times and in such manner as the Ministry may require.

7. Selected members who are required to proceed in an emergency or for special duty to hospitals to which they are not ordinarily attached or normally assigned for duty will, in lieu of participating in the capitation allowance at the hospital to which they proceed, receive remuneration on a sessional basis according to the following scale:

Specialists.—2½ guineas per session up to a maximum of five sessions in any one week and 2 guineas for each additional session, subject to a general maximum of 120 guineas in any one quarter.

Assistants to Surgical Specialists.—1½ guineas per session up to a maximum of five sessions in any one week and £1 5s. for each additional session, subject to a maximum of 75 guineas in any one quarter.

Anaesthetists.—If required to provide their own apparatus, 2 guineas per session. If not required to provide apparatus, at the same rates as assistants.

(If anaesthetic drugs are not provided by the hospital an allowance for drugs used will also be made.)

For the purpose of this paragraph a session consists of a period of two hours or any part thereof, running from the time of departure for duty and terminating on return to home or normal station provided that the time occupied in travelling is shown to the satisfaction of the Ministry to be reasonable in the circumstances. Payment of sessional fees will be made by the Ministry on the certificate of the hospital officer who has directed the duty.

8. No allowance will be paid in respect of travelling or subsistence in proceeding to assigned posts for duty. Where, however, members are required under paragraph 7 of this memorandum to proceed on special duty more than five miles from their normal station the member in whose car they travel will receive an allowance at the rate of 3d. per mile, unless petrol is provided at public expense; a party not exceeding four in number will be expected to travel in one car. Arrangements will be made for journeys on special duty.

9. Members of the Emergency Medical Service will be entitled to the benefits of any arrangements which may be made in respect of the death or injury on duty of members of Civil Defence Services. Membership will not, however, confer any other right to pension, gratuity, or compensation on termination of services.

10. Directions and instructions of the Ministry will be communicated to members by the officers authorized by law (the Minister, Parliamentary Secretary, Permanent Secretary, or an Assistant Secretary), or by the Chief Medical Officer or the hospital officer of the Ministry. No directions or instructions, unless issued by an authorized officer, should be accepted by members nor will be recognized by the Ministry.

Naval, Military, and Air Force Appointments

ROYAL NAVAL MEDICAL SERVICE

Surgeon Commander H. E. Scargill has been placed on the Retired List with the rank of Surgeon Captain.

Surgeon Lieutenant R. M. Kirkwood has been transferred to the Emergency List.

Surgeon Lieutenant (Emergency List) T. F. Miles to be Surgeon Lieutenant-Commander (Emergency List).

ROYAL ARMY MEDICAL CORPS

Captain A. N. T. Meneces to be Major.

Lieutenant J. M. Corall to be Captain, with seniority October 22, 1938 and precedence next below Captain B Lapedus; Lieutenant S. O. Bramwell to be Captain, with seniority October 22, 1938, and precedence next below Captain J. M. Corall.

Lieutenants F. B. Bagshaw and H. J. A. Richards to be Captains, with seniorities November 4, 1938, and November 5, 1938, respectively.

Lieutenants J. H. Gibson, H. A. Bowker, H. C. Jeffrey, G. L. Humphreys, J. J. Justice, D. A. Ireland, G. F. Edwards, J. Baxter, H. H. Johnston, A Bennett, P. E. R. B. Unwin, R. G. Davies, D. S. Toole, R. D. Bell, A. Crook, R A. Daly, and E. T. St. M. Brett to be Captains.

The appointments of Lieutenants F. B. Bagshaw and H. J. A. Richards have been antedated to November 4, 1937, and November 5, 1937, respectively, under the provisions of Article 36, Royal Warrant for Pay and Promotion, 1931, but not to carry pay and allowances prior to November 4, 1937, and November 5, 1937, respectively.

ROYAL AIR FORCE MEDICAL SERVICE

Air Commodore W. Tyrrell, D.S.O., M.C., has been granted the acting rank of Air Vice-Marshal.

Air Commodore B. A. Playne, D.S.O. (R.A.F. ret.), has relinquished, at his own request, the rank of Air Commodore whilst re-employed with the Royal Air Force and has been granted the rank of Group Captain.

ROYAL AIR FORCE RESERVE: MEDICAL BRANCH

R. S. Maclatchy has been granted a commission as Flying Officer in Class D, with effect from November 27, 1939, and with seniority November 27, 1933.

AUXILIARY AIR FORCE: MEDICAL BRANCH

Flying Officers N. R. Smith B. Rothery, and G. A. H. Norman to be Flight Lieutenants.

ROYAL AIR FORCE VOLUNTEER RESERVE: MEDICAL BRANCH

D. D. MacDonald has been granted a commission as Flying Officer. (Substituted for the notification in the *London Gazette* of October 20.)

The following have been granted commissions as Flying Officers for the duration of hostilities: J. S. Astbury, J. Apley, J. R. Connelly, P. C. Conran, T. A. James, M. J. Lowther, W. H. Mirkin, K. D. F. Morle, M. Stein, M. Pearson, J. S. Davies, and J. L. Trainer, L.R.C.P. and S., L R.F.P.S., L.D.S.

REGULAR ARMY RESERVE OF OFFICERS

ROYAL ARMY MEDICAL CORPS

Majors C. de W. Gibb and A. Mearns have ceased to belong to the Reserve of Officers on account of ill-health.

Captain T. S. Cave, from Regular Army Reserve of Officers, Royal Artillery, to be Captain, with seniority November 13, 1936. (Substituted for the notification in the *London Gazette* of September 8.)

Captain F. P. Freeman, M.C., has ceased to belong to the Reserve of Officers on account of ill-health.

L. W. H. Bertie, late Second Lieutenant, Special List, to be Lieutenant. (Substituted for the notification in the *London Gazette* of September 15.)

SUPPLEMENTARY RESERVE OF OFFICERS: ROYAL ARMY MEDICAL CORPS

The notification in the *London Gazette* of September 12 regarding Lieutenant A. M. Critchley has been cancelled.

The notifications in the *London Gazette* of October 6 regarding Lieutenants A. C. Stevenson and D. A. Lowe have been cancelled.

TERRITORIAL ARMY

Colonel L. B. Cane, T.D., A.D.M.S., 54th (E.A.) Division, has retired on completion of tenure.

Royal Army Medical Corps

Lieutenant-Colonel A. J Gibson, T D., has relinquished his commission on account of ill-health.

Major I. H. Lloyd-Williams, from R.A.M.C., temporary commission, to be Major.

Major A. Barr has relinquished his commission on account of ill-health.

Captain F. W. Bury, from Territorial Army Reserve of Officers, R.A.M C., to be Captain.

Captain R. J. Watson, M.C., from Territorial Army Reserve of Officers, General List, Royal Artillery, to be Captain, with seniority September 15, 1935.

Captain G. S. Adams from Territorial Army General List, O.T.C., to be Captain with seniority December 28, 1937.

Captain D. Macleod has relinquished his commission on account of ill-health.

Lieutenant J. C. Caird, from Territorial Army Reserve of Officers, Scouts, to be Captain, with seniority February 2, 1937.

Lieutenant J. K. Sutherland to be Captain, with seniority May 29 1938.

Lieutenant P. J. B. Dyce has resigned his commission.

Lieutenants J. Black and W. L. Fulthorpe have relinquished their commissions on account of ill-health.

Lieutenant W. I. Walker to be Captain.

Lieutenant R. I. Mitchell from Territorial Army General List, Infantry Unit, O.T C., to be Lieutenant.

Lieutenant L. R. Flowers, from Territorial Army Royal Berkshire Regiment, to be Lieutenant.

Lieutenant D. J. Macrae, from Seaforth Highlanders, to be Lieutenant.

Second Lieutenant F. S. Fiddes, from Territorial Army Reserve of Officers, General List, Infantry, to be Lieutenant.

To be Lieutenants: J. C. Hill, C. D. Weir, J. A. Reid, W. G. H. Allen, J. E E. Hughes, T. A MacGibbon, and T. L. Oliver.

LAND FORCES: EMERGENCY COMMISSIONS

Royal Army Medical Corps

The following to be Lieutenants and have been promoted to the rank of Acting Colonel: Lieutenant-Colonel C. M. Page, D.S.O., R.A.M.C., Militia (retired) and has relinquished the rank of Lieutenant-Colonel; Major A. W. Stott, R.A.M.C., T.A (retired), and has relinquished the rank of Major; Captains J R. Rees, R.A.M.C. (retired), and H. Yellowlees, O.B.E., R A M.C. (retired), and have relinquished the rank of Captain; Sir C G. Gordon-Watson, K.B E., C.M.G., H. L. Tidy, F. A. Juler, and J. T. Ingram

The surname of C. E. Hurley is as now described and not as notified in the *London Gazette* of November 15.

Lieutenants H. S. Calder and A. P. Procter have relinquished their commissions on account of ill-health.

To be Lieutenants: A. W McKenny-Hughes, F J C. Johnstone, D. Mackenzie, J. R. Macintyre, G. C. Cooper, H. B Hodson, J. M. Houston, W. Belton, W D. R. Thompson, R. J. Tolcman, T. P. Sewell, G. F. Anderson, J. A. A. Duncan L. D. Dennard, J. C. B. Bone, J. B. C Madge, W. S. Braidwood, G. McL. Gorrie, A. Lutton, G. M. Heap, G. Woodruff, C. H. Comrie, E. E. Satchwell, A. G. Williams, A. C. Barker, C. E. M. de Gruchy, F. Duval, W. Falconer, L. M. Rubein, G. H. Darke, L. Griffiths, O. F. Barr, E. Gillett, F L. Lydon, D. G. Adamson, L. D. M. Gavin, J. A. Gordon, R. Semple, S. W. H. Stuart, H. R G. Davies, C J. D. May, C. N. Mills, J. L. Reynolds, F. J. C. Smith J. L. Treneman, P. K. Walker, F. Ayrey, W. O. Macfeat, D. W. Rossiter, R. W. Gunderson, T E. Henderson, L. V. Macdonald, D. J. A. MacLean, R. H. M. Ross, R H. D. Short, J. E. L. Bendor-Samuel, H. Rosenberg, J. R. Sweeting, A. Taylor-Smith, G. W. Almeyda, J. B. Dowe, M Gaba, A. O. Karstaedt, C. J. Evans, A. M. Baillie, M. A. Chamberlain, A Findlay, G. A. D. Gordon, H. W. Gray, G. Ralston, G. Rosemont, L. S. Woolf A. L. Dick, A. W. C. Mellor, E. A. Robertson, T. J. Steven, A. J. Warren, F. J. Biddle, F. J. McDermott, R. Macnair, R. H. Mumford, L. Saunders, D. R. Buller, M. W. Paterson, E. S. Ashforth, T. A Clarke, B. W. Macdonald, G. H. Evans, G. N. McLaren, W. Gavin, H. Graham, A. P. R. Borrowman, T. J. Clune, W. L. Young, N. F. Seed, W. Murphy, A. Reid, T. Duncan, I. Lloyd, W. G. P. Mair, I. Murray, F. H. Morrell, G. L. Ritchie, R. F. White, R C S. Dick, A W. Green, W. M. K. McLellan, A. McDiarmid, E. Doherty, F. N. Woods, J. W. McLaren, H. E. Brown, N B. Walker, A. Henderson, E. I. Harper, W. Henderson, J. Thomson, R. D. Mackenzie, J. D. McLennan, J. C. G. Whitelaw, G. E Calvert, W. N. Murray, A. V. Stevens, J. W. Doupe, J A Robertson, A. J. Martin, J. F. Venables, and H. H Clay.

To be Medical Officers with the relative rank of Lieutenant: Muriel Boycott and Ethel Whitby

INDIAN MEDICAL SERVICE

The Secretary of State for India has appointed to the Civil Branch of the Indian Medical Service the following officers of the Indian Medical Service with effect from the dates indicated in parentheses: *Government of India:* Major S. S. Bhatnagar (June 26, 1938); Major Jaswant Singh (July 11, 1938); Major M. K Kelavkar, M.B.E. (October 20, 1938); Major W. F. Cooper (November 9, 1938). *Bombay:* Captain L. Feinhols (August 5, 1938). *Bengal:* Captain J. W. D. Goodall (September 18, 1938); Major E. A R. Ardeshir (November 26, 1938). *Punjab:* Captain F. V. Stonham (September 27, 1938). *Bihar:* Captain W. B. Stiver, L.M.S. (August 28, 1938); Captain F. W. Whiteman (September 8, 1938). *Central Provinces:* Captain M. Sendak (July 29, 1938); Captain F. C. Leach (December 6, 1938). *Orissa:* Captain J. W. Bowden (October 11, 1938).

The Secretary of State for India has sanctioned the reversion to military employment of the following officers of the Indian Medical Service (Civil) with effect from the dates indicated in parentheses: *Government of India:* Major W. F. Cooper (December 30, 1938). *Central Government:* Lieutenant-Colonel R. L. Vance (November 12, 1937); Lieutenant-Colonel W M. Will (October 31 1938); Captain C. J. H. Brink (November 27, 1938); Colonel E. G. Kennedy (April 20, 1939). *Madras:* Major J. S. McMillan (September 1, 1937); Lieutenant-Colonel C S. V. Ramanan (November 6, 1937). *Bombay:* Captain P. I. Franks (October 29, 1937); Captain W. W. Laughland (June 4, 1938). *Bengal:* Lieutenant-Colonel R. E. Flowerdew, C.I.E. (May 25, 1937); Major B. N. Hajra (February 14, 1938); Major A. K. Gupta (February 14, 1938). *United Provinces:* Lieutenant-Colonel B R. Chaudhri (April 17, 1939); Captain Jaswant Singh (September 10, 1937); Major R. D. Alexander (August 3, 1938). *Bihar:* Captain W. B Stiver (November 12, 1938); Captain F. W. Whiteman (December 5, 1938); Major G. P. F. Bowers (October 4, 1937); Lieutenant-Colonel H. M. Strickland (November 10, 1937). *Central Provinces and Berar:* Lieutenant-Colonel R. A. Logan (November 20, 1937); Lieutenant-Colonel J. Carrey (March 4, 1938); Lieutenant-Colonel J. E. Ainsley (August 2, 1938); Major V E. M Lee (August 19, 1938).

Major-General E. W. C. Bradfield, C.I.E., O.B.E., K.H.S., Director-General, Indian Medical Service, has been granted leave on average pay for one month and one day and in continuation leave on half average pay for four months and six days with effect from September 29.

Colonel G. G. Jolly, C.I.E., V.H.S. Inspector-General of Civil Hospitals, Punjab, has been appointed to officiate as Director-General, Indian Medical Service, with effect from September 29

Colonel G. G. Jolly C.I.E., V.H.S., has been granted the local rank of Major-General, without effect on pay and pension, whilst officiating as Director-General, Indian Medical Service

Colonel Sir A. J. H Russell, C.B.E., has retired from the Service.

The retirements of Colonel J A S. Phillips, C.I.E., Lieutenant-Colonel F. A. Barker, C.I.E, O.B.E, and Lieutenant-Colonel S. A. Phatak, have been permitted subject to His Majesty's approval.

Major H W. Farrell an officiating Agency Surgeon, has been employed as Chief Medical Officer and Inspector-General of Prisons in Baluchistan, with effect from October 4, 1939

Major E. A. O'Connor, an officiating Agency Surgeon, has been appointed as Civil Surgeon, Quetta-Sibi with effect from October 5, 1939.

Major F. H. Whyte has been appointed to the post of Civil Surgeon, New Delhi, with effect from October 9, 1939

Major K H. A. Gross, M C., an officiating Agency Surgeon, on return from leave has been appointed as Agency Surgeon in Bundhelkand with effect from September 30, 1939.

Majors R. W. H. Miller and P. A. C. Davenport to be Lieutenant-Colonels.

Captains F. M. Khan and D Datt to be Majors.

Captain M. G Saincer to be Major (provisional).

Diary of B.M.A. Central Meetings

December

20 Wed. Executive Committee, 2 p.m.
29 Fri. Journal Board, 11.45 a.m.

B.M.A.: Meetings of Branches and Divisions

Edinburgh and South-East of Scotland Branch: City of Edinburgh Division.—Members of the Division are informed that Professor Stanley Davidson and his staff will hold a clinic in Ward 27 in the Royal Infirmary, Edinburgh, every Tuesday from 2 to 4 p.m., for patients suffering from the chronic rheumatic diseases.

Hertfordshire Branch: St. Albans Division.—At Wellington Court, Bricket Road, St. Albans, Friday, December 15, 8.30 p.m. Dr. E. R. Cullinan: "Recent Drugs and their Uses."

Postgraduate News

The Fellowship of Medicine announces the following courses of instruction for Final F.R.C.S. candidates: (1) surgical tutorial classes, twice weekly, 4.30 p.m., continuing until January 25, 1940, at the Medical Society of London, 11, Chandos Street, W., the lectures for this week being on the sympathetic nervous system by Mr. G. C. Knight on December 19, and on testicle and prostate by Mr. Kenneth Heritage on December 20; (2) a comprehensive course at the Royal Cancer Hospital daily from 9.30 a.m. until 1 p.m., continuing until January 27, 1940; (3) short courses in pathology will be given in January, each course consisting of two demonstrations (in the same week) from 2 p.m. to 3.30 p.m., and each course limited to six postgraduates; (4) an evening course at St. Mary's Hospital on Tuesdays, Wednesdays, and Thursdays, at 8 p.m., from December 19, 1939, to January 25, 1940 (excluding Christmas week), and consisting of tutorial classes on Tuesdays and Thursdays and a clinical class on Wednesdays.

WEEKLY POSTGRADUATE DIARY

Fellowship of Medicine and Postgraduate Medical Association, 1, Wimpole Street, W.—*St. Mary's Hospital*, W.—Tues Wed., and Thurs., 8 p.m., Final F.R.C.S., Clinical and Tutorial Course. *Royal Cancer Hospital*, Fulham Road, S.W.—Daily 9.30 a.m. to 1 p.m., Comprehensive Final F.R C.S. Course. *Brompton Hospital*, S.W.—Mon. and Wed., 4.30 p.m., M.R.C.P. Course in Chest Diseases. *Medical Society of London*, 11, Chandos Street, W.—Surgical Tutorial Classes Tues., 4.30 p.m., Mr. G. C. Knight, Sympathetic Nervous System; Wed., 4.30 p.m., Mr. Kenneth Heritage, Testicle and Prostate.

Manchester Royal Infirmary.—*Tues.*, 3.30 p.m., Dr. F. R. Ferguson, "Air Raid" Neuroses and their Treatment. *Fri.*, 3.30 p.m., Drs. J. Wharton and P. B. Mumford, Poisoning by "Mustard Gas" and Other Poison Gases, with Special Reference to the Treatment of Lesions of the Eyes and Skin

VACANCIES

Examining Factory Surgeons.—The following vacant appointments are announced: Wollaston (Northamptonshire); Yarmouth (Isle of Wight); Balfron (Stirlingshire). Applications to the Chief Inspector of Factories, Home Office, Whitehall, S.W.1, by December 28.

APPOINTMENTS

Burden Neurological Institute, Stapleton, Bristol.—Honorary Surgeons: Wylie McKissock, M.S, F.R.C.S., and F. Wilfred Willway, M.S., F.R.C.S.

Lewis, J. T. R., M.D., D.P.H., Deputy Medical Officer of Health and Deputy School Medical Officer of the County Borough of Croydon.

Payne, D. D., M.D., D.P.H., Medical Officer of Health and School Medical Officer of the Borough of Harrogate.

Examining Factory Surgeons.—Edward Johnson, M.B., Ch.B., for the Cranborne District (Dorsetshire); J. E. R. Palmer, L.M.S.S.A., for the Megavissey District (Cornwall); H Stewart, M.B., Ch.B., for the Littlehampton District (Sussex).

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this heading is 9s. This amount should be forwarded with the notice, authenticated by the name and address of the sender, and should reach the Advertisement Manager not later than the first post Tuesday morning to ensure insertion in the current issue

MARRIAGE

Cook—Reid.—On December 8, James Cook, F.R.C.S.Ed., to Carolyn Winona, daughter of Colonel and Mrs. H. G Reid.

DEATH

Coleman.—On December 10, 1939, at Sandford, Llandudno, Olive May, the dearly loved wife of A. H. Coleman, F.R.C.S., in her 53rd year. Interred Tuesday, December 12

IMPLICATIONS OF HEALTH INSURANCE IN AMERICA*

BY

J. A. HANNAH, M.D.

Managing Director, Associated Medical Services Incorporated, Toronto

During the past two years my full time has been devoted to the subject of health insurance, in an endeavour to do something practical to bring the profession in Ontario to an awareness of its duty and responsibility toward this social problem which has become as important as our scientific advances. Let us make no mistake; only in so far as we as a profession know the problem of health insurance and are willing to cope with it will there be any form of satisfactory answer. It is suicide for us to allow laymen, politicians or otherwise, to gain control of this situation. This we have found through our experience in hospital work. Hospitals are no longer the servants of physicians, as originally intended: the servant has become the master, to the detriment of both profession and public. This problem has never been satisfactorily answered, nor will it ever be until the profession has assumed its full responsibility, not only in regard to practice but also in relation to its economic adjustment.

I should like to take you with me through a very tangled maze of developments in Ontario which have led to my presence here to-day. In so doing it may be that we can learn something of the responsibility of the profession in relation to this tremendous problem of health insurance in America.

Demand for Health Insurance in America

As early as 1882 European countries felt the urge for socialized medicine, and since that time some thirty countries have adopted insurance in one form or another. There are several reasons why we in Canada and the United States have not found it necessary or convenient to socialize the practice of medicine: (1) Our populations have for the most part been scattered over large areas; this sparsity has rendered it difficult to systematize our economic methods and for the public to become aware of the needs of their fellow men. (2) At the same time our standard of living at its worst has been higher than that of the masses in Europe. (3) This last, combined with the existence of a virile, rugged individualism, has delayed the demand for social medicine until the recent depression, which, like our winter, seems so loath to leave us.

Factors other than the "depression" have also, however, been at work bringing about a demand for a change in our medical economy.

1. Every advance in scientific knowledge brings with it its increased cost in application to the patient. Insulin, despite all its benefits, adds to the accumulating cost of medicine. The rapidity with which expensive *x*-ray equipment becomes obsolete increases costs. However beneficial, these new therapeutic methods do add to the cost, and to the ever-increasing difficulty of meeting it from income, taxation, or philanthropy. The only apparent diminishing entity has been the income of the physician, who has assumed a larger and larger proportion of the cost of medical care without remuneration.

2. Another factor contributing to public demand has been the change in our general economic standards and methods. It used to be accepted as good practice to save your pennies to buy the necessities. Now it seems to be accepted practice to buy the luxuries and pay as you can (or perchance, if, as, and when they catch you). It works. There is one car for every five people in Ontario, despite the fact that 94 per cent. of earners have incomes of less than $3,000. These same people have also their over-stuffed furniture, their radios, and other luxuries.

3. In contrast with this economic revolution in regard to the purchase of necessities and luxuries, medical economy has gone on its own way, believing that nothing could or should be done about it, with the result that medical care has been neglected, while the profession finds an ever-increasing hostility towards the so-called "high cost of medical care." It is an interesting commentary on our methods that no one complains about the high cost of tobacco, cosmetics, or motion pictures; yet there is as much or more money spent on these things as on medical services. Why? Because, if a package of cigarettes is finished, another may be bought for a quarter or a dime. If neither is available our friend will share his, and consumption continues to the profit of the tobacco combine. Not so the cost of medicine! While our client remains well he may contribute nothing to the maintenance of physician, hospital, nurse, or equipment. When he does fall ill he must pay not only for his illness but also for his preceding period of health. The members of the profession and the equipment must be available in health as well as illness. To add to the general confusion, illness impairs earning capacity, and no one, not even the physician, can guess when the illness will occur or what the magnitude of the bill will be.

Under such conditions it is little wonder that there has been a persistent and steadily increasing demand for some method of budgeting against the cost of medical care, both from the public and the profession. Let us make no mistake: if we who know something of the intricacies and intimacies of practice do not meet the situation, then others who are less well informed but as well intentioned will, and all will be subject to a period of dissatisfaction and confusion, and progress will be impeded scientifically as well as economically.

Imminence of Socialized Medicine

1. Until recently it was not unusual for certain sections of the profession to insinuate that such arguments were a figment of the imagination, and if the proponents belonged to the profession a more sinister meaning was attached. The facts have become too apparent and concrete to be denied any longer. In Canada, British Columbia has an Act on her statute books to implement health insurance. The recent Minister of Health of Alberta

---

* Delivered before the Welfare Committee of the Medical Society of New Jersey, April 16, 1939.

has indicated many times that had his Government been returned health insurance would have been an accomplishment. Saskatchewan has had a form of municipal practice for some years. Ontario has had legislation on at least one occasion to bring down, but for some reason has not done so.

2. Recent events in the U.S.A. are too fresh and obvious to require comment from me. I will make only one comment on your country's projected plan: the present estimated contribution from all sources will prove but a mere pittance of what the projected plan will eventually have cost. In both the U.S.A. and Canada there has been an ever-increasing number of voluntary plans coming into effect, particularly for hospitalization. Here again, unless carefully guarded, lies a menace to the profession. At the last annual meeting of the American Hospital Association, held in Dallas, Texas, the New York Hospital plan succeeded in getting a resolution through the convention giving the plan the right to provide its ward subscribers with medical service. Once again the profession is on the verge of surrendering more of its birthright and becoming even more the handmaid of institutions originally designed to be our helpmate.

3. Add to the foregoing the evils of lodge practice, some forms of industrial medicine, and mercenary forms of group practice, and there appears to be a formidable array of encroaching forces making for the destruction of medical practice as it has been known and handed down through the years. If each in turn is carefully analysed it will be seen that it is based on purely economic factors, with little or no regard for that intangible something that raised medicine above the ranks of a trade or a profession and combines both into an art, the tools of which are human understanding, the laws of which know only the needs of human ailment. It knows no race, creed, nationality, or social strata. Such is the heritage which we must protect.

How shall we meet this challenge? Surely not by any attitude of *laisser faire,* hush-hush, or sterile criticism. It must be met in the same manner as we have met our manifold research problems in our scientific field. Some of us must brave the taunts of our so-called economic experts to the point of venturing into research on the subject. Who better to do this than the profession? In my short experience it has become apparent that no one knows what the problem involves. Statisticians, actuaries, and insurance brokers grope hopelessly in their lack of understanding of the problems of medical practice. There is research here to challenge the best brains within our ranks. From among ourselves we must develop researchers who can produce results such that confidence will be inspired in our professional brethren for these medico-economists. We have specialized almost *ad nauseam* in other branches of medicine, but each feels competent to deal with his own and the public's economy in relation to medicine.

Nor will it do for us to regard this particular " specialty " as something beneath professional dignity. No man, however astute, brilliant, or assiduous, can ever comprehend the magnitude and intricacies of this problem unless he first be trained in the profession and have actual experience of its practice. I, personally, cannot deprecate sufficiently this ever-growing tendency of placing non-medical men in executive positions in our hospitals and medical societies. These are positions which should and must be filled from among our own ranks. Until it is done we can expect a continuance and extension of non-medical control over the profession, to the ever-deepening detriment of medical practice and patients alike. In short, the profession must recognize the full implications of responsibility and give leadership. Our problem permits of no alternative.

History of Insurance in Europe

It would be foolish to disregard all the years of accumulated experience of the European countries, as well as of sickness and accident insurance companies. There is something to be drawn even from lodge and industrial practice. Every research problem has its negative and positive values. Those of you who have done research will appreciate the value of the 90 per cent. negative results in any such problem. It is not sufficient to regard any negative result as being detrimental to the progress of the problem in hand. Because we may not like the National Health Insurance Act of Great Britain or State medicine as in Russia it does not mean that they have nothing to offer for our guidance. Because the Danish system may appeal to us it does not mean that we can transplant it to America and expect all its benefits to become immediately apparent. Every process is a growth, and every growth changes in direct proportion to its age, until such time as rigor mortis sets in. The best anyone can do is to eliminate, so far as possible, those factors which appear to give rise to decadence.

So it was that those of us in Ontario, when we started to think about this problem, began our researches by a study of every form of health insurance we could find. The three most fruitful sources were: (1) the National Health Insurance Act of Great Britain; (2) various other voluntary and industrial plans for both hospitalization and medical care on both sides of the Atlantic (in addition, the study by the Committee on the Cost of Medical Care from the American Medical Association also proved useful); and (3) somewhat later, after we had begun activities, we discovered that the Danish plan had much to offer to a democratic system.

This is neither the time nor the place to go into detailed discussion in regard to any of these systems or studies, but some broad principles may be stated. First, and most important, no plan ever came into existence in a finished and satisfactory form; all were found cumbersome and unsatisfactory in their initial stages. The National Health Insurance Act of Great Britain was instituted in 1912, and was a source of some difficulty and worry in its early stages. The Danish system was instituted in 1892 as a voluntary plan under the control of the profession. In twenty years 70 per cent. of the population came under the system, at which time the Government began to use coercion on the remaining 30 per cent. Both systems continue to grow and improve. The most important principle to grasp is that, although the British plan was Governmental and the Danish voluntary, each has been and continues to be a process of growth, each passing through an early stage of irritation requiring adjustment.

The second principle which becomes apparent is that no plan offers any degree of satisfaction until the profession establishes within itself such discipline as will permit of free choice of physician. It must, however, be noted that choice of physician presupposes a very real disciplinary control by organized medicine over its individual members. Liberty of choice cannot be permitted the public if a small percentage of the profession is permitted " licence " in charges and services rendered. The same discipline will be established in regard to the public when the profession has established the ability to control abuses. I shall endeavour later to illustrate how we have set up this control in Ontario.

The third great principle is that no plan ever becomes really successful until the profession recognizes its responsibility and assumes leadership. An attitude of critical indifference intensifies a sense of injustice among both the profession and the public, and leads to ever-increasing coercion by Governments over the profession. An attitude of helpful understanding leads to mutual co-operation. Nothing can, however, be attained by subservience on the part of the profession. Just as the patient awaits instructions from the physician of his confidence, so the public await the leadership of the profession.

A fourth and equally important fact becomes apparent from Government-controlled plans. Every such plan has started from a purely economic point of view. Lloyd George won his mandate from the British public in 1911 on the political battle-cry of " Ninepence for fourpence." In British Columbia the Government first set the economic mould of a little better than $5 per annum for an almost complete medical service. Such a basis for consideration is absurd.

It will become apparent in what manner these principles affect the establishment of a proposed plan in America as we unfold the actual steps taken in establishing Associated Medical Services Incorporated in Ontario.

(*To be concluded*)

Correspondence

State Control in Medicine

SIR,—You publish in the *Supplement* of December 2 (p. 231) a letter signed by the Presidents of the three Royal Colleges in which is given an assurance that there is no intention on the part of the Ministry of Health to use the present Emergency Medical Service as a step towards a post-war State Medical Service. Encouraging as this is to those of us who would regret such a step, the assurance is surely based on the assumption that this same Ministry and, indeed, this same Government will be in office when the war is over. Whatever may be the case we must keep before us the possibility that sooner or later a political group for the time being in power may yet seek to introduce a State Medical Service. That great hospitals can be moved out into the country—perhaps no bad thing either for patients or for teaching—and that members of their honorary staffs can abruptly forsake private practice for salaried appointments under the Ministry of Health are already proven. This present emergency may be the precedent for the establishment of a State Medical Service.

The letter further expresses the view that there is no reason to doubt but that the voluntary system will continue. One hopes that this does not necessarily imply that we should wish to go back to the voluntary system as we have known it. The negotiations recently concluded with the Ministry of Health bring into being a system of part-time employment for consultants, with freedom to continue private practice, which must commend itself to the majority of consultants. It is, moreover, a plan which would be eminently fair to them as a peace-time arrangement. It is a fundamental change which is, I believe, in accord with the policy of the British Medical Association, and there would appear to be no very good reason why we should ever go back to the idea of honorary service inherent in the voluntary system. It is not necessary here to recapitulate the traditional arguments in favour of the voluntary system, nor need one nowadays have to try to justify change. We need only remind ourselves that the voluntary hospitals no longer serve only the sick poor, that the difference between the poor and the well-to-do is less easily distinguishable these days, that the efficiency of the hospitals themselves has for years been impaired, and increasingly so, by serious financial embarrassment. By contrast we may readily acknowledge the remarkable efficiency of a subsidized hospital service such as that of the London County Council.

Full State control would be an evil thing in medicine, yet, so far as our hospitals are concerned, it is hardly to be avoided unless we ourselves can effect a complete change of attitude towards the system we have cherished up to the present time. To-day, I suppose, the mainstay of hospital finance is the contributory scheme; there are, in addition, the various financial trusts that have been created. With the levelling of the incomes of the people has come a change in the sources from which the voluntary hospitals derive theirs. Each seems to have its own contributory scheme, often competitive and overlapping, and the vast majority of people must belong to one or another. It would be but a short step to a single nation-wide system of individual contributions, allied perhaps to the national health insurance scheme and extended, in accordance with the Association's policy, to the dependants of insured persons and those of like economic status. Financially controlled by the State, given added stability by its aid, yet administered as now by boards of management, trustees, medical committees, or other bodies constituted for the purpose, such a scheme need in no way interfere with the prestige or dignity or individuality of our hospitals, would give fresh impetus to their work, and at the same time remove the spectre of a full State Medical Service.—I am, etc.,

Buntingford, Dec. 7. ALAN WIGFIELD.

Senior Students at First-aid Posts

SIR,—A number of senior medical students are on full time service at London hospitals which are converted into first-aid posts. They are employed under the Ministry of Health. In September the Ministry decided that these young men should not receive any pay for their services, but that they should be fed at Government expense. I understand that on January 1 this concession is to cease and that from that date these students are to provide their own board and lodging.

Weekly wages are being paid to first-aid men and stretcher-bearers who cannot be as skilled in their duties as the students. I consider that the least the Government can do is to provide these young men with board and lodging, and I suggest that the British Medical Association might use its influence on their behalf. We are all of us hard hit by present conditions, and many parents experience a difficulty in meeting the expenses of their sons' education.—I am, etc.,

Dec. 11. ONE OF THE MANY PARENTS.

SCHOOL HEALTH SERVICES

The circular issued by the Board of Education and Ministry of Health urging full resumption of the school health services throughout the country, and particularly an intensive effort to provide for supervision of the health of children in the evacuation areas, is to be welcomed. As the circular states, many of the children in the evacuation areas have been without supervision or medical care for over four months. It has been agreed between the Ministries of Health and Home Security that school medical officers and nurses, and school clinics and feeding centres which were taken over for civil defence purposes, shall, where possible, be wholly or partially released for the work of the school health service, provided that they are immediately available for casualties if the occasion should arise. They have also agreed that the staff and premises of first-aid posts not previously used by the school health services, and of bathing facilities provided for A.R.P., may be utilized for the children. In this way the Government hopes to make it possible for the million children left in the evacuation areas to be inspected, bathed, and, where necessary, treated within the next three months. These arrangements are to come into operation immediately without waiting for the schools to reopen, and should cover all children of school age in the evacuation areas. The survey will also cover the nutrition of the children, and, where necessary, authorities are urged to provide supplementary nourishment. A similar effort, the circular states, should be made in neutral areas where the schools have been closed pending the completion of air raid precautions, and local education authorities in reception areas should provide for evacuated children a school medical service of the same scope and standard as that provided for local children. The school medical service, which has been built up with much labour during the last thirty years, and forms a valuable part of the educational system of this country, must not, the circular concludes, be allowed to lapse because of the stress of war.

The Government has decided that, subject to suitable accommodation being available in the reception areas, further opportunities shall be provided for women who are approaching the end of their pregnancy to leave London. The L.C.C. is to act as the co-ordinating authority, and medical officers of health of metropolitan boroughs and others concerned have been asked to obtain particulars of all such women who wish to be evacuated. Adequate arrangements have been made in the reception areas for ante-natal attendance, and, so far as possible, confinements will take place in hospitals or maternity homes. After the lying-in period the mother will be billeted according to the arrangements made by the receiving authority.

Naval, Military, and Air Force Appointments

ROYAL NAVAL MEDICAL SERVICE

Surgeon Lieutenant-Commander W. R. S. Panckridge to be Surgeon Commander.

Surgeon Lieutenants P. K. Fraser, G. D. Wedd, W. A. S. Grant, and D. P. Gurd to be Surgeon Lieutenant-Commanders.

The seniorities of the following Surgeon Lieutenants have been ante-dated to the dates shown in parentheses: K. W. Donald, A. P. Kitchin, J. Dow, R. P. Phillips, and J. P. Corcoran (March 31, 1938); J. A. McLaren (April 2, 1938); E. M. Cochrane (May 1, 1938); C. J. W. Towers (June 1, 1938); T. J. Montgomerie (September 30, 1938).

ROYAL NAVAL VOLUNTEER RESERVE

Surgeon Lieutenant (Dental) A. B. Bateman, M.B., Ch.B., B.D.S., to be Surgeon Lieutenant-Commander (Dental).

Probationary Surgeon Lieutenants to be Surgeon Lieutenants with seniorities as indicated in parentheses: J. C. MacIntosh (October 7, 1938); H. de L. N. Davis (October 5, 1938); T. B. Snell and E. L. James (October 18, 1938).

Probationary Surgeon Lieutenants F. Bagot and A. L. Taylor to be Surgeon Lieutenants.

J. A. Chivers and J. R. H. Peat to be Surgeon Lieutenants.

To be Temporary Surgeon Lieutenants: R. Leishman, M. R. J. Behrendt, W. H. H. Jebb, C. R. G Howard, H. P. Watson, R. I. C. Bradford, J. T. McCutcheon, E. J. Yates, R. Rhydwen, A. C. Shelford, J. Cuthbert, C. C. Jeffery, H. M. Dixon, G. N. Davison, R. P. Coldrey, D. K. Black, M. A. Carpenter, A. P. Robertson, T. M. Adnams, O. J. Curl, J. Baxter, A. G. Hegarty, E. H. Minors, E. W. Rees, D. N. B. Morgan, and M. J. Freeman.

ROYAL AIR FORCE VOLUNTEER RESERVE: MEDICAL BRANCH

J. Tate to be Flight Lieutenant for the duration of hostilities.

The following to be Flying Officers for the duration of hostilities: G. L. Gryspeerdt, A. A. Butler, J. D. Ebsworth, W. Foskett, M.C., G. Hutchison, J. G. M. McMurchy, K. W. Monks, C. G. Rob, A. J. Smith, W. F. Walton, D. Wilson, and D. St. C. L. Henderson.

REGULAR ARMY RESERVE OF OFFICERS

ROYAL ARMY MEDICAL CORPS

Captain H. S. Griffith has ceased to belong to the Reserve of Officers on account of ill-health.

Lieutenant D. F. Lawson, from Dorset Regiment, to be Lieutenant, with seniority January 29, 1926.

SUPPLEMENTARY RESERVE OF OFFICERS: ROYAL ARMY MEDICAL CORPS

Lieutenant W. Shirkey has ceased to belong to the Supplementary Reserve of Officers on account of ill-health.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Sir John Jarvis, M.P., to be Honorary Colonel, R.A.M.C.

Lieutenant-Colonel J. M. Chrystie, having attained the age limit, has retired and retained his rank, with permission to wear the prescribed uniform.

Captain R. Okell has relinquished his commission on account of ill-health.

Lieutenant P. Gibbin has relinquished his commission on account of ill-health

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

L. Colebrook to be Lieutenant and promoted to the rank of Acting Colonel.

Lieutenant C. F. C. White has relinquished his commission on account of ill-health.

To be Lieutenants: R. D. I. Beggs, W. S. Nutt, A. S. Gordon, W. Dawson, G. I. Scott, A. I. C. Eland, A. Brooks, S. J. Hepworth, P. G. Scott, W. J. N. Brandon, J. I. Rice, C. F. Murison, S. R. Sinclair, A. W. Frankland, E. K. Morris, G. Gregg, E. G. Morris, J. R. Sweeting, E. T. Gilbert, K. C. Crosbie, P. A. Ashcroft, W. C. Harris, D. P. Lewis-Badgett, J. B. Bamford, E. W. Duncan, M. Herman, D. D. Keall, R. McK. Martin, A. C. Turner, J. M. Stobo, L. R. Coke, W. T. Macdonald, W. H. S. McGregor, R. H. Richardson, D. G. Sheffield, R. F. Tredre, A. de M. Severne, L. L. Ratazzi.

The surname of W. Allan is as now described and not as notified in the *London Gazette* of November 17.

To be Medical Officers with the relative rank of Lieutenant: Agnes W. Black, Doris K. Small, and Hilary S. M. Hadaway.

COLONIAL MEDICAL SERVICE

The following appointments are announced: D. A. Cannon, M.B., Ch.B., D.T.M. and H., Medical Officer, Nigeria; I. H. Marrable, M.R.C.S., L.R.C.P., and F. E. Stock, F.R.C.S., Medical Officers, West Africa; D. C. M. Macpherson, M.B., Ch.B., D.T.M., Assistant Director of Medical Services, Fiji; J. MacQueen, M.D., D.P.H., Deputy Director of Medical Services, Palestine; H. S. Townsend, M.B., D.T.M. and H., Senior Health Officer, Gold Coast.

In a circular to local education authorities the Board of Education urges the resumption as soon as possible of conservative dentistry among school children. It points out that while it was necessary in many areas to suspend this work for a period following evacuation in September, much of the work done in recent years will be wasted if that period is prolonged unduly. The circular also contains advice on, among other things, transfer of dental staff from evacuation to reception areas, emergency treatment, anaesthetics, and fees for treatment.

B.M.A.: Meetings of Branches and Divisions

BIRMINGHAM BRANCH: WEST BROMWICH AND SMETHWICK DIVISION

At the annual meeting of the West Bromwich and Smethwick Division, held on October 29, the CHAIRMAN reported on the work of the Division during the past year and explained that the ordinary work had largely given way to preparations for emergency. The protection of practices scheme had been established and was operating satisfactorily, although only to a limited extent as yet. During the year one film had been shown—namely, "The Functional Treatment of Fractures"—and Dr. F. I. Dawson (Droitwich) read a paper on hydrological methods.

The following officers were elected for 1940:

Chairman, Dr. D. Saklatvala. *Deputy Chairman*, Dr. A. Wilson. *Honorary Secretary*, Dr. J. M. Mitchell. *Representative in Representative Body*, Dr. W. H. Shilvock.

Diary of B.M.A. Central Meetings

DECEMBER

29 Fri. Journal Board, 11.45 a.m.

Postgraduate News

The Fellowship of Medicine announces the following courses of instruction for Final F.R.C.S. candidates: (1) surgical tutorial classes, twice weekly, 4.30 p.m., continuing until January 25, 1940, at the Medical Society of London, 11, Chandos Street, W. There will be no lectures during Christmas week, but they will be resumed on January 2; (2) a comprehensive course at the Royal Cancer Hospital, daily at 9.30 a.m. until 1 p.m., continuing until January 27, 1940; (3) short courses in pathology will be given in January, each course consisting of two demonstrations (in the same week) from 2 p.m. to 3.30 p.m., and each course limited to six postgraduates; (4) an evening course at St. Mary's Hospital on Tuesdays, Wednesdays, and Thursdays, at 8 p.m., continuing until January 25, 1940 (excluding Christmas week), and consisting of tutorial classes on Tuesdays and Thursdays and a clinical class on Wednesdays; (5) an operative surgery course at the Royal Cancer Hospital, at 2 p.m., January 1 to 27, 1940 (strictly limited); (6) an orthopaedic course at the Royal National Orthopaedic Hospital, Stanmore, Fridays, at 2 p.m., December 29, 1939, to January 26, 1940 (strictly limited).

Lectures and practical courses of instruction for a diploma in psychological medicine will open at the Maudsley Hospital on January 2, 1940. Part I of the course will include twelve lectures on the physiology of the nervous system by Professor S. Nevin; four lectures on physiological psychology by Dr. F. Golla; four lectures on biochemistry in relation to the nervous system by Dr. S. A. Mann; eight lectures on the anatomy of the nervous system by Professor Le Gros Clark, F.R.S., and practical instruction and demonstrations by Dr. Alfred Meyer; twelve lectures on psychology by Dr. J. M. Blackburn; ten lectures on medical psychology by Dr. Aubrey Lewis; and three lectures on the practical application of intelligence tests by Dr. C. J. C. Earl. Part II will include twenty clinical tutorial classes by Professor S. Nevin; and, from March to May inclusive, eight lectures on symptomatology by Dr. Aubrey Lewis; eight lectures on causation and on genetics as applied to psychiatry by Dr. Eliot Slater; six lectures on general treatment, excluding psychological methods, by Dr. T. Tennent; eight lectures on psychopathology and the principles of psychotherapy by Dr. Bernard Hart; clinical demonstrations (1) on the organic psychoses by Professor Edward Mapother, (2) on the functional psychoses by Dr. Louis Minski, (3) on the psychoneuroses by Dr. W. S. Maclay; four lectures on the mental abnormalities of children by Dr. Mildred Creak; six lectures on mental deficiency by Dr. A. F. Tredgold; four lectures on the legal relationships of insanity by Sir Hubert Bond; six lectures on crime and insanity by Dr. W. Norwood East; three lectures and demonstrations on laboratory methods, including the examination of the blood and cerebrospinal fluid; and six lectures and demonstrations on pathology of the central nervous system by Dr. Alfred Meyer. The fee for the whole course, Parts I and II, is £15 15s.; for Part I or Part II separately, £10 10s.; for single series of lectures in Part I, £4 4s., or in Part II, £2 2s.; for the course in neurology, £4 4s.; for single series of demonstrations, £1 1s.; special May course, £5 5s. Inquiries should be addressed to Professor S. Nevin, Honorary Director of the Medical School, Central Pathological Laboratory, West Park Hospital, Epsom, Surrey.

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this heading is 9s. This amount should be forwarded with the notice, authenticated by the name and address of the sender, and should reach the Advertisement Manager not later than the first post Tuesday morning to ensure insertion in the current issue

BIRTH

PRESTON.—On December 15, 1939, at Eastbourne, to Margaret, wife of Lieut.-Colonel T. W. Preston, M.D., R.A.M.C., a son.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY DECEMBER 30 1939

WAR NOTICE

Closing Date of Protection of Practices Schemes in Greater London

At a joint meeting of the Local Emergency Committees for London, Middlesex, South-West Essex, and Stratford, held on November 2, 1939, it was decided that no practitioners should be admitted to the Protection of Practices Schemes in the areas mentioned after December 31, 1939, except at the discretion of the Local Emergency Committee concerned. A period of grace of fifteen days has, however, been allowed, and the final date of closing will be January 15, 1940.

CENTRAL MEDICAL WAR COMMITTEE,
British Medical Association House,
Tavistock Square, W.C.1.

MEDICAL TREATMENT BY CIVILIAN DOCTORS OF MEN SERVING WITH THE FORCES

The following letter has been sent by the Ministry of Health to Clerks to Insurance Committees:

"1. A number of inquiries have been received from insurance committees on behalf of doctors on their medical lists as to the circumstances in which soldiers (including women members, other than officers, of the Auxiliary Territorial Service or Voluntary Aid Detachments) may call in the services of a civilian doctor at the cost of the funds of the War Office, and as to the steps the doctor should take to obtain payment. The Minister has been in communication with the War Office on the subject and is in a position to give the following information.

"2. For the purpose of this letter soldiers, etc., may be divided into three groups:

(*a*) Soldiers quartered in barracks or camps.
(*b*) Soldiers on leave or furlough.
(*c*) Soldiers who whilst training reside at home or in billets.

"3. No occasion will arise for soldiers in group (*a*) to apply to a civilian doctor for treatment, as a medical officer of the Army Medical Corps will be stationed at the barracks or camp.

"4. As regards group (*b*), when a soldier proceeds on leave or furlough he is supplied with a pass which instructs him, should he require medical aid, to apply at the nearest military hospital whenever practicable. In the event of the soldier living more than two miles from the military hospital, or his condition being such that he is unable to travel to the hospital, he may, at the cost of the funds of the War Office, call in a civilian doctor. The rates allowed for attendance are given on the pass which the soldier is instructed to show to the doctor.

"5. Soldiers who whilst training reside at home or in billets should apply, if they need medical aid, to the medical officer attached to their unit. In emergencies where the medical officer attached to the unit or military hospital is not available the soldier may call in a civilian doctor.

"6. To obtain payment from the War Office a civilian doctor must procure and fill in Army Form O.1667. The form must be sent on the conclusion of treatment to the Deputy or Assistant Director of Medical Services of the Command. . . . The claim may be sent to the Deputy or Assistant Director by the doctor either direct or through the Insurance Committee or Panel Committee if, as is assumed, both those committees will be prepared to undertake the collection and transmission of the claims.

"7. The Minister would be glad if the Insurance Committee would communicate at an early date with the Panel Committee with a view to the information . . . being made known to them and to practitioners on the insurance medical list. . . . A supply of Army Form O.1667 will be forwarded by the Minister to the Insurance Committee or Panel Committee on application, in order that they may deal with applications made to them by doctors who require the form in order to submit a claim.

"8. It will be appreciated that where a soldier applies to a civilian doctor for treatment in circumstances where he should clearly have had recourse to military arrangements the War Office cannot accept responsibility for payment.

"9. In the case of the Royal Air Force and Women's Auxiliary Air Force the general conditions set out above for Army personnel apply. Airmen or airwomen who have received medical attention from a civilian medical practitioner are required to report the fact immediately to their Commanding Officer and forward to him the doctor's certificate. The Commanding Officer will then furnish the doctor with a copy of Form O.1667. This form should be completed by the doctor and returned to the officer from whom it was received, who will then arrange for payment. All relevant information concerning fees, etc., is shown on the reverse of the Royal Air Force Leave Form which airmen (and airwomen) are required to show to the doctor and on Form O.1667.

"10. Men serving with the Royal Navy (including women members, other than officers, of the Women's Royal Naval Service and Voluntary Aid Detachments) can, when on leave from their ship (or depot), obtain treatment from a local civilian doctor, and when doing so should obtain a preliminary medical certificate from the doctor and send it to the Commanding Officer of their ship (or depot), who will furnish the doctor with the necessary Form (S.26) for claiming payment. It is clearly indicated in the form to whom the completed claim should be sent.

"11. It is not anticipated that the assistance of the Insurance and Panel Committees will be needed in connexion with the collection of claims for the treatment of men and women in the Royal Navy and Royal Air Force."

A copy of Army Form O.1667 has been sent with the letter. One side of this form is headed "Civilian Medical Practitioner's Bill," and provides for a statement of the patient's name and rank, nature of his illness, distance from practitioner's to patient's residence, distance from patient's residence to nearest military hospital, and whether the patient was visited or attended at the surgery. It also provides forms of certificate to be signed by the civilian practitioner, the Commanding Officer, and the Deputy or Assistant Director of Medical Services of the Command. The instructions on the reverse of the form contain the following scale of charges, and a concluding note states that the cost of medicine necessary for treatment is included in these charges:

Scale of Charges applicable for Visits made on or after September 1, 1939

1st— VISIT AND MEDICINE

Column 1	2	3	4
	Visit to surgery	If not more than 2 miles away	Greater distances
Day	s. d. 3 0	s. d. 4 6	An addition of 6d. for each additional mile or part of a mile, with a limit of £1 per visit.
Night .. .. 22.00 to 07.00	—	6 0	An addition of 6d. for each additional mile or part of a mile, with a limit of £1 for ordinary visits. In very exceptional circumstances the {G.O.C. / A.O.C.} may, if he considers the fee admissible on this basis inadequate, refer the case to the {War Office / Air Ministry}, when payment at a higher rate will be considered. He should furnish full particulars, including time of night, duration of the visit, and nature of the case.

The "Distance Fee" is payable in one direction only, and is payable in respect only of the first case visited, when more than one patient is attended in the neighbourhood on the same occasion. The fee shown in column 3 will be allowable for each patient after the first, subject to the maximum limit of £1 17s. 6d. a day for all services.

2nd—Charges for surgical appliances, when necessary, will be allowed by the {War Office / Air Ministry} according to circumstances.

3rd—Minor surgical operations (including revaccination): Each case, 2s. 6d.

4th—For other operations, and for special cases, remuneration as fixed by the {War Office / Air Ministry} will be allowed according to circumstances and nature of case.

IMPLICATIONS OF HEALTH INSURANCE IN AMERICA

BY

J. A. HANNAH, M.D.

Managing Director, Associated Medical Services Incorporated, Toronto

The following is the second and concluding part of Dr. Hannah's article. The first appeared last week at page 245.

In approaching this problem it would appear that there are three main methods by which we may achieve our goal: (1) by legislation; (2) as an ordinary business project; and (3) through co-operation of all interested parties.

A legislative Act is the written, considered opinion of the party in power in regard to any particular problem. The Act may be conceived and drafted with every good intention and may contain what appears at the moment to be the best arrangement and regulations possible. Having set its opinion in writing no political body can afford to change that opinion with any degree of alacrity, even if it were possible to convince sufficient members. In addition, it would appear that there can be no gradual period of development in either growth or experience. Up to the moment such an Act becomes effective there would be no insured; immediately following its effective date there may be hundreds of thousands or even millions under its administration. Try as we will, satisfactory provision cannot be made for its administration. Inexperience will give rise to mistakes, and mistakes on the scale of hundreds of thousands and millions are costly.

Again, who among the profession or the public cares what the Act is or stipulates during a period of illness—the patient must be served and the Act be hanged. The very inelasticity of well-intentioned Acts renders them impractical in regard to medical practice except in so far as they are purely enabling. The inherent dangers of political control have been all too manifest in the mental hospitals in both the U.S.A. and Canada to need further comment here.

The second approach is through the usual channels of business. Business methods and economic laws must be observed, except that the experience of sickness and accident insurance companies has shown that the profit motive destroys the effectiveness of this form of insurance and fails to meet the needs of illness. Any portion of illness which is not profitable to the insuree is either not covered or is excluded from the policy at the first opportunity. The profit motive has stipulated that the male wage-earner can be insured at half the cost of the female earner. The male adult in the family is profitable and therefore can be insured. The wife and children are not profitable, therefore they cannot be covered.

Illness has no regard for persons: male or female, young or old, healthy or unhealthy, rich or poor. Therefore, the profession can have no truck or trade with any plan which does not aim at meeting the cost of illness as we find it in the family units, without regard to whether there is profit to any shareholder. We have, however, a very vital interest in how such services can be paid. Therefore, it becomes imperative that we observe the law of supply and demand. Let us not, however, be deceived. No amount of Government patronage out of taxation can remove any portion of the cost to the public or meet the public's responsibility, except in so far as it meets its fair share of the cost of the indigent or the near-indigent.

Co-operation

Realizing these factors, and in the light of the foregoing studies, the medical profession in the province of Ontario set about the development of our answer to this problem. From here on we shall deal with the formation, organization, and growth of Associated Medical Services Incorporated in Ontario.

In 1930 I became a member of the Ontario Civil Service Association. Shortly afterwards the association became interested in some form of health protection for its members. Consideration was given to hiring a staff of physicians and making a contract with some hospital to give service. This, however, did not appear to me to provide the type of service desired, and so I was appointed to a committee to report back with a plan which might prove to the liking of both the civil servants and the medical profession. This was done at the annual meeting in 1933. The committee was given an appropriation and continued its studies, most of which have already been given.

At the annual meeting in 1934 the association gave its approval to the plan which later developed into Associated Medical Services. Among other principles laid down were: (1) that the choice of physician was desirable; (2) that the medical profession should control the method of practice; and (3) that we should accept the Ontario Medical Association's schedule of fees as being fair and proper. Such proposals naturally presuppose the co-operation of the profession, and so it fell to my lot to approach the Academy of Medicine in Toronto, of which I had been a member for some years. The Academy preferred to refer the matter to its parent body, the Ontario Medical Association, and this was done at its annual meeting in 1936.

Now it is of interest that the Ontario Medical Association had been studying the problem of compulsory health insurance under the able chairmanship of Dr. W. S. Caldwell. A resolution was passed favouring the principle of a voluntary plan and a committee set up to study the institution of trial areas in the province. On January 14, 1937, the insurance committee delegated authority to five of its members to: (1) Draft a constitution and by-laws. (2) Place these before the Board of Directors of the Ontario Medical Association. (3) Ascertain the cost of instituting the plan. (4) Obtain the necessary finances. (5) Take out a charter and go into operation.

Ten days before February 23, 1937, the executive bodies of the Ontario Medical Association had the constitution and by-laws in their hands, and at their meeting on that date they not only approved of the setting up of the plan but gave an initial grant of $5,000 for the institution of the plans. It is of interest to note that unanimity did not prevail. The profession in the city of Windsor insisted that the plan should be started on a group industrial basis, whereas Toronto was prepared to start with single individuals. It is of further interest that Windsor has not gone into operation yet,[*] while Toronto has 6,000 subscribers, and branches in Ottawa, Oshawa, Hamilton, and Woodstock.[†] Out of the $5,000, Windsor got $1,200, which latter sum was advanced by the Civil Service Association. It is to be noted that $5,000 constitutes the total amount of money advanced for organization outside which all our expenses, administrative and medical, have been met from income.

Following this degree of approval the Civil Service Association decided to cast in its lot with the province-wide plan, and a charter was secured from the Ontario Government on April 9, 1937, under the name of Associated Medical Services Incorporated. On June 1, 1937, we opened our offices at 11, Queen's Park, Toronto, in space granted rent-free by the Government. At the close of 1937, after seven months' operation, we had secured 733 subscribers and were paying most of our overhead, as well as showing a surplus of $1,722 on our medical reserve account.

During 1938 our subscribers rose to 4,020—five and a half times the number with which we ended 1937. At the same time our reserve increased almost eight times, leaving sufficient funds to carry our previous experience for three months without income, if necessary. We closed the year with a surplus of $160 in our administrative account and $11,000 dollars in our medical reserve account. Since December 31, 1938, we have had 2,500, or 60 per cent., increase in subscribers.[‡] Both medical and administrative reserves are showing healthy increases.

Scope and Terms of the Service

You will no doubt be interested in knowing the services we give, the subscription we collect, and the schedule of fees we allow our participating physicians. The following are extracts from our regulations:

> The Corporation shall provide to the subscriber the following benefits upon the terms and under the conditions as set forth in the regulations. The benefits to the subscriber shall be limited to services and treatment to be provided by a participating physician in any branch area, provided that the Corporation will in their discretion defray the whole or any portion of the expenses incurred in the treatment of the subscriber outside such branch area.

1.—*Medical benefits:*

Medical benefits shall be deemed to include:

(*a*) All medical attention necessary for diagnosis and treatment of illness, whether in the home, office, or hospital, including accidents. Obstetrics shall also be included provided that the obstetrical patient's husband must also be a subscriber and both must have been subscribers for ten consecutive months before delivery.

The cost of hospital care at the rate of $1.00 a day will be provided for the child up to 14 days after birth, after which time application may be made to include the child as a dependant in accordance with the regulations.

(*b*) Such *x*-ray services as shall be deemed necessary for the proper diagnosis and treatment of the subscriber.

(*c*) The cost of anaesthetics and their administration.

2.—*Surgical benefits:*

Surgical benefits shall be deemed to include:

All procedures and practices usually considered within the scope of a competent surgeon, but shall not include the treatment of conditions not detrimental to bodily health or interfering with function.

3.—*Consultant service:*

A consultant may be called through the Branch Medical Officer, either at the request of the participating physician or the subscriber.

4.—*Hospital benefits:*

Hospital benefits shall be deemed to include:

(*a*) Available semi-private accommodation in a hospital approved by the Corporation, the cost of which does not exceed $3.50 per day.

(*b*) Cost of anaesthetics and operating room.

(*c*) Such medicines as shall be required while in hospital not to exceed the sum of fifty cents (50 c.) per day.

5.—*Nursing benefits:*

Nursing benefits shall be deemed to include such nursing as shall be deemed necessary by the Branch Medical Officer.

6.—*Sanction for service:*

Where the services required are such as are not usually supplied by a general practitioner the approval of the Branch Medical Officer is required. For example: Consultations, major surgery, technical diagnostic procedures, *x*-ray, hospitalization, nursing care, etc.

7.—*Total amount of service paid for:*

The Corporation shall be liable for the expense of service under this contract to a sum not exceeding eight hundred dollars ($800.00) in any consecutive twelve-month period and for each subscriber or dependant.

Services excluded:

(1) The Corporation shall not be responsible for the care of, or any expense in connexion with the care of, institutionalized epilepsy, institutionalized mental diseases, institutionalized feeble-mindedness, institutionalized tuberculosis, nor for venereal diseases nor any disease or injury arising from any accident covered by the Workmen's Compensation Act, nor for the care of any subscriber suffering from any disease or injury arising from any condition for the expenses of which the Ontario or Dominion Government or any other body is responsible.

(2) The Corporation shall not be responsible for any expense incurred by reason of any condition which existed at the date of application of the subscriber.

Family group rates of subscription:

In order to maintain the family group rate all members of the immediate family must make application to become subscribers. If the Corporation declines one or more applications from the group the family rate shall still apply, provided all of the accepted members of the family remain subscribers.

The subscriber shall pay or cause to be paid on his behalf to the Corporation in advance monthly subscriptions on the following scale:

For the subscriber	$2.00 per month
For the first dependant of the subscriber	1.75 per month
For the second dependant of the subscriber	1.50 per month
For the third dependant of the subscriber	1.25 per month
For the fourth and each additional dependant of the subscriber	1.00 per month

Individual subscription rate:

The individual rate of subscription shall be $2.00 per month per subscriber and shall be the rate in all cases where the family group rate does not apply.

---

[*] Windsor Medical Services, Incorporated, announced the inauguration of its plan on July 8, 1939.

[†] Since the date of writing we have grown to 9,000 subscribers. In addition we have passed through the recent epidemic of influenza and at the same time a particularly heavy epidemic of measles, despite which we show a reasonable increase in our medical reserve.

[‡] Since December 31, 1938, to date of writing (August 11, 1939) we have had an increase of 4,815 subscribers.

Waiting period:

> The subscriber shall be entitled to benefits herein provided from the date set forth upon his identification card (Form No. 5), which shall be two months from the first day of the month nearest the date of his application.*

Schedule of fees:

> The schedule of fees allowed shall be that designated by the Ontario Medical Association and in force at the time the service is rendered.

In arriving at a basis of service and its cost we have considered it best to set out the services required by an individual in one year† and set against them the cost on the basis of the minimum schedule of fees as given in the tariff of the Ontario Medical Association. This appears as follows:

Home calls—1 per person per year	$3.00
Office calls—1.5 per person per year at $2.00 ..	3.00
Surgical operations—0.08 per person per year at $50.00	4.00
Consultations and specialist cost per person per year	4.00
X-ray and laboratory work	1.00
Hospitalization—1.3 days at $3.50	4.50
Nursing—0.5 day at $5.00 per day	2.50
Administration	2.00
Total	$24.00

These services cover obstetrical and surgical attention under controlled conditions, and the cost totals $24.00 per person per year in the individual situation. Because of the reduced incidence of service required in the family situation the cost drops twenty-five cents for each dependant to a minimum of $1.00 per person. In the average family of four this costs $6.50 per month, or $5\frac{12}{32}$ c. per day per person. This is less than is spent annually by such average family on tobacco, cosmetics, or other luxuries.

Personally I am a firm believer in democracy, and to me democracy means not only personal liberty but also personal responsibility. Every time we shirk our personal responsibility by handing it over to Governments, just so often do we dole out a corresponding portion of personal liberty. I believe we can answer the problem better in our own way through an evolution of gradual growth; raising a structure flexible to our needs, growing into the shape and moulded to the need of medical service; carrying with us all that is good out of the past; disregarding useless and dead wood; and adhering ever and always to the most sacred of all, the Hippocratic Oath.

---

* To this has been added: "except in the case of the removal of tonsils and/or adenoids, in which case the waiting period shall be twelve months from the date of application."

† The figures for service are the result of wide study and research over a period of four years and are drawn from sources too numerous to list.

Naval, Military, and Air Force Appointments

ROYAL ARMY MEDICAL CORPS

The appointments of Lieutenants F. B Bagshaw and H. I. A. Richards have been antedated to November 4 and 5, 1937, respectively, under the provisions of Article 36, Royal Warrant for Pay and Promotion, 1931, but not to carry pay and allowances prior to November 1, 1938. (Substituted for the notification in the *London Gazette* of November 28.)

The temporary commission of Lieutenant J. McN. Campbell has terminated.

ROYAL AIR FORCE MEDICAL SERVICE

Flying Officers to be Flight Lieutenants, with seniorities indicated in parentheses: J. E. Furness and R. V. Wright (September 12, 1938); I. Shaw (November 7, 1938).

Flying Officers D. Macdonald and F. D. Campbell to be Flight Lieutenants.

AUXILIARY AIR FORCE: MEDICAL BRANCH

Flying Officer W. W. Walker to be Flight Lieutenant.

T. G. Davies and C O. Hudson to be Flying Officers.

ROYAL AIR FORCE VOLUNTEER RESERVE: MEDICAL BRANCH

M. Pearson has been granted a commission as Flight Lieutenant for the duration of hostilities. (Substituted for the notification in the *London Gazette* of December 5.)

To be Flying Officers for the duration of hostilities: J. T. Burrowes and T. V. Mendlesohn.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Major G. G. Marshall has relinquished his commission on account of ill-health

Major J. A. Bruce, from Territorial Army, Royal Artillery, to be Major, with seniority July 15, 1937.

Lieutenant D. Arnott, from Territorial Army Reserve of Officers, General List, Royal Artillery, to be Lieutenant.

TERRITORIAL ARMY RESERVE OF OFFICERS: ROYAL ARMY MEDICAL CORPS

Captain A. C. Frazer, from Active List, to be Captain.

LAND FORCES: EMERGENCY COMMISSIONS

To be Lieutenants: F. L. Cane, J. A. Finegan, R. Paul, J. L. Chisnall, D. J. Cusiter, D. G. C. Whyte, J. A. Sinclair, D. W. F. Gotla, G. N. Barker, R. T. Wordingham, D. W. Benyon, H. D. E. Whitman, E. G. Holmes, W. S. Brindle, A. Amdor, B. W. Thompson, M. C. Fulton, S. Widman, F. B. Akeroyd, G. W. Blenkinsop, G. Wilson, R. J. House, H. A. Gibb, A. Bickford, G. A. H. Adam, W. J. C. Auld, J. T. Boyd, G. B. Carter, S. R. E. Davies, J. L. M. Jeffares, J. S. Jeffrey, T. G. Martin, R. G. Miller, R. Traill, A. F. Turner, F. H. Taylor, A. J. Leslie-Spinks, T. H. Bassett, W. Brown, D. E. Rodger, R. E. S. Dalliwall, W. E. M. Mitchell, M.C., B. Geneen, T. Lynch, G. Struthers, J. McD. S. Slater, G. H. Smith, J. N. Barber, N. R. Hill, and C. F. Morrison.

Fanny Pollecoff and Anna R. Glover to be Medical Officers with the relative rank of Lieutenant.

INDIAN MEDICAL SERVICE

The Secretary of State for India has appointed to the Civil Branch of the Indian Medical Service the following officers of the Indian Medical Service, with effect from the dates indicated in parentheses: *Central Government:* Captain C. J. Hassett (January 3, 1939); Major G. Milne (January 18, 1939); Major J. H. Gorman (February 6, 1939); Captain H. W. G. Staunton (March 28, 1939); Captain T. Sommerville (May 30, 1939). *Madras:* Captain S. Shone (January 17, 1939). *United Provinces:* Captain A. B. Guild (January 14, 1939); Captain T. F. O'Donnel (April 6, 1939). *Punjab:* Captain D. W. Taylor (June 1, 1939). *Bihar and Orissa (Joint Cadre):* Captain A. D. Andreasen (April 30, 1939); Captain J. D. Murdoch (May 9, 1939)

Lieutenant-Colonel R. F. D. MacGregor, C.I.E., M.C., has been advanced to the List of Special Selected Lieutenant-Colonels.

Postgraduate News

The Fellowship of Medicine announces the following courses of instruction for Final F.R.C.S. candidates: (1) surgical tutorial classes twice weekly, 4.30 p.m., continuing until January 25, 1940, at the Medical Society of London, 11, Chandos Street, W. The lectures for this week are on diseases of bones by Mr. R. J. McNeill Love on January 2, and on injuries to bones by Mr. A. M. A. Moore, January 3; (2) a comprehensive course at the Royal Cancer Hospital, daily from 9.30 a.m. to 1 p.m., continuing until January 27, 1940; (3) short courses in pathology, each course consisting of two demonstrations (in the same week) from 2 p.m. to 3.30 p.m., and each course limited to six postgraduates; (4) a course at St. Mary's Hospital, Tuesdays, Wednesdays, and Thursdays, at 8 p.m., continuing until January 25; (5) an operative surgery course at the Royal Cancer Hospital at 2 p.m., January 1 to 27; (6) an orthopaedic course at Royal National Orthopaedic Hospital, Brockley Hill, Stanmore, Fridays, at 2 p.m., until January 27.

WEEKLY POSTGRADUATE DIARY

FELLOWSHIP OF MEDICINE AND POSTGRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.—*St. Mary's Hospital*, Paddington, W.—Tues., Wed., and Thurs., 8 p.m., Final F.R.C.S. Clinical and Tutorial Course. *Royal Cancer Hospital*, Fulham Road, S.W.—Daily, 9.30 a.m. to 1 p.m., Comprehensive Final F.R.C.S. Course. Mon., Thurs., and Fri., Operative Surgery Course. *Medical Society of London*, 11, Chandos Street, W.—Surgical Tutorial Classes, Tues., 4.30 p.m., Mr. R. J. McNeill Love, Diseases of Bones; Wed., 4.30 p.m., Mr. A. M. A. Moore, Injuries to Bones. *Royal National Orthopaedic Hospital*, Brockley Hill, Stanmore.—Fri., 2 p.m., Orthopaedic Course.

VACANCIES

EXAMINING FACTORY SURGEON.—The appointment at Lincoln is vacant. Applications to the Chief Inspector of Factories, Home Office, Whitehall, S.W.1, by January 10, 1940.

Diary of B.M.A. Central Meetings

DECEMBER

29 Fri. Journal Board, 11.45 a.m.

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this heading is 9s This amount should be forwarded with the notice, authenticated by the name and address of the sender, and should reach the Advertisement Manager not later than the first post Tuesday morning to ensure insertion in the current issue

BIRTHS

KANAAR.—On December 2, at High Salvington, Sussex, the wife of Lieutenant A. C Kanaar, R.A.M.C.—a son.

PARFIT.—On December 20, at the West China Union University, Chengtu, Szechuan, to Jessie (*née* Browne), M.D., and Norman Parfit, B.M., B.Ch., D.P.H.—a daughter.

INTRACRANIAL CAUSES OF HEADACHE *

BY

HENRY COHEN, M.D., F.R.C.P.

Professor of Medicine, University of Liverpool; Honorary Physician, Royal Infirmary, Liverpool, etc.

Causes of Head Pains

The causes of pains in the head are customarily, and for diagnostic purposes conveniently, grouped on an essentially anatomical basis:

1. *Intracranial*—namely, diseases of the brain and meninges.
2. *Cranial*—namely, diseases of the skull bones and the enclosed air sinuses.
3. *Extracranial*—namely, diseases of the scalp. For example, fibromyositis of the occipito-frontalis muscle or its aponeurosis: trigeminal, spheno-palatine (Sluder's), and occipital neuralgias; herpes supra-orbitalis; temporal arteritis, etc.
4. *Reflex*, from diseases of the eyes, teeth, and nose, though nasal causes might produce their effect through the air sinuses —for example, by inflammatory changes spreading to them or the production of so-called "vacuum" headache.
5. *Toxic*: the source being (*a*) exogenous—for example, alcohol, tobacco, lead, poisonous fumes, CO_2, etc.; or (*b*) endogenous—for example, uraemia, constipation, fevers.
6. *Migraine*: an incomplete diagnosis signifying a syndrome —that is, a constantly recurring group of symptoms—which is the clinical expression of a disturbed mechanism common to many pathological states. It merits a separate category because the syndrome itself is significant even when the exciting cause remains unmasked (cf. epilepsy).
7. *Psychogenic*—occurring in psychoneuroses, psychoses, and exhaustion states.

This paper is concerned chiefly with the first and sixth groups. Let me stress at the outset that headache is a symptom unaccompanied by specific physical signs capable of quantitative assessment. Hence in any given case in which headache is the presenting symptom we are dependent on the patient's descriptive powers for a knowledge of: (1) its *site and duration*, which are often vague, especially in retrospect; (2) its *character*, including its quality; its mode of onset and decline; whether it is constant, intermittent, or subject to paroxysmal exacerbations; the circumstances which aggravate or alleviate it—an accurate description of which often defeats the verbal resources of even the more intelligent of patients; and (3) its *intensity*, which varies not only with the severity and rate of development of the cause but also with the patient's threshold for pain—the same noxious stimulus in one patient producing "slight headache," in another "excruciating pain." Hence the patient's account of headache may be of little diagnostic value, and it is not surprising that a recent annotation in the *British Medical Journal* (May 6, 1939, p. 929) should speak of headache as "a symptom which has for long been one of the commonest, most unintelligible, and most intractable with which the practitioner has to deal." While it is true that few human beings can claim never to have suffered from headache, recent advances in therapeutics, both medical and surgical, have rendered many types more amenable to treatment, and recent observations, both experimental and clinical, have thrown considerable light on the mechanism of production of headache. This knowledge is of fundamental importance for a proper understanding of the problem under discussion. It is to-day beyond reasonable doubt, for example, that the mechanism of cardiac pain is the same—myocardial anoxia—whether the pathological cause be coronary thrombosis, angina of effort, myocardial fibrosis, or profound anaemia. If it could be demonstrated that the mechanisms of headache were similar, whether brought into play by a systemic disturbance such as fever, or local intracranial lesions such as injury, inflammation, tumours, etc., we should then be led to the significant conclusion that there is no type of headache which is of itself pathognomonic of an intracranial lesion, and we should have to look to other characters of the headache—its site, intensity, mode of evolution, the circumstances which affect it, and associated symptoms and signs—to suggest not only its intracranial origin but the nature of the causative lesion. To examine this problem as it affects all head pains exceeds the scope of our immediate inquiry. I propose, therefore, to confine myself to a consideration of certain pertinent questions.

1. How often does Headache indicate Organic Nervous Disease?

Physicians with differing special interests will give widely varying answers to this question. Spriggs found organic nervous disease in twenty-six out of 500 patients with chronic headache. Of my last 500 patients in whom headache was a dominant symptom, ninety-six were suffering from organic nervous disease. Doubtless the neurologist would find an even larger proportion among his patients. It is thus only a relatively small number of sufferers from chronic headache who are the victims of organic intracranial disease.

---

* Read in opening a discussion in the Section of Neurology and Psychiatry at the Annual Meeting of the British Medical Association, Aberdeen, 1939.

2. Of what Intracranial Lesions is Headache a Common Presenting Symptom ?

At some time in their evolution all intracranial lesions may be associated with headache. In some, however, headache is a dominant and often the presenting symptom; in others it is merely incidental and overshadowed by other symptoms and signs. For reasons which will become clearer as our argument develops it is useful to classify the former group as follows:

Group I.—Those which trespass on the space occupied by normal intracranial structures ("expanding lesions"): (*a*) "*tumours*"—namely, neoplasms, cysts, abscesses, aneurysms, granulomata, subdural haematoma, hyperostosis interna frontalis, etc.; (*b*) *swelling of the brain itself* due to oedematous and inflammatory changes (for example, encephalitis, disseminated sclerosis, etc.), vascular lesions such as haemorrhage and thrombosis, injuries with resulting haemorrhages and oedema.

Group II.—*Meningeal irritation*, by inflammatory exudate (that is, meningitis of all types, whether acute or chronic), haemorrhage into the subarachnoid space, and cancer cells (as in meningitis carcinomatosa).

Group III.—*Disease of the cerebral arteries*—cerebral arteriosclerosis, syphilitic endarteritis, hypertension, etc.

Group IV.—A miscellaneous group with no demonstrable gross pathology—for example, post-traumatic headaches, migraine, and epilepsy.

Much overlapping will be detected in this grouping. A cerebral tumour is not infrequently associated with haemorrhage and oedema; trauma with a subdural haematoma or intracerebral haemorrhage, and so forth.

In relation to this classification three points are worth stressing. First, that the more rapid the development of the causative pathological lesion the more intense is likely to be the accompanying headache. Secondly, that the earlier and more marked the interference with the circulation of the cerebrospinal fluid, the earlier in onset and more intense is the associated headache. For example, while headache is the presenting symptom in 90 per cent. of patients suffering from tumours of the posterior fossa, in only 33 per cent. of supratentorial tumours is it the initial complaint. The former early obstruct the outflow of cerebrospinal fluid from the fourth ventricle and cause internal hydrocephalus. Moreover, patients with temporal lobe tumours, which more easily disturb the third ventricle, complain of headache as their initial symptom much more frequently than patients with frontal lobe tumours, where the circulation of the cerebrospinal fluid is unlikely to be disturbed in the early stages. And thirdly, whilst in adults the skull is a closed and, for all practical purposes, an inexpansile box, in children expansion of the cranium is possible before closure of the sutures, hence space-occupying lesions may not so grossly disturb intracranial pressure relations.

Before considering the significance of our classification, let us turn to the third question.

3. What Varieties of Headache may be Found Associated with Intracranial Pathology ?

There are four varieties of headache commonly complained of by patients suffering from intracranial disease.

Type 1.—A pain vaguely described as dull or throbbing, but sometimes as a "sharp stab," "bursting," or "splitting" pain. It is usually felt "inside the head," and the localization is indefinite, though during an attack, which is the best time to determine its site, it may be described as unilateral, frontal, occipital, or temporal. It is usually worse on waking, and careful questioning will often reveal that the exciting factor at this time is the sudden turning over in bed or sitting up. Its most characteristic feature is its aggravation by coughing, sneezing, stooping, or straining at stool, and often each pulsation of the heart, or on walking each step, gives a "thump in the head." Usually jugular vein compression aggravates though carotid artery compression eases the pain. It may be constant or intermittent, but paroxysmal exacerbations occur, and with these projectile vomiting is not uncommon. *This type of headache is complained of most commonly in "expanding lesions" of the brain.* Even when remote areas of the brain are affected the pain is usually referred to the forehead. If unilateral it is on the same side as the lesion in about 75 per cent. of cases; in 10 per cent., however, it is referred to the side opposite to the lesion. Occasionally we encounter attacks of sudden excruciating generalized pain "as if the head were going to burst." These come like a bolt from the blue and attain their maximum intensity within a few seconds, during which time the patient is quite uncontrollable and not infrequently semi-conscious. The attacks last a varying period, from a few seconds to a few minutes, and disappear quite rapidly. They are sometimes accompanied by vomiting and are usually followed by profound exhaustion. From such descriptions as I have been able to elicit this type of attack is simply an acute and intensely severe, if transitory, exacerbation of the type above described. Though rare, it is almost invariably associated with tumours, especially of the posterior fossa, and is a symptom of grave import because it indicates foraminal or tentorial crowding.

Type 2.—A sharp pain at the back of the head and radiating down the back of the neck, but which is referred also to the temporal and frontal regions and is accompanied by rigidity of the retronuchal muscles. It is aggravated by movements of the head and attempted flexion of the neck. This type of pain is seen in its most acute and severe form in basal subarachnoid haemorrhages which extend into the posterior fossa and irritate the medulla and upper cervical cord. It is also an almost constant accompaniment of all forms of meningitis. It occurs in about 50 per cent. of posterior fossa tumours and in about 25 per cent. of supratentorial tumours. Occipital neuralgia and neuritis are associated with a similar type of pain. In occipital neuralgia, however, there is a long-standing history of paroxysms of shooting pains with completely free intervals; neither neck rigidity nor fronto-temporal radiation of the pain accompanies a simple neuralgia. Where, however, an occipital neuritis results from vertebral disease or cervico-occipital fibromyositis, though the accompanying pain has neither frontal nor temporal radiation, limitation of neck movements might be present. This rigidity, however, differs from that of meningeal irritation both in its type and in its extent. The rigidity of meningeal irritation is confined to the extensor muscles of the neck, giving rise to neck retraction and to Kernig's and Brudzinski's signs; vertebral rigidity limits neck movements in all directions; fibromyositis causes pain on attempted stretching of the affected muscles. Moreover, the local tenderness and other evidences of spondylitis and fibromyositis serve easily to distinguish meningeal from extracranial causes of neck rigidity.

Type 3.—The *migrainous* type of headache—namely, a recurring paroxysmal headache often, though not necessarily, unilateral, accompanied by nausea, vomiting, dizziness, and frequently preceded by disturbances of vision or other sensory and motor aurae. Between the attacks the patient is free from headache, but during the attack the *pain corresponds to that of Type 1.*

A fourth type, which not infrequently accompanies pituitary tumours, is that of a dull ache, usually frontal and temporal, rarely spreading to the occiput, and associated with *neuralgic pains radiating to the eyes, eyebrows, or face.* This neuralgic element is thought to be due to direct involvement of the upper roots of the fifth nerve. Its first component does not differ from the pain described as Type 1; hence it does not merit differentiation into a separate type, and we can therefore limit our clinical description of the headache found in intracranial lesions to three types.

Correlation of Types and Lesions

When we tabulate these types and the intracranial lesions with which they are associated, a significant correlation becomes evident. Type 1 is commonest in Group I lesions—the "space-trespassing" group; Type 2 in Group II lesions—the "meningeal irritation" group. Type 3 is commonest in vascular lesions, especially intracranial aneurysms, cerebral arteriosclerosis, hypertension, and the migraine of allergic, endocrinous, biliary, etc., origin. All three types of headache (and this is to be specially noted in regard to migraine) are consistent with, though not necessarily indicative of, gross intracranial pathology. All types have been found on occasion associated with cerebral tumours, abscesses, encephalitis, thrombosis, head injuries, etc. Yet all have occurred in the absence of demonstrable cerebral pathology, thus suggesting that the essential mechanisms are functional and not dependent on an irreversible structural change.

The mechanism of Type 2 headache is clearly related to irritation of the meninges: a knowledge of the nerve supply to the meninges and meningeal vessels suggests that pain is referred to the skin areas supplied by the same sensory nerves (frontal, facial, and temporal pain arising from the fifth nerve which is distributed to the anterior and middle fossae; occipital and retronuchal pain from the upper cervical roots which supply the posterior fossa) and that the accompanying retronuchal rigidity owes its origin to an accompanying sensori-motor reflex. Direct irritation from pressure of the brain (for example, in internal hydrocephalus), or of a tumour itself, might cause similar "meningeal" pain. This type of pain can, as Northfield suggests, be regarded as analogous to somatic pains elsewhere in the body in that their characters (sharp, stabbing, and continuous) are similar and accurate localization is in both cases possible (cf. the pain of peritonitis, pleurisy, and pericarditis). When we analyse migraine (Type 3) we find that the headache component corresponds in all respects to Type 1. What serve to differentiate migraine as a syndrome are the aurae, the paroxysms, the common hemicrania, the short duration, and the free intervals.

It is tempting to regard the headache of Type 1 as being the expression of increased intracranial pressure and the resulting irritation of the dura mater. Indeed, until very recently this view was generally held. It was known that the cerebrospinal fluid pressure in this type of headache is usually high and that factors increasing intracranial pressure cause exacerbations of the headache. But similar headaches are found with low or normal cerebrospinal fluid pressures. In 15 to 20 per cent. of intracranial tumours the ventricular pressure is not raised. After lumbar puncture a headache clinically similar in all respects to Type 1 not infrequently develops. The experimentally induced headache following histamine injections occurs after the cerebrospinal fluid pressure, transitorily raised following the injection, has returned to normal. Hence it seems likely that both high and low cerebrospinal fluid pressures may bring into play the mechanism responsible for Type 1 headache.

The most recent work points to the sources of pain being closely related to the intracranial arteries and the dura mater around the large venous sinuses, and that "an abnormal state of tension in the walls of the cerebral blood vessels causes headache." It is, however, useful to pursue Northfield's suggestion further and regard Type 1 headache as corresponding to a visceral pain. On the analogy of cardiac pain I would postulate that the main factor producing Type 1 headache is cerebral anoxia, and that any condition which interferes with adequate oxygen utilization by the brain may result in this type of headache. I have not the space to pursue this conception in greater detail, and I am aware that oxygen deficiency itself may disturb vascular tone, but I would stress the striking benefit which results from oxygen administration in all forms of Type 1 headache (especially migraine and hypertension) and often in meningeal headaches—for example, after encephalography.

On this view all headaches of Type 1, whether the cause be general or intracranial, are an expression of a similar mechanism. Hence the description of the quality of this headache *per se* is not of great diagnostic significance. The features which suggest that a Type 1 headache might be associated with intracranial disease are: (1) its *site* (especially predominantly hemicranial); (2) its *course* (especially if progressively intense); and (3) accompanying signs of (*a*) *increased cerebrospinal fluid pressure* (papilloedema and manometry), (*b*) *focal nerve signs*—irritative and paralytic, or (*c*) *Type 2 headache.*

To summarize: (1) Type 2 headache invariably points to an intracranial lesion associated with meningeal irritation by blood, inflammatory exudate, neoplastic cells, parasites, cyst fluid (for example, hydatid), or direct pressure. (2) Type 1 headache might be due to any general or intracranial lesion which leads to cerebral anoxia. An intracranial origin is suggested not by the description of the headache but by the associated symptoms and signs.

A few words must be added on migraine, epilepsy, and post-traumatic headaches. The focal aurae of migraine which precede the hemicrania by a variable though short period may be accompanied by phenomena of angiospasm and relieved by alleged vasodilators (for example, ergotamine tartrate); but for the headache which follows, if the attack is not aborted in an early stage, these drugs are of no value, though the inhalation of oxygen (100 per cent.) will in most cases give complete relief. Similar beneficial effects have been observed after giving oxygen in post-epileptic headaches. The headache following trauma often has a Type 2 component, though Type 1 is dominant. The relief from post-traumatic headache which occasionally follows air injection into the subarachnoid spaces may be the direct result not only of the breaking down of meningeal adhesions but also of preventing traction on the smaller cerebral arteries by these adhesions, with resulting alterations in vascular tone.

A Scheme for Investigation of Patients

On the basis of the above observations it is possible to formulate a scheme for the investigation of the patient in whom headache is a dominant and early symptom. It must aim at providing answers to three questions: (1) Is an intracranial lesion present? If so, (2) what is its site? and (3) what is its nature?

In the first instance a careful *anamnesis* is essential, for in most cases it will provide the major evidence on which the presence of an intracranial lesion is suspected. We must inquire closely into how long headaches have been present and how often they recur. What is their site, duration, intensity, and character? Are they improving or becoming worse? Is there an aura? Does a late meal, fatigue, worry, or excitement precipitate an attack? Are they related to the menses? Is there a family history of similar headaches, of hay-fever, asthma, eczema, or urticaria? Does heat relieve and cold aggravate? Is the scalp tender to touch? (If so, a "rheumatic" cause is likely.) Does reading bring on the headache? Have glasses relieved them? Is the nose stuffy before the attack? Has there been a recent cold? Is there a nasal discharge? These and a host of other questions may be put, and a correct interpretation and assessment of the answers will almost invariably guide the physician to the seat of the trouble.

Next a careful *clinical examination* should be carried out. It must in all cases include an examination of the fundi for papilloedema, retinitis, arteriosclerosis, choroiditis, etc., and a detailed examination of the central nervous system for evidence of focal disease, increased intracranial pressure, meningeal irritation, etc. Palpation and auscultation of the skull must never be omitted. If necessary, the assistance of an ophthalmologist to exclude local ocular causes—for example, errors of refraction, impaired ocular muscle balance, glaucoma, etc.—and of a throat specialist to exclude causes in the nasopharynx, sinuses, and ears must be sought, though the unmasking of unsuspected pathology in these sites does not necessarily reveal the cause of the headache. In my experience careful questioning will usually decide whether a headache has an ocular or a sinus origin: the characteristics of these headaches do not resemble those we have described as occurring in intracranial lesions. The occurrence of meningitis and cerebral abscess as a complication of sinus disease and otitis must be remembered. Physical examination will include also a search for cardiovascular sclerosis, hypertension, toxaemias, etc.

Accessory Methods of Investigation

If the suspicion of an intracranial lesion is raised, accessory methods of investigation might have to be undertaken. Of these, two are of prime importance: first, an examination of the *cerebrospinal fluid*; secondly, *radiological investigation.* If a tumour is suspected, lumbar puncture must not be lightly undertaken, because of the danger of foraminal or tentorial crowding. In all cases the cerebrospinal fluid pressure should be measured; and a full chemical and bacteriological examination will usually show characteristic changes where meningeal irritation or infection is present. Syphilis, subarachnoid haemorrhage, uraemia, lead encephalopathies, etc., often produce pathognomonic changes in the fluid. *X*-ray examination of the skull and sinuses has become a routine in the investigation of chronic headache. Contrast radiography (after the injection of air into the subarachnoid space or ventricles, or, when aneurysms are suspected, after the injection of thorotrast into the cerebral arteries through the common carotid) is a measure of growing importance, but should be undertaken only by the expert.

In coming to a decision about the *nature of the intracranial lesion* responsible for headache the physician will consider the age of the patient; the site of the lesion; the duration and mode of evolution of the symptoms; evidence of disease elsewhere—for example, syphilis, scar of radical mastectomy, neurofibromatosis, etc.—all of which lesions might have accompanying intracranial pathology; and accessory tests—serological, cutaneous, blood and cerebrospinal fluid examinations, auscultation of the skull, and radiography. A detailed consideration of the significance of these is beyond the scope of my contribution.

Conclusion

I have attempted to formulate the principles which should govern the diagnosis of the intracranial causes of headache, with special emphasis on that aspect of the problem which confronts the general physician. The commoner pitfalls should be avoided by remembering

1. That headaches which are progressively severe or recur in paroxysms of increasing frequency and severity, and are accompanied by dizziness, vomiting, mental deterioration, epileptiform attacks, or focal nerve signs, must be regarded as due to organic brain disease until the contrary is proved.

2. That the onset of migraine after the age of 40 should arouse the suspicion of gross intracranial disease. The most commonly associated lesions are cerebral tumour, syphilis, and hypertensive cerebral arteriosclerosis.

3. That migraine constantly localized to the same side and followed by ocular paresis is almost diagnostic of a basal intracranial aneurysm.

4. That recurring attacks of so-called cyclical vomiting in children, if accompanied by a severe headache, usually indicate a posterior fossa tumour.

5. That the diagnosis of a "psychogenic headache" is often the refuge of the diagnostically destitute. It should be the last and not the first suspicion, and the diagnosis must be based on positive evidence, not solely on "the absence of any evidence of organic disease."

6. That an intracranial lesion, even a tumour, may run its course without at any time giving rise to a complaint of headache.

Summary

The customary classification of the causes of head pains is given.

The following questions are considered: (1) How often does headache indicate organic nervous disease? (2) Of what intracranial lesions is headache a common presenting symptom? (3) What varieties of headache may be found associated with intracranial lesions?

From an analysis of the clinical histories two types which finally emerge are reviewed.

Migraine, epileptic, and post-traumatic headaches are discussed.

A scheme is formulated for investigation of the patient in whom headache is a dominant and early symptom.

Small-pox Vaccination.—The intradermal injection of vaccinia virus which has been cultivated in a medium containing chick embryo tissue produces no untoward reaction and a considerable though possibly not fully adequate degree of immunity. It is suggested that this proceeding should be applied six to twelve months before ordinary dermal vaccination with calf-lymph virus in order to minimize the undesirable effects which the latter may cause. The authors resent the attitude which regards an extensive vaccination scar as a "badge of health"; such a scar is not only unnecessary but gives a sense of security which with the lapse of time ceases to be justified.—Amount and Duration of Immunity induced by Intradermal Inoculation of Cultured Vaccine Virus. T. M. Rivers, S. M. Ward, and R. D. Baird.—*J. exp. Med.*, June, 1939, 69, 857.

HEADACHE AS AN EARLY SYMPTOM OF NERVOUS AND MENTAL DISORDER*

BY

DESMOND CURRAN, M.B., F.R.C.P., D.P.M.

Psychiatrist and Lecturer on Psychological Medicine to St. George's Hospital; Honorary Psychiatrist to the Maida Vale Hospital for Nervous Diseases, London

The frequency of headache as a complaint needs no emphasis, and there is an increasing recognition that it should very often be regarded as evidence of a psychiatric problem. Thus Spriggs (1935), in an analysis of 500 cases, came to the conclusion that in 203 the headache was of "functional" origin. This finding is all the more striking in that Ruthin Castle is primarily concerned with cases of organic disease. There can therefore be little doubt that the headache in a large number of these cases was thought before admission to be directly dependent upon some physical or exogenous cause, which the most thorough physical investigation failed to reveal. Indeed, it is probable that the recognition of headache as evidence of a psychiatric problem is apt only to be reached by a process of exclusion, for which purpose the maxim that it is necessary to eliminate all possible physical causes before deciding that a case is "functional" is taken as the guiding principle. There can be little doubt that a mistakenly conscientious and sometimes ruthless application of this principle can have the most unfortunate consequences; and we have all seen patients who have been subjected to elaborate investigations, treatments, and even operations which, quite apart from the consumption of time and money involved, have been as unnecessary as they have been negative, or even actively harmful, in their results.

The objection may well be raised that it is very easy to be wise after the event, and that the above criticism would be more helpful if psychiatry had really a positive contribution to make to the diagnosis of a "functional" headache, to supplement the purely negative position that this is a question of excluding all possible physical causes. I propose, therefore, to discuss what seem to be some of the *positive* points in the diagnosis of these headaches as revealed by the study of (1) the nature of the complaint, (2) the past history of the individual concerned, and (3) the other or associated symptoms that may also be found. Before attempting these tasks it may be well to touch, very briefly, upon certain general considerations, starting with some possible misconceptions.

Psychiatric and Psychogenic

It should be clear that when the claim is made that the headache of a particular patient should be regarded as evidence of a psychiatric problem, this does not necessarily imply that the origin of the headache is purely psychogenic. Headache is a symptom that may be encountered in every type of mental disorder, and not even psychiatrists, who believe some queer things, hold the view that all mental disorder is purely psychogenic in origin. There is, in fact, general agreement that mental ill-health (with or without headache as an accompanying symptom) results from the interaction of numerous factors, which can roughly be grouped as mental, physical, and constitutional; and these three factors are always inevitably present and operative, though they vary greatly in their practical importance from case to case.

Bearing the above considerations in mind, it is easy to understand how misleading the classical antithesis between "functional" and "organic" may become; for by "functional" is often understood "psychogenic," and by "organic" is often understood "physical" or "exogenous." Thus it is very easy for the organically minded to make the mistake of attributing a headache to some physical finding which may be coincidental, concomitant, or consecutive rather than causal, or which may only be a contributory factor in the production of that general state of mental ill-health of which the headache is a symptom; whereas for the psychologically minded it is very easy to make the mistake of attributing an organic headache to a psychogenic situation which may also be merely coincidental, and, given sufficient determination, a psychogenic situation of a sort is forthcoming in us all.

The question as to whether a headache should or should not be regarded as evidence of a psychiatric problem does not, I think, depend upon the presence or absence of physical findings, but rather upon whether the headache can be directly attributed to the operation of impersonal physical factors, or whether it is attributable to and evidence of personality problems or disorder of the personality as a whole, in the production of which physical and constitutional as well as psychological factors may well have played a more or less important contributory part.

Special Significance of our Head

It is true that we have a general and objective perception of our head as part of our body, but our head also has for us a significance such as no other part possesses. Our head is not only experienced as a physical whole but is recognized as the seat of many of our most important sense organs, upon whose functional integrity depends our mental as well as our physical orientation to the environment. Although the eyes probably hold the first place for most of us in this connexion, the general principle is particularly well illustrated in the stimulating article by Schilder (1933) upon the rôle of the vestibular apparatus in psychiatry and psychiatric symptomatology.

Our heads, and what they contain, are thus of very special importance to us. Moreover, the central nervous system has no sensory organ of its own, and consequently we have no direct perception of its action. It is therefore easy to understand how it comes about that our head is not only something which is physically experienced but is also something which is psychologically experienced as the place where our ego is localized. Our head accordingly comes to mean for us the most important part of being, our personality; and this psychological meaning and significance finds frequent expression in such common metaphors as "losing" or "keeping" our head.

The special significance attached to the head can also be seen in the alarm caused by a fracture of the skull or a tumour in the brain compared with the lesser reaction produced by similar events in other parts of the body. For anything that may affect the brain or head is experienced subjectively as a very special threat to the ego or personality; and, conversely, a threat to the personality or upset of the sense of well-being, however caused, is often experienced subjectively as a head discomfort or headache. This is surely the reason why it should be that head discomfort or headache is such a frequent symptom of mental ill-health; and this head experience or headache has typically a global quality of a highly unpleasant character that pervades the whole being and personality rather than the quality of an objective perception of definite sensory pain.

---

* Read in opening a discussion in the Section of Neurology and Psychiatry at the Annual Meeting of the British Medical Association, Aberdeen, 1939

1. Nature of the Complaint

These considerations may help to explain why it can almost be said that the characteristic thing about the psychiatric headache is that it is not characteristic, except perhaps of the personality of the sufferer. Thus Wilson (1938), in his interesting study of patients with headache referred for psychotherapy, divided them into three groups—those with a sense of pressure or heaviness, those with a dull ache, and those with a sense of throbbing—and came to the conclusion that the former two varieties tended to occur most frequently in patients with a more passive type of personality, while the latter variety occurred in more active or aggressive types. Wilson also makes the important point that half his patients described their headaches in terms which were not exaggerated, and did not use such colourful phrases as "like a screw driven into my skull," or "every hair of my head like a wire being drawn." This is not really surprising, for not every sufferer from mental ill-health needs to find self-expression in melodramatic language.

THE QUALITY OF THE HEADACHE

I submit, therefore, that the typical characteristic of the psychiatric headache is the subjective experience of the quality of what might be called "closeness," as opposed to "remoteness," to the personality. The so-called functional headache has not so much, typically, the quality of a sensory perception as of an unpleasant experience with a special personal significance; whereas the typical quality of the organic headache is that of a sensory perception, about which the patient is able to assume a more or less detached attitude unless the pain is so intense (as in meningitis) as completely to pervade and overwhelm the whole being. Confirmation of this view of the difference in quality comes from the fact that patients who have suffered or who are suffering from both types of headache can usually distinguish between the two quite readily.

Localization.—I think this quality of "closeness to the personality," or special personal significance, is independent of the generalized or localized character of the headache (and "functional" headaches may be either), although it may help to explain why so many "functional" headaches are of a relatively diffuse kind. A possible explanation of the frequent localization at the base of the forehead between the eyes may be due to the fact that, according to Claparède (1924), this is where many of us localize our ego. It would be interesting to know whether blind people do so too, and, if not, whether blind neurotics are such frequent sufferers from headaches of this type. Again, localization to the front or back of the head may correspond to the vulgar divisions of the head in the popular mind, just as the band round the head may have its origin from our habit of wearing caps or hats. The reason for these localizations may hence correspond in principle to that of the glove and stocking distribution of hysterical anaesthesia, the particular localization in all instances being dependent upon the conceptions of the part held by the individual concerned. In other cases the type of headache seems to be derived from the type of emotional experience, as in the "pressure" headache of those who feel "oppressed."

ATTITUDE TOWARDS THE HEADACHE

This feature is really but another aspect of the quality of "closeness" to the personality or "personal significance" which has already been stressed. Hence the headache comes to be regarded in rather a special proprietary way as *my* headache, on to which, as also on to those who try to treat it, is often projected the same or similar emotions that were aroused by the emotional situation to which it owes its birth. Thus, as we all know, the doctor often finds himself used as a convenient vent for dissatisfaction.

DISTURBANCES OF FUNCTION

The characteristic feature here of the "functional" headache is the *selective* disturbance of function that is shown. Thus the complaint may be so severe as to prevent almost any activity; but sleep and appetite may remain unimpaired, and the capacity to perform unpleasant activities is usually particularly affected. Again, the complaint may be that the pain is so intense that the patient can think of nothing else and alleges total inability to concentrate. Yet objective tests for attention and memory may reveal no impairment; while the same examination of a sufferer from an organic headache who complains similarly will usually disclose definite defects.

THE REACTIVE QUALITY

Another very important point of differentiation comes from a study of the factors that influence the headache, when it will be found that the organic headache is influenced by such physical events as changes in posture; whereas the "functional" headache is typically only much influenced by psychological events, such as the arrival of a wanted or an unwanted visitor, or the prospect of being faced by a pleasant or an unpleasant task. These variations are often very obvious to the friends or relatives, who, not unnaturally, incline to take up the attitude that the neurotic patient is putting it on.

Is the Pain Real?—Although, as I believe, the "functional" headache has not typically the quality of a sensory perception, it is nevertheless an extremely real and unpleasant experience, as I for one know. To question whether this experience is a "real pain" seems to me to be playing with words. And indeed, as Muncie (1932) has pointed out in his fascinating study of those patients who complain of a sudden sensation of snapping or cracking in the brain—what he calls "psycholeptic" attacks—certainly this experience, when vivid enough, appears often to possess a definite sensory quality as a component of what I have stressed as the far more important attribute of intense personal significance.

2. The Past History

It will readily be understood that, since psychiatry deals with the total personality, the investigation of a single symptom, such as headache, can only usefully be undertaken in the light of the total setting in which it is shown. Again, considerable intelligence and rather special powers of introspection and exposition are necessary in order that the qualities that have been put forward as characteristic of the "functional" headache can be elicited, and many of our patients are not conspicuous for these gifts. I cannot but feel that Reilly (1926) was fortunate over his patients, whom he was apparently wont to ask, "Is it a real pain or hurt?" to which the "functional" patients replied "No," instead of "Eh, what's that?" or getting angry, as might have been expected. It is therefore essential to inquire carefully into the past history of each patient, and to obtain, wherever possible, an independent account from a friend or relation, who should be seen separately. An independent account often gives a very different complexion to what the patient has said.

This is no place to attempt a brief guide to the taking of a psychiatric history, but the following suggestions are put forward as very rough working rules.

Patients with Good Work Records and Personalities.—In such patients there is a prima facie case that the headache is of organic origin unless a history of special strain immediately preceding the onset of the headache is rather readily forthcoming. The main exceptions here are provided by those who are suffering from a mental illness (with associated headache) which is of constitutional origin, such as an endogenous depression; but in such cases other symptoms of the mental illness in question will also be shown. It is, I am sure, a great mistake to suppose that the sources of strain resulting in a "functional" headache are necessarily of a remote or complex kind, or in any true sense "unconscious." It must, however, be remembered that many patients will at first deny having been worried. They often feel that they should not have been worried, and therefore mistakenly say to themselves and to others that they have not. But a little questioning may readily reveal what has happened—namely, that the patient has been well enough aware of the sources of strain, but has failed to admit them to himself or to connect them with his headache, which is thus substituted for the original source of worry, only to become an additional source of worry in itself. I believe that a large number of anxiety states with associated headache clear up quite simply when the true sequence of events is made clear.

Patients with Poor Work Records and Personalities.—There is a very considerable chance that a headache is of "functional" origin in such patients, even if only a relatively trivial source of worry is forthcoming, or even if no obvious source of worry or strain is forthcoming at all after the most careful inquiry.

3. Associated Symptoms

It is not, I think, sufficiently realized that in the diagnosis of a psychiatric condition as much, if not more, can be learned from the type of reaction that is shown as from a study of those psychopathological factors that may have helped in its production; for, as I have already said, psychiatry is not solely a problem of psychogenesis. It is, of course, obvious that it will only be possible to deal in the most cursory manner with those associated symptoms that should suggest that a headache is part of a psychiatric syndrome.

Schizophrenia.—As Brown (1936) has pointed out in his valuable study of the "bodily complaint," or hypochondriasis, the headache or head complaint of schizophrenia can be of two types: that associated with anxiety or tension and of the non-specific "functional" type that has been described, and that distinguished by its characteristic bizarre and "symbolic" features. Thus a schizophrenic patient said to me recently that he felt not "as if" one side of his head was smaller than the other, but that one side of his head *was* smaller than the other, which he attributed to having his will power drained away by mystical forces. The description of the symptoms to be looked for in the early diagnosis of schizophrenia is an extraordinarily difficult task, but one which fortunately I need not attempt, as it has recently been so admirably performed in the readily available paper of Mayer-Gross (1938).

Organic Reactions.—It is surprising with what frequency the diagnosis of an early organic type of mental reaction, due to arteriosclerosis or other causes, is missed when the symptoms of anxiety or depression accompanying such reactions are so prominent as apparently to dominate the picture (Curran and Slater, 1935). Such patients are often thought to be suffering from a "functional" reaction in the production of which the emotional lability consequent upon organic changes frequently leads to the appearance of what is in fact a spurious psychogenesis, which further confirms this impression. Tests for memory, retention, and concentration will, of course, readily reveal the true state of affairs.

Affective Reactions.—A special difficulty arises in *depressive states,* because such patients often look physically ill, and show in addition the biological concomitants of depression, such as loss of weight, sleep, and appetite. The depressed mood may be thought to be due to the presumptive or assumed physical cause of the headache of which these patients so often complain, which hence may well become the centre of interest. Here again it is impossible to give a brief summary of the symptoms of depression, but reference may be made to the full and excellent description by Lewis (1934). A particular manifestation of affective reactions—namely, depersonalization—is, I think, another frequent stumbling-block, for such patients often complain primarily of their heads, and may not complain primarily or at all of their low spirits.

Anxiety states will, of course, often show some of the other and protean manifestations of anxiety, which cannot be gone into here, but which so often suggest the presence of physical ill-health and may thus lead to the same mistake as was mentioned in the case of depressive reactions.

The *hysterical* or purposive headache is often seen unaccompanied by other symptoms, and the main help must hence often come from points which have already been mentioned, such as the service of such headache in avoiding the fulfilment of unpleasant duties and tasks.

Some of these headaches are, however, very continuous and persistent, and particularly resistant to any form of treatment. It is interesting to speculate as to whether the intractable nature of a "functional" headache of this type as the sole complaint may not be associated with its location in the head, this being perhaps an indication of very deeply seated problems of the personality.

Physiological Component in the Production of "Functional" Headaches

The suggestion has been made more than once that "functional" headaches may, in part at least, be dependent upon the results of the physiological changes accompanying emotional disturbance, perhaps effected through the mediation of the vasomotor system. One does not, of course, doubt that structural or organic changes underlie or accompany all manifestations of function; but for myself I feel very dubious as to whether "functional" headaches are accompanied by, or have partly their origin in, physiological changes that will readily lend themselves to investigation. Thus I doubt whether these "functional" headaches are really analogous, in the mechanism of their production, to migraine, which I would regard as unquestionably a headache of organic type.

The studies of Wolff (1937) and others have, of course, demonstrated the importance of the psychobiological background and psychological factors in the production of many migrainous attacks. But these psychological factors appear to act as a trigger which fires off a train of organic events; and for various reasons I very much doubt if the same underlying sequence can be postulated for the types of headache I have been considering here. I should much appreciate the views of others on this speculation.

Finally, I am very conscious of deficiencies, distortions, and omissions, and of the fact that this paper is full of the dogmatism and economy of truth which is perhaps inseparable from a brief presentation of such a colossal subject.

Summary

The recognition of headache as evidence of a psychiatric problem is discussed.

Positive points in the diagnosis of such headaches are put forward as a supplement to the principle of exclusion, so apt to be used alone.

RESULTS WITH EPANUTIN IN MENTAL HOSPITAL PATIENTS

BY

SUSANNAH DAVIDSON, M.B., B.S., D.P.M.

AND

JOHN D. SUTHERLAND, B.Sc., Ph.D., M.B.

Assistant Physician, Glasgow Royal Mental Hospital

We have recently treated twelve epileptic patients in the Glasgow Royal Mental Hospital with epanutin (sodium diphenyl hydantoinate) in place of either sodium phenobarbitone or prominal. The drug was administered according to the advice of the makers (Parke, Davis and Co.) by gradual replacement of the drug already in use, and the changes in the frequency of fits or in the mental state were studied. The following notes give the results.

Case Reports

Case 1.—A man aged 30, whose first fit occurred eight years previously, has been three years in hospital. He is well preserved intellectually, with several characteristics of the epileptic personality, especially irritability and egocentricity. Major and minor attacks occur with about equal frequency. As he has ground parole and there is amnesia for the fits it is impossible to keep accurate account of the incidence. Before epanutin was given he was receiving in alternate periods of about six weeks either 1 grain of sodium phenobarbitone or 3 grains of prominal twice daily. These changes were usually followed by a considerable reduction in the number of fits for about two weeks and an associated improvement in his mood. Epanutin, one capsule (0.1 gramme) thrice daily, was given for sixty-four days. During the first month there was a striking diminution in the fits, and he was bright and enthusiastic about the new treatment. In the following five weeks, however, he had more fits than usual, twenty being recorded. He relapsed into his former state and requested that the drug be changed; no toxic effects occurred. On resuming prominal he had only seven recorded fits in the next twenty-five days.

Case 2.—A man aged 31 had his first fit when six years old, and he has been ten years in hospital. He is a deteriorated childish personality, with minor fits almost as frequent as major fits. Usually he is maintained on 3 grains of prominal twice daily. Epanutin, one capsule thrice daily, was given for thirty-six days, and was stopped because of increased irritability and difficult behaviour, though no other toxic symptoms were observed. There was a slight increase in the number of major fits and a diminution in minor attacks.

Case 3.—A man aged 46, whose fits began twenty years ago, has been thirteen years in hospitals. His personality is very deteriorated and his behaviour noisy, aggressive, and impulsive. Before the change to epanutin he was given 3 grains of prominal twice daily. On one capsule of epanutin three times a day the fits were less frequent, but the drug was stopped because of nausea and increased irritability.

Case 4.—A man aged 40, with fits during the past twenty years following a war injury, since when he has been in hospitals, has minor fits at long intervals and an occasional major fit. His personality is deteriorated, and occasionally he has attacks of vomiting with headache, though no signs of raised intracranial pressure are present. Epanutin, one capsule thrice daily, was stopped after thirty-six days when one of his vomiting attacks became unusually severe and prolonged. The vomiting disappeared shortly after the withdrawal of the drug; it is probable that the drug was causing an exacerbation of the usual attack. No change was observed in his mental condition, nor was there any significant change in the number of fits.

Case 5.—A man aged 40 whose fits started at the age of 10, has spent the last twenty-six years in hospitals. His mental condition is very deteriorated, his speech being incoherent. The fits are all major ones, and he is usually given prominal. Epanutin, one capsule thrice daily, had to be stopped after thirty-four days on account of nausea and refusal of food. There was no change in his mental condition, and his fits were more frequent.

Case 6.—A man aged 48, whose first fit occurred when he was 22 years old, has been in hospital five years, during which time he has shown progressive deterioration, with considerable memory defect, some confusion, and occasional outbursts of irritability. He has major fits, mainly during the night, at long intervals while on prominal. Each major fit is followed by about twenty-four hours of marked confusion. Epanutin, one capsule thrice daily, had to be stopped after nineteen days because of increased confusion and ataxia, which made it difficult for him to find his way about the ward and which prevented him from being able to feed himself. He was also much more dull and unresponsive than usual. The toxic manifestations disappeared a few days after withdrawal of the drug.

Case 7.—A man aged 55, whose fits began when he was 14 years old, has been thirty-four years in hospital. He is an extremely egocentric childish personality, vain and with numerous mannerisms, who has slightly more minor than major fits. Epanutin, one capsule thrice daily, was stopped on the thirty-seventh day of its administration when he developed an erythematous rash on his hands and legs which gradually spread over his body and which was accompanied by intense itching. Later, oedema appeared and was succeeded by an exfoliative dermatitis. There was no change in his mental condition, but the fits ceased during the epanutin period. The toxic manifestations were relieved by intravenous sodium thiosulphate.

Case 8.—A woman aged 51, with onset of fits in childhood, has been nineteen years in hospital and is now a somewhat deteriorated person with great irritability. Her attacks are usually major with occasional minor fits. Epanutin, one capsule twice daily, was given for fifteen days, when she refused the drug because of headache and nausea. There was an increased irritability, but there was no change in the incidence of the fits.

Case 9.—A woman aged 47, with a history of fits since infancy, has been twenty-eight years in hospital. She is fairly well preserved mentally, with marked religiosity and spells of irritability. Major and minor fits are about equal in frequency, and she is usually given 1 grain of sodium phenobarbitone twice a day. Epanutin, one capsule twice daily, was maintained for sixty-seven days without any change in her mental state or in the frequency of the fits being noted. The drug was stopped when a vesicular rash appeared over the upper half of the right side of the trunk and spread down the right arm.

Case 10.—A woman aged 32 has had fits since the age of 9 years. She has been in hospital for four years and is a very demented personality. Major and minor fits are about equal in frequency. Epanutin, one capsule twice daily, has been given for sixty-eight days with no change in her mental status, but a diminution in the number of fits. No toxic effects developed.

Case 11.—A woman aged 53 has had fits for the past thirty-eight years, twenty years of which have been spent in hospitals. She is a depressed and rather demented bedridden woman whose fits, usually major, are infrequent. On the seventeenth day after epanutin, one capsule twice daily, was begun she asked to have the drug stopped because of headache, dizziness, and general malaise. It was noticed at the same time that a blotchy erythema had appeared on her legs.

Case 12.—A woman aged 49, whose fits began at the age of 13 years, has been in hospital three years and is now a noisy, excitable, and deteriorated personality. She was formerly given 1 grain of sodium phenobarbitone twice a day. As she became noisy at night after epanutin was substituted, she was given 1 grain of sodium phenobarbitone at nights in addition to one capsule of epanutin twice daily. There has been no change in her mental condition or in her fits after seventy-eight days of the epanutin, and no toxic effects developed.

Conclusions

Before drawing any conclusions it must be pointed out that these patients are a rather selected group. Most of them are over 40 years of age and have had a long history of hospitalization and a correspondingly long treatment with drugs. They were almost all admitted for psychotic behaviour as well as fits, and most of them were unsuitable for epileptic colonies, as they were unable to work.

The outstanding result of the treatment is the appearance of toxic effects, eight of the twelve cases showing these within a few weeks. They included headache, giddiness, nausea, loss of appetite, and ataxia. Three cases developed rashes, severe in two, with one being followed by an exfoliative dermatitis. These effects have already been referred to in connexion with this preparation (see references), but their frequent and early appearance obviously restrict the use of the drug, for though some are possibly not serious in themselves they antagonized these patients. One point perhaps worthy of note is that the three youngest patients showed no toxic effects.

In considering the mental effects we had only one patient who showed improvement, but this lasted for only a few weeks, after which he resumed his former state. It has also to be recalled that this patient showed a temporary improvement upon a change from sodium phenobarbitone to prominal or vice versa. The effect of the change to epanutin was rather more marked, however. His relapse followed upon the recurrence of fits, but the appearance of toxic effects in other cases made us reluctant to increase the dose. It would appear that in his case, as in some of the others, epanutin makes a useful addition to the drugs on which patients may be maintained for a few weeks. The absence of sedative effect proved an undesirable feature with several of our patients, as it released the excessive irritability and, in some cases, impulsive behaviour which was much relieved by the other drugs.

With regard to the anti-convulsant properties, the data are too limited to make critical observations. The table shows the number of fits to be expected during the period that epanutin was given, this being calculated from the average incidence of fits in the preceding six months in each case. As there appeared to be little change in the character of fits in most cases we have combined the major and minor attacks in the term "fit." It will be seen that there is a balance in favour of epanutin.

Table showing Summary of Results

Case No.	Age in Years	Duration of Epilepsy in Years	Change in Mental State during Epanutin Period	Period of Epanutin Administration in Days	No. of Fits in Epanutin Period	No. of Fits expected on Former Drugs	Reasons for stopping Drug
1	30	8	Brighter for 4 weeks	64	Not recorded		More fits than usual
2	31	25	Increased irritability	36	4	5	Increased irritability
3	46	20	,, ,,	34	2	4	,, ,, and nausea
4	40	20	No change	36	3	2	Vomiting
5	40	30	,,	34	13	10	Nausea ; refused food
6	48	26	Dull and unresponsive ; increased confusion	19	1	2	Confusion and ataxia
7	55	41	No change	37	0	4	Severe rash followed by exfoliative dermatitis
8	51	45	More irritable	15	3	2.5	Headache and nausea ; refused drug
9	47	46	No change	67	7	8	Vesicular rash
10	32	23	,,	68	3	5.5	Not stopped
11	53	38	,,	17	—	—	Rash, headache, and giddiness
12	49	36	,,	78	11	12	Not stopped

In short, our experience suggests that the drug is of use in the younger and better-preserved patients, but on account of its toxic effects it is advisable not to maintain it for more than a few weeks at a time.

We are indebted to Dr. Angus MacNiven, physician-superintendent of the Glasgow Royal Mental Hospital, for permission to give the treatment and to publish the results. We have also to express to Messrs. Parke, Davis and Co. our thanks for a trial supply of the drug and for advice.

Muscular Dystrophy and Hypothyroidism.—In the issue of *Revue Neurologique* for May, 1939 (p. 513), P. Mollaret and J. Sigwald contribute a paper on "Generalized Muscular Atrophy of Rapid Onset in an Adult associated with Latent Myxoedema clinically cured by Thyroid Medication." In the same number (p. 548) G. Bourguignon also deals with the improvement effected by thyroid treatment of the condition. A case of generalized muscular hypertrophy without weakness or myotonia is described in a man of 56. The basal metabolic rate was − 13 per cent., and there were clinical signs of hypothyroidism. Biopsy showed no definite muscular abnormality. These symptoms, and also alterations in electrical excitability of the muscles, disappeared with thyroid medication. The literature on this condition is reviewed. The muscular changes are thought to be directly related to the hypothyroidism.

TREATMENT OF IRREDUCIBLE INTUSSUSCEPTION DUE TO MECKEL'S DIVERTICULUM

BY

R. STUPPEL, F.R.C.S.Ed.

Resident Surgeon, Montagu Hospital, Mexborough

Intussusception occurring in adolescence as a result of an invaginated Meckel's diverticulum appears to be not uncommon. Hamilton Bailey (1938) says that it is so regularly the cause that a precise pre-operative diagnosis can be made. Harkins (1933), on the other hand, from a statistical study of the literature, concluded that a Meckel's diverticulum accounts for only a small proportion of intussusceptions, while Ladd and Gross (1934), at the Children's Hospital, Boston, found that fourteen out of 372 cases were due to an inverted Meckel's diverticulum. Harkins (1933) found that the great preponderance of cases occur in the first ten years of life, but Romanis and Mitchiner (1937) believe that enteric intussusception is usually seen in children between the ages of 3 and 10; that it is the second commonest variety; and that it is usually due to a Meckel's diverticulum or an intestinal polyp. No age, however, is exempt, and Nédelec (1937) describes a case in a woman aged 52.

Perrin and Lindsay (1921–2) in their analysis of a large series of cases of all types of intussusception found that the enteric variety has much the highest mortality. This type tends to be recurrent or subacute, and in consequence does not reach the surgeon until late. In addition, no difference exists in the calibre of the entering and ensheathing layers, such as is found in the ileo-colic variety. The combination of these two factors renders the enteric intussusception frequently irreducible.

The problem that confronts the surgeon when he opens the abdomen and finds himself face to face with an irreducible intussusception is one which has exercised the minds and ingenuity of many. Where the intussusception is irreducible but not gangrenous Rowlands and Turner (1937) advise restoring the continuity of the canal by a short-circuit anastomosis, and leaving the mass in the abdomen; and they add—referring to infants—that recovery after resection of a gangrenous intussusception is a very rare event. Romanis and Mitchiner (1937), however, say that performance of a short circuit above and below the intussusception, while relieving the obstruction, still leaves the possibility of gangrene occurring with peritonitis. This latter teaching is supported by the figures given by Perrin and Lindsay (1921–2), in whose series the only treatment that was attended by any success was excision with end-to-end or lateral anastomosis. And Clubbe (1921) makes a plea for more frequent excision.

Elliot-Smith (1935) reports three very interesting cases of irreducible intussusception, in which he did a lateral anastomosis and returned the tumour to the abdomen, with or without suturing the neck. All three patients recovered. He says that peritonitis, even in fatal cases untreated by operation, is rare, as the gangrene is limited to the intussusceptum, and the ensheathing layer is usually healthy. Illingworth and Dick (1938) also consider that the vitality of the sheath is seldom imperilled.

The case that is now reported is instructive because it illustrates the danger of leaving behind in the abdomen an irreducible intussusception, which may at any moment become gangrenous and prove fatal.

Case Report

A girl aged 9 was admitted to hospital as a case of acute appendicitis. There was a history of previous attacks of abdominal pain in the right lower abdomen since she was 6 years of age, occurring at intervals of about six months, each time more severe, and lasting for about two hours or longer. There had never been any vomiting until this last attack, which had begun on the evening of the day before admission. There had been no constipation up to the onset of the pain, but she had not had her bowels open since then, nor had she passed any blood or mucus per rectum. She had never been seen by a doctor during her previous attacks, which had always subsided spontaneously and left her quite well.

On examination she was a well-nourished sturdy child, but somewhat pale. The pulse rate was 116, the temperature 99. While she was being examined she was obviously having spasms of colic, and cried out with the pain. The abdomen was slightly distended, but not rigid. There was a mobile horseshoe-shaped tumour, lying more or less equally on either side of the umbilicus.

Operation.—Under gas-oxygen-ether, the abdomen was opened by a midline subumbilical incision. The intussusception presented at once, and was readily delivered into the wound. It consisted of the terminal portion of the ileum, which had become bent until it occupied three-quarters of a circle, and measured about ten inches in length. The ends of the limbs were quite close together, and extended down to the base of the mesentery. It was quite irreducible. The sheath was healthy and showed no visible signs of gangrene. A lateral anastomosis was performed between the entering and the ensheathing layers an inch or so beyond the extremities of the loop, and the mass was returned to the abdomen. Two days later the pulse and temperature were rising, and the child was having pain. The abdomen was reopened through the original incision. There were patches of gangrene on the sheath of the intussusception. It was withdrawn from the abdomen, and, in manipulating it, the gangrenous areas gave way and spilled foul contents. The whole loop was excised, leaving the anastomosis intact, and the ends were crushed and invaginated.

During the next few days the child passed first a little blood per rectum, and subsequently loose stools. Her condition improved, and, apart from a slight infection of the anterior abdominal wall, she made an uneventful recovery.

DESCRIPTION OF SPECIMEN

The portion of bowel resected was the last twenty inches or so of the ileum. That portion of the bowel which formed the sheath was gangrenous. Within the inner layer, and forming the apex of the intussusception, was a completely invaginated Meckel's diverticulum. It was three inches long, and at first sight was mistaken for an intestinal polyp. In structure it resembled normal small intestine, and was everted without difficulty.

Discussion

This case very clearly proves the danger of leaving behind an intussusception, even though at the time the ensheathing layer appears to be healthy. Such a course may apparently be taken on occasions with impunity, but it seems quite an unjustifiable risk. The extra time needed to excise the tumour and invaginate the ends after the anastomosis has been completed is so small that it cannot materially add to the shock of the operation. If an excision is undertaken it is technically easier and quicker to perform the (lateral) anastomosis before amputating the tumour, just as, in a partial gastrectomy, it is easier to anastomose the stomach to the jejunum before amputating the stomach.

THE DIAGNOSIS AND TREATMENT OF INFANTILE MASTOIDITIS

BY

P. W. LEATHART, B.A., M.B., B.Ch.

Surgeon in Charge of Throat and Ear Department, Royal Liverpool Children's Hospital

In winter a children's hospital contains many cases of severe air-borne infection—influenza, bronchitis, pneumonia, etc. In summer food-borne infection—diarrhoea and vomiting—is more commonly seen. In both summer and winter many bottle-fed infants are admitted. With suitable treatment and feeding a majority of these cases recover without complication. Some patients, however, perhaps after a temporary improvement, begin to go downhill mysteriously; lose weight rapidly, and die. In such cases, although during life the physical signs usually associated with mastoiditis, such as discharge from the ear and swelling behind it, were absent, yet a post-mortem examination has frequently revealed the presence of a purulent mastoiditis on one or both sides. Thus investigation of the records of 146 recent consecutive necropsies revealed that mastoiditis undiagnosed in life had been present on one or both sides in no fewer than twenty-nine cases. It is clear, therefore, that unsuspected mastoiditis is a common and often fatal complication, developing insidiously during the course of the above diseases.

The frequency with which mastoiditis complicates the above diseases has not been sufficiently realized: the reason for its development is to a certain extent shrouded in mystery, and since the physical signs which point to its presence are often masked by those of the disease from which the child is suffering, some confusion exists with regard to the diagnosis.

In order to clarify the problem it is proposed to discuss it under the following headings, pointing out: (1) the extreme frequency of mastoiditis as a complication in the above diseases; (2) the method by which infection gains access to the mastoid antrum and the material which causes it in each disease; (3) the local and general physical signs by means of which diagnosis can be made with confidence; (4) the treatment which experience has shown to be effective; (5) certain nursing details which have been found useful in prevention and helpful in promoting spontaneous recovery.

Frequency

At the Royal Liverpool Children's Hospital during the last six months mastoiditis has been recognized as a complication in thirty-six cases of children suffering from one or other of the above diseases. All were referred to the laryngologist by the courtesy of the physician or surgeon in charge, and in nearly all of them the classical physical signs usually associated with mastoiditis were absent.

Method of Infection

We must remember that the Eustachian tube is more horizontal in children than in adults, and that normally it opens with each act of deglutition. On account of this horizontal position any material in the post-nasal space finds its way through the Eustachian tube into the tympanum and thence to the mastoid antrum more easily than in adults—especially when the child is lying on his back while feeding. It is thus seen how easily infected mucus can enter the tympanum from the post-nasal space in air-borne disease, and how vomited material may do so in food-borne disease and milk in bottle-fed infants.

Diagnosis

We have seen that diagnosis is often obscured not only by the physical signs of the disease from which the child is suffering but also by the fact that those usually associated with mastoiditis are absent—for example, as a rule there is no discharge from the ear, and swelling behind it is never present at a stage when, in the interest of the child's life, treatment is imperative. Moreover, the child is too young to tell us that he has earache, and palpation over the mastoid process gives us no definite help. Nevertheless experience has shown that mastoiditis can be recognized in these children at an early stage by the presence of local physical signs, other than those usually associated with mastoiditis, in conjunction with considerations in regard to the child's general condition.

GENERAL CONSIDERATIONS

In the first place the child is suffering from an air-borne or food-borne infection or is a wasted bottle-fed infant. We have seen that in these illnesses mastoiditis is a common complication. If, therefore, such a child is not improving, mastoiditis is likely to be the cause and should always be suspected. Further, it may be that for the last two or three days an increase in the temperature has been noted. Perhaps the child has been crying out as if in pain. The nurse may have noticed that he has been putting his hand to his head or pulling at his ear or rolling his head on his pillow. Diarrhoea and vomiting may have increased or, if not present, have now appeared, leading to rapid loss of weight and dehydration.

LOCAL PHYSICAL SIGNS

A discharge from the ear is seldom present, but examination with the electric auriscope may reveal a pool of pus too small to appear outside. Often the tympanic membrane is pink, especially in the upper and posterior quadrant, or it may only show a loss of lustre or a wrinkled appearance like a piece of crushed tissue paper. Frequently nothing abnormal is seen.

There is, however, one physical sign which is constant—one that has not received the attention it deserves. It consists in the presence of a palpable gland or glands in the posterior triangle of the neck behind the sterno-mastoid muscle. The glands in this region are often easily palpable, but sometimes difficulty is experienced in detecting them, for they are small at first, but increase in size with the chronicity of the mastoid infection. It is therefore to be expected that at an early stage the glands are more difficult to find than at a later date. There are, of course, other conditions which produce enlargement of the glands in the posterior triangle of the neck, such as sepsis in the area of skin the lymphatics of which drain into the glands. But of all the conditions causing enlargement, mastoiditis in its catarrhal or purulent stage is by far the commonest. In the event, therefore, of glands being felt in this situation, and having excluded other causes, mastoiditis should always be suspected.

When this suspicion is strengthened by the presence of one or other of the above local signs and by the fact that the child is suffering from any one of the above diseases, experience has shown that a diagnosis of mastoiditis can be made with almost absolute certainty. Having made the diagnosis it is not suggested that an immediate operation is necessary in every case, for it has been found that in some instances mastoiditis in its early stage subsides spontaneously. Immediate operation is necessary only in the case of a child whose general condition is not improving, and who is losing weight and becoming dehydrated. In such a child operation is urgently called for in the interest of his life.

Treatment

About fifteen years ago the appalling mortality among young children in whom the mastoid cells showed unsuspected disease at necropsy led to a determined effort to recognize the condition during life and to adopt treatment at an early stage in the disease in the hope of saving the lives of children who would otherwise die. At first paracentesis was tried in those in whom the tympanic membrane showed changes. This proved unsatisfactory, for although some cases improved for a time, yet most of these patients died, and purulent mastoiditis was found post mortem. Gradually more and more were subjected to mastoidectomy, with the result that many children who were expected to die made a spectacular recovery.

Both now and for several years past the diagnosis is and has been made in the way outlined above, and if the child is losing weight or going downhill an immediate exploration of the mastoid is advised and carried out. The operation is an extremely simple one, and can be completed in less than ten minutes. It consists in opening the mastoid antrum and any cells which may be present, and leaving the lower part of the wound open so that drainage may take place posteriorly. The typical condition found at operation in an early case consists in the presence of swollen polypoid mucous membrane filling the antrum and any cells which may be present. At a later stage the polypoid mucous membrane is seen to be bathed in muco-pus; later still, frank pus is found, with destruction of bone. Experience has shown that, in mastoiditis due to air-borne infection, pus and bone disease are more likely to be found than when it develops as a complication in food-borne infection or in wasted bottle-fed infants.

We have seen that the complication is often bilateral, and as most of the children are critically ill it is not always a safe risk to operate on both sides at the primary sitting. We must therefore decide by the physical signs on which side to operate first. The rule is to choose that side on which the posterior glands are the larger, or that on which the tympanic membrane is the more abnormal—with one exception. In a bilateral case, if one ear is discharging and the other dry it has been found safer to choose the latter ear for the primary operation; for on the discharging side the mastoid cells are draining and on the dry side the infection is pent up.

Nursing Details

We have seen above how readily muco-pus, vomit, or milk can enter and infect the mastoid antrum while the child is lying on his back, and especially while being fed in this position. It is suggested, therefore, that children suffering from air-borne infection, diarrhoea, and vomiting, or, wasted bottle-fed infants, should never be fed while lying down, and that during the intervals of feeding they should be well propped up on pillows and constantly turned from side to side—and never be allowed to lie on their backs for any length of time. The routine adoption of these suggestions at the Royal Liverpool Children's Hospital has not only led to a definite decrease in the frequency of mastoiditis as a complication in the above diseases, but has also proved itself to be a potent factor in promoting spontaneous recovery in those cases as yet not ill enough to require operation.

An analysis of the case sheets of the thirty-six cases mentioned above brings out the following interesting facts.

Enlarged glands in the posterior triangle were present in every case. In seven cases the tympanic membrane appeared normal. In twenty-three cases the tympanic membrane was abnormal or pus was present in the meatus. In six cases there is no note as to the appearance of the tympanic membrane. Seven cases recovered spontaneously. Twenty-nine cases were operated on, either on one or both sides, mastoiditis in the catarrhal or the purulent stage being present in all. Eight of these patients died (27.5 per cent.). Twenty-one recovered (72.5 per cent.).

All the cases subjected to operation were critically ill, some apparently in the last stages of dehydration, which even intravenous salines had failed to improve. When this is realized a recovery rate of 72.5 per cent. must be considered eminently satisfactory, for, unless the complication is recognized and treated, death is almost certain.

Conclusions

That many children considered to have died from one or other of the above diseases do in reality succumb to unrecognized mastoiditis.

That this complication occurs with much greater frequency than is generally realized.

That diagnosis even at an early stage can be made with confidence.

That mastoidectomy will save the lives of about 70 per cent. of the children in whom the complication is present.

That young children should never be nursed or fed lying on their backs.

Summary

The frequency with which mastoiditis complicates other diseases in children is stressed.

The diagnosis and treatment of the condition are detailed.

Nursing precautions which lead to a decrease in the incidence of mastoiditis in child patients are given.

An analysis is made of the case sheets of a series of thirty-six such cases occurring at the Royal Liverpool Children's Hospital.

In *La Presse Médicale* for June 28, 1939 (p. 1031), Desmarest and Capitain discuss the value of testosterone treatment in menorrhagia, metrorrhagia, and menopausal disturbances. They describe a number of cases of metrorrhagia and menorrhagia in young women and in women at the menopause, and also certain cases of post-menopausal disturbances which they have treated with testosterone propionate with excellent results. In uterine haemorrhage they give testosterone alone, while in amenorrhoea they combine it with small doses of folliculin.

Clinical Memoranda

Artificial Restoration of Cardiac Rhythm

The following case, in which restoration of cardiac rhythm was successfully produced by artificial means, presents several features of interest.

CASE RECORD

A man aged 72 was admitted to hospital suffering from obstructive jaundice. Examination revealed an enlarged heart and auricular fibrillation. As, however, the biliary obstruction was complete it was decided that after the intravenous administration of glucose and calcium gluconate an operation should be performed. Spinal anaesthesia, using 1 in 1,500 percaine, was induced, and was supplemented by gas-and-oxygen administered by means of a McKesson apparatus. Shortly after the peritoneal cavity had been opened respiration ceased, and it was found that the heart had stopped. An incision was made in the left cupola of the diaphragm, and a hand was inserted into the pericardium. The heart was "massaged," or, rather, compressed and allowed to relax at regular intervals. Meanwhile, the anaesthetist carried out artificial respiration by means of intermittent compression of the reservoir of the McKesson anaesthetic apparatus. After a few minutes the heart beat spontaneously for about a dozen beats and then ceased. After another interval some further spontaneous contractions took place, again ceasing. Twenty minutes from the moment that the heart first ceased to beat it was felt that no further efforts would be of any use.

A "post-mortem" examination of the bile ducts and duodenum was carried out before closing the abdomen. An assistant then took this opportunity of practising cardiac massage, and twenty-nine minutes from the time that the heart first ceased to beat contractions were again produced; these continued. In a few minutes strong regular beats could be felt at the wrist, and peripheral circulation had been established. The abdomen was closed. Spontaneous respiration had not, however, been re-established, and artificial respiration was continued.

It was thought that prolonged cerebral anoxaemia had produced paralysis of the whole brain, including the respiratory centre in the medulla, and it was hoped that if an adequate circulation of oxygenated blood could be maintained for a sufficiently long time some degree of recovery would take place. Two and a quarter hours after the operation the first spontaneous respiration occurred. This was succeeded in five minutes by a second and then a third. At this time the patient showed complete flaccidity of all voluntary muscles and absence of all reflexes. The respirations were slow, gasping in character, and completely irregular.

Within an hour marked changes had occurred. The patient now presented the typical picture of decerebrate rigidity; the arms were flexed across the chest, with the wrists and fingers flexed; the knees were extended, and the ankles in the position of plantar flexion. The respiratory rhythm was now characteristic of that described by Lumsden as apneustic. The only further change in the patient's condition was that respiration later became more normal in rhythm. The man "died" eighteen hours after operation.

DISCUSSION

The opinion is generally held that restoration of cardiac rhythm can occur up to fifteen minutes after the heart has stopped. In the above case an interval of twenty-nine minutes elapsed. While this may be explained by assuming that cardiac massage itself can maintain some sort of circulation, the case does show that even more prolonged efforts should be made.

The recovery of the centres in the brain stem occurred in accordance with the known fact that the lower and more primitive centres show an increasing resistance to prolonged anoxaemia and, similarly, a more rapid recovery than the higher centres. Lumsden suggests that the respiratory centre can be divided into three sub-centres as follows: in the upper medulla just below the striae acousticae is the gasping centre; just above this is the apneustic centre, which is primarily responsible for the inspiratory movement; and, lastly, in the region of the upper pons is the pneumotaxic centre, which normally checks the activity of the apneustic centre and is responsible for the production of the normal respiratory rhythm. When an animal dies from asphyxia or from any interference with the blood supply to the brain stem these three parts of the respiratory centre suffer in turn in a descending order. Recovery occurs in the reverse order. This process of recovery was exactly demonstrated in our patient.

A similar ascending recovery was shown by that part of the central nervous system which controls muscle tone. At first the patient presented complete muscular flaccidity such as would be produced by transection of the medulla below the lateral vestibular nucleus of Deiters. Later the picture was that of section through the midbrain or pons above Dieters's nucleus and below the middle third of the red nucleus. No recovery of any centres above this level occurred.

I am indebted to the late Mr. J. L. Joyce for permission to publish this case.

Epanutin in Epilepsy

Epanutin (sodium 5:5-diphenyl hydantoinate), although a comparatively new drug, is evoking increasing interest among clinicians treating epilepsy. As yet, however, reports on its clinical trial are of necessity scanty. An account, therefore, of experience with this form of treatment extending over some months may be of interest.

The original claim of Merritt and Putnam (1938) that epanutin is of value in controlling major epileptic seizures seems to be undoubted. That it is the treatment of choice in all or most cases of epilepsy does not appear to be so certain. As with many other drugs exerting a powerful effect on bodily functions, epanutin has considerable toxic action. This, though not necessarily a bar to its use, necessitates care and watchfulness, and it seems unlikely that it will supersede, at present anyway, the more time-honoured treatment with luminal and the bromides for continuous general use. Already a number of toxic effects have been noted, ranging from nausea, vomiting, and epistaxis to various skin rashes, hypertrophy of the gums, and marked ataxic symptoms. This last complication is particularly dangerous, as it tends to come on insidiously after a considerable period, and may easily be thought by the unwary to be due to the epilepsy and therefore be taken as an indication for continuing the drug or even increasing the dose.

In the present series of cases toxic effects have been comparatively few, possibly because the dose used has not been large. Skin rashes of morbilliform type occurred during treatment in two cases. These cleared up on discontinuing the drug. One patient, unfortunately, started to have severe fits as soon as treatment was stopped and died within a week from status epilepticus, in spite of all the recognized forms of treatment. Such an event seems to be an indication for substituting other drugs before omitting epanutin. No cases of pronounced ataxia have occurred, but slight tremor of the hands and face has been observed, and numbness and tingling of the hands and feet have been complained of with some frequency. Transient nausea seems to occur fairly often, and constipation may be troublesome.

The initial dosage in every case was one capsule (0.1 gramme) three times a day, increased later to four capsules a day in a few instances. The number of fits was in most cases greatly reduced, some patients having no fits at all for long periods, but in a few cases little or no effect on the seizures was apparent.

Table showing Monthly Incidence of Fits before and during Treatment with Epanutin

Case	Month prior to Epanutin	Months of Treatment						
		1	2	3	4	5	6	7
A	8	0	3	0	2	4	0	1
B	23	1	1	2	12	0	6	6
C	19	0	0	0	23	5	6	—
D	10	0	0	0	0	0	0	—
E	27	7	0	0	1	0	0	—
F	4	8	7	8	7	18	—	—
G	21	1	0	4	3	2	—	—
H	5	2	3	5	—	—	—	—
I	9	0	0	0	—	—	—	—
J	1	3	4	—	—	—	—	—
K	4	2	0	0	—	—	—	—
L	2	0	2	0	—	—	—	—

In cases B and C the increase in the number of fits in the fourth month was due to a sudden exacerbation in spite of treatment. Cases F, H, and J are examples of failure to respond at all to the drug. In evaluating results it must be remembered that even cases of untreated epilepsy tend to show great variation in the incidence and periodicity of the fits, and that many factors, even, possibly, the change in treatment itself, may have some effect on the number of fits.

In those cases which responded well, however, marked improvement was noted in other spheres. Bodily and mental health were both improved, the latter possibly being associated with the absence of the soporific effect produced by such drugs as luminal and the bromides. This feeling of well-being was pronounced in a considerable number of cases—weight was gained, appetite improved, and zest for occupation increased. All these factors in addition to the diminution in fits are of great benefit to the patient. Therefore the conclusion arrived at is that although epanutin is possibly not the ideal drug in the treatment of epilepsy, it is nevertheless of considerable value in the control of fits and is well worth further trial in selected cases, especially where the treatment can be supervised. Further research along similar lines may well yield an even more suitable substance.

I wish to thank Dr. W. D. Nicol, medical superintendent of Horton Hospital, Epsom, for his kindness and permission to report these cases.

J. J. Laws, M.R.C.S., L.R.C.P., D.P.M.,
Assistant Medical Officer, Horton (L.C.C.) Hospital, Epsom.

Reviews

EVERYDAY TREATMENT

Treatment of Some Common Diseases, Medical and Surgical. By Various Authors. Edited by T. Rowland Hill, M.D., M.R.C.P. (Pp. 398 ; 90 figures, some of which are in colour ; 3 tables ; 15s. net, postage 6d.) Edinburgh: E. and S. Livingstone. 1939.

Dr. T. Rowland Hill has collected a series of contributions by members of the staff of the Southend General Hospital on the methods of treatment of some of the common medical and surgical complaints, and the result is a book which will be valuable to practitioners. The range of subjects chosen is a wide one, and the method of approach is through a short reminder of the pathology of the condition under consideration. The volume is readable, the illustrations good and sufficient, and the book may be recommended as a sound statement of present-day therapeutics. A good start is made with two articles, on the treatment of angina pectoris and of heart failure, by Dr. William Evans, who summarizes his careful observations on the efficacy of various drugs and indicates the occasions for their use. The editor is responsible for two chapters on anaemia and on cerebral vascular disease. In the former he offers a classification which will be useful to practitioners in deciding the nature of the anaemia and so ordering the appropriate treatment. Cerebral vascular disease, in its different varieties common in infancy and in old age, tends to be overlooked in the early stages in the middle-aged when rest and treatment may bring about compensation. Pleurisy and the various types of broncho-pulmonary suppuration from catarrh to bronchiectasis are discussed by Dr. Sleigh Johnson. Dr. J. N. O'Reilly gives a useful sketch of the diagnosis and treatment of the commoner digestive disorders of childhood, preceded by a short but complete summary of the feeding of the normal infant, whether breast or artificial feeding is used.

Dr. L. T. Bond gives a fair summary of the present position of the prophylactic treatment of infective diseases by active immunization. At present there is rather a slump in vaccine therapy since the wave of optimism following the introduction of comparatively non-toxic chemotherapeutical compounds, and, as Dr. Bond points out, there is still a long way to go before it can be said that protection can be afforded against the majority of bacterial and virus diseases. Dr. R. H. Campbell deals with the treatment of haemorrhage from peptic ulcers on the lines advocated by Meulengracht, and points out that the initial nausea may often be overcome by persuading the patient to make a beginning with food, because once some food is retained the peristaltic action of the stomach tends to move on the blood clot and nausea ceases. Supporting intravenous therapy of one kind or another is so important that every medical practitioner should have available the material and apparatus for this immediate and life-saving measure when called to sudden and severe haemorrhages.

Among the surgical subjects the practitioner will find Sir William Wheeler's survey of the present position in regard to the management of enlarged prostate a most useful guide in advising and treating his patients, and Mr. Barlow's on suppurative lesions in the neighbourhood of the knee-joint and on infections of the face and neck, both of which if not dealt with adequately may bring about complications dangerous to life. Mr. Knight deals with head injuries and their complications, and Mr. S. G.

Mayer with post-operative complications of wounds in general. The problems of earache and dental caries as met with in general practice receive attention, and some common skin lesions. There are chapters on the management of delay in labour and of the various causes of abnormal uterine haemorrhage. Dr. G. White Phillips gives a short description of the effects of x rays on dividing cells. The dose must be above a certain minimum and varies for different cells; the approximate cancericidal doses are now known for certain malignant tumours. The methods of application and effects of treatment are discussed. Excision is the method of choice except in epithelioma of the lips and of the anterior third of the tongue. Excision must, of course, include the neighbouring lymphatic system. In inoperable cases radiation is the only form of treatment; the results of treatment by deep x rays in a number of cases with varied conditions are described and illustrated; unfortunately, injury of the skin and deeper tissues may occur; these effects, their treatment, and the sequelae are shortly indicated. Shock during anaesthesia and the means of meeting it and the newer methods of pre-anaesthetic medication are discussed.

In a notable article Mr. Wilfred Trotter makes a plea for earlier diagnosis of malignant disease of the pharynx. Though not common, its earliest symptoms are so mild, its advance so insidious, and its consequences so devastating that the practitioner is urged to take more notice of the complaints of patients with persistent throat symptoms; especially to learn the use of the laryngoscope, by means of which changes in the arytenoids may be seen or excluded; in the event of any suspicion of trouble expert opinion is to be sought. The details of treatment are explained and illustrated, but much will be gained if early diagnosis enables treatment to be instituted at a time which should at least ensure the level of success reaching that of any other cancer.

HEALTH ADMINISTRATION

Health Officers' Manual. General Information regarding the Administrative and Technical Problems of the Health Officer. By J. G. Geiger, M.D., Sc.D., LL.D. (Pp. 148; illustrated; 6s. 6d. net.) London: W. B. Saunders. 1939.

The medical graduate or licentiate, during the courses which he pursues in order to fit himself to hold a position as a medical officer of health, is required in this country to devote his attention to a couple of study groups, in the latter of which is included the study of health administration. This subject usually appeals to him as wide but vague, and, as an onlooker at this stage with no direct responsibility, he is apt to think administration an easy and not very urgent matter, a capacity for which he will develop automatically whenever the need arises. But when the need does arise and he becomes a medical officer, no longer a spectator but an active agent responsible for the health destinies of a community, he is likely enough to make the discovery that administration is not so easy after all, and so to welcome a guiding hand, especially if proffered by one who has competently trod the way before him. Such guidance is usefully made available to medical officers of health in a recently issued work by Dr. J. G. Geiger of San Francisco, who, adopting his own area as the pattern, exhibits the practical organization and interrelations of the manifold components of an important public health department. He believes in effective contacts between the health section and the other activities of the local authority. He thinks it well that the medical officer should be supported by an advisory board, so composed as to represent all significant local interests. He approves, also, of a technical advisory board, including medical men. Publicity is to him an obligation which he owes to the community, and he favours political relations if of a productive kind. Among many other topics aptly presented in the book are mental hygiene, the inspection of restaurants, hospitals, housing, camp sites, and the limitations of laboratory diagnosis.

GYNAECOLOGY AT JOHNS HOPKINS

Collected Papers by Members of the Gynecological Department of the Johns Hopkins Hospital and University, 1929-38. Volumes A and B. The Johns Hopkins Hospital. 1939.

The Johns Hopkins Hospital celebrated its fiftieth anniversary on May 7, 1939. On that day Dr. Thomas S. Cullen, professor of gynaecology, Johns Hopkins University, and visiting gynaecologist, Johns Hopkins Hospital, signed the preface to the two volumes of collected reprints of 122 articles which represent the published work of the department of gynaecology for the years 1929–38 inclusive. The addition of these volumes to the three existing ones makes a complete record of all the work published by the department since 1916.

"A father is proud of his sons and a surgeon may admire his own handiwork. Both are usually guilty of exaggeration," writes Dr. Lawrence Wharton at the beginning of an article in which he describes a new technique for constructing an artificial vagina (reprint 117). No exaggerated pride is revealed, however, by Professor Cullen in the simple preface to these volumes when he writes: "My affectionate regards and sincere thanks go to all members of the gynaecological staff for their admirable co-operation, their unflagging energy, and for what in these volumes they have added to our knowledge of gynaecology and abdominal surgery." The contributions that have been made by this department in the last ten years are very considerable, and for that reason the record made by the collected reprints is a valuable one. Novak, who must be regarded as one of the most eminent living authorities on gynaecological pathology and endocrinology, has contributed numerous papers on these subjects, with special emphasis on the clinical applications of advances in knowledge. His articles, which are always stimulating and a delight to read, have played a tremendous part in informing the profession, both in America and abroad, of progress made. They have also been an encouragement to other workers to continue in the search for truth. The epoch-making work of Hunner on the subject of the urinary tract has done much to draw attention to the important relationship that can exist between genital and urinary lesions, and his articles on ureteral strictures have been of the greatest importance to clinical gynaecology.

Space permits only of mention of other workers, such as Wharton and Richardson, whose contributions have been most valuable. One of the outstanding publications in the series is the article on "Lesions of the Rectus Abdominis Muscle simulating an Acute Intra-abdominal Condition" by Cullen and Brodel (reprint 106). It is certainly the classic in English on this subject, and is a model of how such a paper should be arranged and written. Many in this country will remember with great appreciation the address on "The Training of the Gynaecologist" read by Dr. Cullen to the Section of Obstetrics and Gynaecology at the Annual Meeting of the British Medical Association held at Manchester in 1929. They will recall that in his opinion "the finished product is (1) a man who has a good knowledge of general pathology and an intensive knowledge of gynaecological pathology, (2) a man with a comprehensive knowledge of gynaecological and abdominal diseases, (3) an expert gynaecological and *abdominal* surgeon, (4) a surgeon who has formed the habit of looking at his cases from every viewpoint."

The collected papers of men who are the products of such a system of training are a glowing tribute to the way in which Dr. Cullen's ideals are achieved in practice. It is fitting that these volumes should be concluded by a record of the testimonial dinner given in honour of Dr. Cullen on the occasion of his seventieth birthday, a dinner at which tribute was paid by a gathering of 480 guests to a great gynaecologist, an inspiring and generous leader, and a man whose genius is excelled only by his humanity.

RELIEF OF PAIN

The Relief of Pain: A Handbook of Modern Analgesia. By Harold Balme, M.D., F.R.C.S., D.P.H. With an Introduction by Sir E. Farquhar Buzzard. Second edition. (Pp. 399. 12s. 6d.) London: J. and A. Churchill. 1939.

From time to time books appear dealing with a particular symptom and its treatment, and may be snapped up, perhaps too readily snapped up, by the busy practitioner who hopes he has found an easy road to therapeutic reputation. Too often he is disappointed, because symptomatic treatment can never be really satisfactory. That a second edition of this book has been called for in two and a half years shows that it has met a demand. It has certain merits that no doubt account for this. While comprehensive it is brief, making no attempt to enter into an erudite discussion of the whole of medicine; it from first to last insists that removal of the cause must be the only satisfactory way of removing pain, and it is well documented with plenty of references to facilitate further study. It will, of course, meet with criticism: the specialist reads such a book and finds it admirable in all specialties except his own, where he regards it as incomplete and insufficiently critical, and that, of course, is its danger. In bringing it up to date the author is forced to accept statements of enthusiastic supporters of some new surgical or pharmacological procedure which has not yet stood the test of time. Nevertheless this new edition is to be welcomed as a book of reference and as a stimulus to critical experiment in the use of various methods to give to the patient what he most craves for—relief from pain and suffering, whatever may be their cause. An excellent chapter is contributed by Miss Houghton on the nursing of pain.

BACTERIOLOGY

The Anaerobic Bacteria and their Activities in Nature and Disease. A Subject Bibliography. Volume I: Chronological Author Index. Volume II: Subject Index. By Elizabeth McCoy and L. S. McClung. (Pp. 295 and 602. 50s. net for two volumes.) London: University of Cambridge Press. U.S.A.: University of California Press. 1939.

Bacteria: The Smallest Living Organisms. By Dr. Ferdinand Cohn. Translated by Charles. S. Dolley. Introduction by Morris C. Leikind. (Pp. 44; 4 figures; frontispiece. 1 dollar.) Baltimore: Johns Hopkins Press. 1939.

Elizabeth McCoy and L. S. McClung have performed an unusual and valuable service to the science of bacteriology in compiling two large volumes entitled *The Anaerobic Bacteria and their Activities in Nature and Disease. A Subject Bibliography.* The material on which these volumes are based consists of about 10,500 separate references to original publications on this large subject. In the first volume these are arranged chronologically and alphabetically under the names of their authors; in the second they are very fully classified according to the aspect of the subject with which they deal. This elaborate and convenient method of presentation expands the original material into no fewer than 120,000 entries. The authors declare their intention of publishing further supplementary volumes in the future which will bring the publication up to date if the demand justifies this. Anyone seeking complete information from original sources on any matter within the scope of this compilation will have cause to thank the authors for making the task so easy.

A paper by Ferdinand Cohn published in 1872 entitled "Uber die Bacterien, die Kleinsten Lebenden Wesen" was translated and republished by Dr. Charles S. Dolley, then of the University of Pennsylvania, in 1881. This translation, together with brief biographical notes on the author and translator, has now been republished, and forms a useful addition to the few classical early papers on microbiology now made more easily accessible. Cohn's grasp of the significance of the subject was highly enlightened for that time, and among the ideas he puts forward is the possibility that life originated on the earth by the interplanetary transference of bacteria, a not impossible conception which was seriously discussed half a century after he wrote these words.

Notes on Books

Sir Edward Mellanby, Secretary of the Medical Research Council, delivered at Cambridge, on April 28, the Robert Rede Lecture, taking as his subject "Recent Advances in Medical Science: A Study of their Social and Economic Implications." An abridged version of this lecture appeared in the *Journal* of May 13 (p. 996). The lecture itself has now been published in full in booklet form (Cambridge University Press, 2s. 6d.). It concludes with these words: "There is no limit to the amount of knowledge to be gained if the medical scientist is given the opportunities and facilities for his work. Would that the same could be said about the wisdom necessary to make the best use of this knowledge!"

Comparative Studies Concerning the Strengths of Oestrogenic Substances by Dr. K. Pedersen-Bjergaard of Copenhagen is a monograph of 198 pages which gives an account of extensive experiments carried out by the author on the biological standardization of oestrogenic compounds. One of the chief problems dealt with is the reason for the prolonged action by esters of the type of oestradiol benzoate. The author concludes that the duration of action depends on the rate of absorption and produces evidence to show that oestrogenic substances after they have entered the circulation are inactivated fairly rapidly by the liver. The book is published in this country at 15s. by the Oxford University Press.

Income Tax Simplified, by Arthur Fieldhouse and E. Ewart Fieldhouse, sixteenth edition (Simpkin Marshall, 1s. 6d.), is intended to serve as a practical guide to the preparation of income tax returns, claims to repayment, etc., and to assist taxpayers not only to comply with the provisions of the income tax statutes but also to see that they receive the benefit of all the allowances and reliefs to which they may be entitled. Considerable trouble has been taken to supply helpful illustrations, and heavy type is freely—rather too freely—used to give emphasis to the points discussed. The general form lends itself perhaps rather to the use of examination students than to the convenience of taxpayers concerned with their own problems, but it is a clearly condensed statement of the essential features of the tax, and as such is good value for the price charged. The section dealing with partnership profits is less clear in explanation than might be wished. The statement that "when the capital of partners, their salaries or their share of profits are unequal . . . the tax should be deducted from the interest on capital, salaries, and profits" will puzzle some readers. The facts, of course, are that there is no "deduction" of tax; the most convenient method is for the assessment to be divided between the partners as if it were a divisible profit and the tax on each portion calculated and in aggregate agreed with that shown in the firm's assessment; each partner can then pay his share, either separately to the collector or into the firm's account if the firm as such pays the total tax assessed. The publication has been brought up to date, and though the explanations are necessarily brief they cover the whole field, including the assessment of tax on property, firm profits, salaries, etc.

Preparations and Appliances

IMPROVED METHOD OF ADMINISTRATION OF VINESTHENE IN DENTAL SURGERY

Dr. K. B. Pinson, Mr. R. Bradbury, L.D.S., and Mr. E. B. Jones of Manchester write:

During the past two years, at the Stretford Council Dental Clinic, we have been using vinesthene in conjunction with nitrous oxide and oxygen administered nasally from a modified Clarke's apparatus. The vinesthene is injected into the rebreathing bag from a 10-c.cm. Record syringe, and is used to (1) deepen the anaesthesia, and (2) reinforce the action of N_2O and O_2 so as to render this form of anaesthesia suitable for very young children. To do this the vinesthene has to be given slowly, after induction with N_2O and O_2. The chief difficulty experienced is that salivation is increased, which sometimes makes the patient cough or is otherwise troublesome. Another objection sometimes raised is that 6 c.cm. of vinesthene may be required. Otherwise the method is a very satisfactory improvement on ethyl chloride, owing to relaxation of the jaw and absence of vomiting, factors which render vinesthene the safer anaesthetic.

We decided to use vinesthene alone for short anaesthesia in the manner that Goldman has described. The anaesthesia was found to be good, but the manner of induction was unsatisfactory. It was difficult to get children of 3 to 4 years of age to co-operate by inflating the rebreathing bag, which was removed on inspiration and put back over the child's face for expiration, as recommended by Goldman. An ordinary type of N_2O three-way cock made with a wide neck and no inlet pipe was used, with a 1½-gallon rebreathing bag which was turned inside out after each case so as to permit of thorough cleansing.

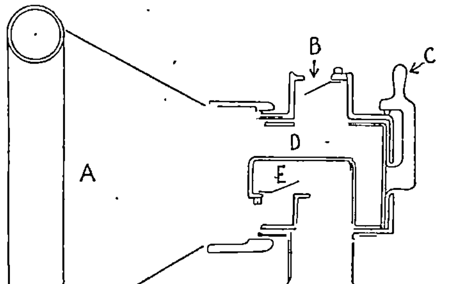

Fig. 1.—Diagram of altered cock. A. Face-piece. B, Valve for inhaling air. C, Cock lever. D, Cock. E, Valve for exhaling into bag. F, Bag-holder. G, Reversible bag.

It appeared to us that it would be advantageous if the mouth-piece could be left on the child's face during the complete respiratory cycle, so that the child could breathe in from the air and expire into the bag until it was filled. It would also help to gain the confidence of the child, since no anaesthetic would be given for the first half-minute or so. For this purpose we designed alterations to the existing valves, as shown in the accompanying diagram, from which it will be seen that (1) the expiratory valve is reversed, and (2) the inspiratory valve inside the cock is similarly altered by a built-up addition with a reversed valve flap so that on expiration the breath is directed into the bag, while inspiration is taken from the outside air.

METHOD OF INDUCTION

The face-piece is held gently on to the face. The lever on the cock is placed at the position marked "valves" until the bag is partly filled with expired air. It is then moved over to "to and fro" position, which allows inspiration from and expiration into the bag. Three c.cm. of vinesthene is then injected through a side tube in the bag-holder. The syringe is then removed to prevent breakage should the child try to knock the bag away. Neither N_2O nor oxygen are added. The apparatus is held on for sixty seconds, after which time complete dental anaesthesia is obtained, which lasts for about fifty seconds. We have found that the cock thus altered is a real improvement, and decidedly easier to use. Reversing the bag each time, too, gets rid of the smell of the anaesthetic, and little children are not upset by it.

In our experience this method has proved entirely satisfactory, and has enabled us to rely in most cases on the administration of vinesthene alone without the preliminary induction by nitrous oxide and oxygen.

The apparatus will be made by the Condensed Gas Co., Ltd., Rusholme, Manchester, 14.

THREE-WAY AUTOMATIC ADAPTOR FOR RECORD SYRINGE

Dr. I. David (Colombo) sends the following account of a three-way automatic glass adaptor manufactured for him by Adair Dutt and Co. of London.

Before the blood is drawn into the barrel of the syringe see that the valves move with each stroke of the piston. Air must be driven out if necessary by first filling the syringe with citrate solution or normal saline before the blood is drawn in. Even with a good syringe air will be sucked in unless the piston is worked slowly and steadily. Of course, every part must be airtight—namely, the piston, rubber tube connexions, nozzle, and the mount which receives it. It is better to hold the adaptor firmly against the nozzle of the syringe lest the former should drop down and break. I do not recommend a syringe of a larger capacity than one of 20 c.cm. I prefer a 5 c.cm. all-glass syringe, as I am of the opinion that in a smaller syringe there is not much chance of blood clotting or air entering. The adaptor is also useful for various other operations such as infusion, aspiration, and douching of cavities such as ear, nose, and vagina, and is also useful in administering glycerin and other enemata.

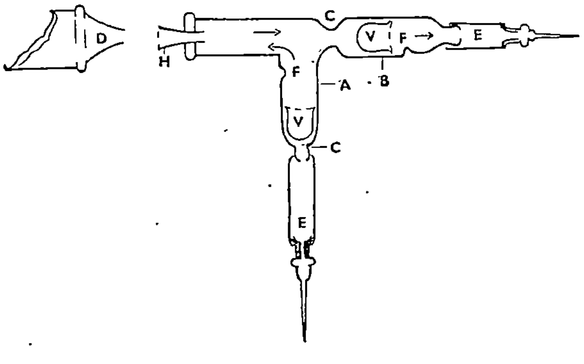

Fig. 1.—A, Aspirator or suction limb; B, injection or delivery limb; C, valve seat, which is closed by the valve V when in action; V, cup-shaped valve which acts in one direction only; D, nozzle of a Record syringe; E, rubber tubing; F, knob which prevents valves from closing delivery openings; H, removable metal mount to be taken apart when sterilizing.

A BLOOD TRANSFUSION DEPOT AT WORK

The experience of air raid casualties in the Spanish civil war showed that at least 10 per cent. were of a serious character requiring blood transfusion. With this in mind, as the international situation worsened, it was considered imperative in this country to organize a scheme for the empanelling of volunteers and the withdrawal, storage, and rapid distribution of blood for the large number of transfusions which might be necessary should air attack develop on a large scale. Four depots were accordingly equipped for the supply of the hospitals in London and the surrounding areas. A recent visit to one of these was instructive, and illustrated once again what brilliant improvisation the war emergency has evoked.

The depot, which is housed in the country at a social centre, is under the direction of Dr. Janet Vaughan with a staff of four or five other medically qualified persons, most of whom have had a large amount of experience in haematological technique. The staff includes also five non-medical technicians, and there is always a trained nurse in attendance to look after the donors. The depot is now open from 8.30 in the morning until 10 at night, and one of the medical officers sleeps on the premises to be ready for any emergency call.

Method of Organization

The organization of this effort began with the enrolment and testing of volunteers, originally at the town hall, as long ago as last Easter. The volunteers are mostly workers in the factories which abound in this area. Addresses to factory workers were given by the medical director of the depot, and the response was all that could be desired, both men and women coming forward with quite extraordinary willingness. Immediately a state of war was declared a large number of universal donors—healthy persons—were called upon, and bloods were withdrawn and stored in an ice house ready for dispatch to any hospital on demand. Up to the time of writing the only calls have been for transfusion for ordinary sick or accident cases, but there the organization is in readiness, as at other points in the home counties, should air raid casualties occur.

The panel of donors now numbers some 15,000. The mere card-indexing of such a number would be regarded as a very serious business indeed for the average city office, but in this depot they seem to take it in their stride. The enrolment form states the name, address, and business and private telephone number of the donor, whether he is under any national service obligations which might interfere with his availability, what is the general state of his health (whether, for example, he suffers from malarial attacks), and particulars of any recent serious illness. Then there is added on to the card the blood group, and, what is of less importance, the character of the arm veins. Each card is afterwards stamped with a serial number, the date on which the blood was taken, the quantity, and the result of the Kahn test. The serial number is also indexed on a separate card and appears on the bottle labels. It is considered an advantage to keep blood of all groups, and the different groups are indicated by differently coloured cards, blue cards for the universal donors.

The Human Element

The cheerful atmosphere of the main hall, with the couches, each lightly screened, not preventing conversation between the occupants while waiting or resting, possibly accounts for the fact that, notwithstanding the large numbers that have been dealt with, so few mishaps of any kind have occurred. A few donors have exhibited a transient faintness, evidently a psychological condition, and quickly combated by restoratives at hand. It was mentioned that of those who do faint almost all are men! Hardly any accident has been experienced, none at all of any seriousness, and some of the donors have professed themselves feeling better for what has been done to them, and have even intimated a desire to come back before the stipulated minimum interval (a month) to undergo it again.

The trolleys beside each couch are of standard pattern. Good lighting is provided, and bleeding takes place under strictly aseptic conditions. A sphygmomanometer cuff is put on and a steady pressure of 80 mm. Hg maintained. An anaesthetic, 2 per cent. novutox, is used, which has the advantage of being self-sterilizing. A neat appliance is a standard towel of unbleached calico, with a button slit which can be placed over the antecubital fossa in such a way as to make only one towel necessary instead of the usual two. That again is an idea adapted from the Spanish civil war. Another happy notion is the shape of the bottles in which the blood is collected for storage. They resemble pint milk bottles, but they have been given a special waist so that they never slip from the hand in spite of constant use.

Storage and Distribution of Blood

After the blood has been withdrawn and carefully tested for sterility the labelled bottles are packed in sliding wicker crates similar to milk crates, each containing twelve bottles, and kept in a large ice house, the temperature of which is between 2° and 4° C. One appearance which at first caused some misgiving was a scum which formed to a varying extent on the top of the stored blood, but the most rigid examination has proved that it is not due to any contamination; it seems to be partly fat and partly protein. Each bottle contains about 500 c.cm. of blood. The depot includes well-equipped sterilizing rooms with stills for distilled water and three large autoclaves which look somewhat primitive, but function excellently. In the little laboratory regroupings and Kahn tests are carried out—it was stated that there have not been many positive tests, fewer indeed than 1 per cent.—and advantage has been taken of the quiet time to do a certain amount of research. The fragility of the red cells in the stored blood has been investigated, and a complete haematological study of the blood from the day it is taken until the thirtieth day, when it is destroyed, has been made.

The bottles which are sent out on demand carry a label which it is requested shall be filled in by those superintending the transfusion and returned with the empty bottle. This label gives the date on which the blood was taken, and the completed particulars will furnish the date on which it was used, the reason it was needed, the name of the patient, any information as to clots or haemolysis, and the result of the transfusion. The label reads as follows:

> O Group IV
>
> Citrated Blood for Transfusion
>
> Mix without undue shaking and stand the bottle in warm water (not more than 40° C) for 15–20 minutes before use. Rotate occasionally. Use before (insert date).

The blood is sent to the hospitals in vans equipped with refrigeration plant, and as an example of how details have been thought out it may be mentioned that every hospital likely to be served has been routed, and the typewritten direction sheet is handed to the driver of the van. This is not the place to discuss the scientific results of the use of stored blood, but the war experience is resulting in a great deal of useful information which will be forthcoming at the proper opportunity.

Erythrogenic Toxin.—A method is described for preparing the erythrogenic toxin of *Streptococcus pyogenes* in very high concentration and a state "approaching" purity. It depends on the use of a broth which has diffused through cellophane, and the subsequent elimination from the culture of all the original constituents of the medium by the same process.—Studies on Haemolytic Streptococcus: I. Isolation and Concentration of Erythrogenic Toxin of NY 5 Strain of Haemolytic Streptococcus. II. Experimental Use of Purified Erythrogenic Toxins in Immunization against Scarlet Fever. M. L. Menten, H. H. Finlay, and A. H. Stock.—*J. Immunol.* June, 1939, **36**, 489.

SATURDAY OCTOBER 7 1939

A HISTORY OF TROPICAL MEDICINE

By writing his two volumes on the history of tropical medicine[1] Dr. Harold Scott has put many people in his debt; other medical historians, students interested in special diseases or in the health reforms effected, or in the strenuous lives he has chronicled, will consult his work. Their object in doing so may be to amend perhaps, more probably to amplify, most probably to borrow, but they will consult it. Of the Navy and Mercantile Marine, and the care and treatment given to the personnel, Dr. Scott writes:

> "The old-time naval surgeon excused himself for doing nothing, or perhaps we should say, justified his expectant treatment, by the conviction that 'two-thirds had such bad constitutions that no physician could save them, and the rest such good ones that all the physicians in the world could not kill them.' Sickness, moreover, was not encouraged. A man taken ill on board, if he did not speedily recover, was put on shore and treated for a month. If he was incurable or was permanently disabled, and was not one of the fortunate few to obtain admission to Greenwich Hospital, he was callously turned adrift to shift as best he could for himself."

The spread of knowledge with regard to the prevention of scurvy seems to have been an elaborately slow process among the higher authorities responsible for the health of sailors. In 1740–4 Lord Anson made a voyage round the world—"one of the most disastrous voyages in history." A note of the scurvy on two of the ships is given:

> "The havock which this dreadful calamity made in those ships was truly surprising. The *Centurion* from her leaving England, when at this island (Juan Fernandez) had buried 292 men and had but 214 remaining of her complement. The *Gloucester,* out of a smaller complement, buried the same number and had only eighty-two alive."

Yet we read that from the year 1600 onwards the East India Company had been quite cognizant of the prevention of scurvy by the use of oranges and lemons, and that these had been carried on board as part of the regular supply. Time brings its changes. In 1827 Goethe could write to Eckermann:

> "It is absolutely indispensable for the United States to effect a way through from the Gulf of Mexico to the Pacific Ocean, and I am certain they will compass it. This I should like to live to see, but I shall not . . . lastly, I should like to see the English in possession of a Suez Canal."

Goethe could no more forsee the difficulties of the Panama enterprise than could Lesseps himself. Neither of them suspected the dangers hidden in those pestilential swamps. None knew how many workers were destined to spend an all too brief existence there, scratching their innumerable insect bites, only to die miserably in the end from malaria and blackwater fever or yellow fever conveyed through these very bites. No wonder that the first undertaking, conceived in such complete medical ignorance, born and nurtured in an atmosphere more than a little tainted by commercial fraud, came to an end in bankruptcy. We are little surprised, the story of the failure having been told, when we read concerning Lesseps, the triumphant creator of the Suez Canal, that he became almost insane as a result of the fiasco of Panama.

The lower animals, invertebrate and vertebrate, play a remarkably large part in the dissemination of tropical diseases. Man is emerging more and more in the light of a casualty from accidental infection. He has often intruded into a cycle of animal disease which was going on before he arrived on the scene, and which will doubtless go on after he has disappeared from it. The skin of the tarabagan, *Arctomys bobac,* may have some value, but hardly enough to make it worth while running great risks on its account. Yet Scott relates that the Manchurian epidemic of pneumonic plague in 1910, which caused the death of 42,000 people, was due largely to the excessive zeal, coupled with the inexperience, of newcomers to the growing industry of hunting and skinning these animals. The old hands knew that sickly and dead animals should be left alone or dangerous illness would follow. Yellow fever, until only a few years ago, was accepted as a man—*Aëdes-aegypti*—man disease confined to the littoral of endemic regions. It is now found to be a widespread endemic of inland rural areas where *Aëdes aegypti* cannot be found—conditions the very reverse of the classical optimum, "a dense population, in a seaboard town, with abundant *Aëdes.*" Further, there is evidence that monkeys and possibly other animals may contract and recover from yellow fever. Malarial parasites morphologically indistinguishable from those which infect man have been found in chimpanzees, and desultory experiments are going on to discover whether or not they can infect man. It is held by some workers that the louse-borne virus of epidemic human typhus originates in an endemic typhus carried from the rat by its fleas. Rats are the reservoir of infectious jaundice and several human diseases. We have come to look upon American trypanosomiasis as normally a disease of various animals and tularaemia as a disease of rodents. Rats and their kind have indeed much to answer for to the human race.

It is of interest to try to follow the processes by which any great discoveries come to be made. Does the investigator, in the midst of his daily routine work or during his scant leisure time, find himself suddenly struck dumb at the moment of some divine inspiration? Here Dr. Scott helps us greatly in so far as the notable discoveries of tropical medicine are concerned. The divine inspiration theory will not bear long inspection, and certainly dumbness has never proved a prominent characteristic of discoverers. Sad though it may appear to the worshipper of heroes, it is nevertheless true that every discovery described in these volumes was preceded by a long prodromal period. During this time vague hypothesis had given place to a well-defined theory and even, in some cases, to well-planned experimental work which was within an ace of attaining success. There are many instances. Let the reader peruse, under the guidance of Dr. Scott, the history of yellow fever, and he will not be surprised that the names of Nott, Beauperthuy, and Finlay find honourable mention along with those of Reed, Carroll, Lazear, and Agramonte, and with those of Noguchi, Stokes, and Young of later years. Juan Carlos Finlay of Cuba enunciated his mosquito theory of the transmission of yellow fever at the International Sanitary Conference in Washington in 1881. He had already carried out experiments in which he had fed *Aëdes* on infected persons and then, at too short an interval as it turned out, on non-immunes. Or let him consider African trypanosomiasis. It was in 1895 in Zululand that Bruce discovered that the disease "nagana" of domestic stock was a trypanosomiasis transmitted by the tsetse fly. Now Livingstone, as far back as 1857, had frequently mentioned the fly, and specimens of *Glossina morsitans* had been brought to England and figured. Of the tsetse fly Livingstone wrote: "It is well known that the bite of this poisonous insect is certain death to the ox, horse, and dog." Trypanosomes in the blood of rats had long been known through the work of Lewis, and Griffith Evans as early as 1880 found them in the blood of horses and camels affected with "surra." Delafield, writing on malarial fevers in 1872, is quoted by Scott: "We find that the most constant lesion is the presence of little particles of black or reddish pigment in the blood. The pigment is in the form of flakes or of granules embedded in small, irregular, transparent, finely granular bodies. We also find the same transparent bodies without pigment." It remained for Laveran in 1880 to prove that the "transparent, finely granular bodies" were the cause, as well as "the most constant lesion," of malaria. Forde observed, then Dutton recognized and described, in a case of sleeping sickness the trypanosome called by him *T. gambiense*; but they did not associate the parasite with the disease. Bruce, Castellani, and others studied sleeping sickness but did not at first associate it with the trypanosome *T. gambiense*, which they also found.

[1] *A History of Tropical Medicine. Based on the Fitzpatrick Lectures, 1937–8.* By H. Harold Scott, C.M.G., M.D., F.R.C.P. Volumes I and II. London: Edward Arnold. (50s.)

It is because many people have usually had a hand in the making of a "discovery" that it is so difficult to allocate the just praise for it with any precision; this difficulty is well brought out in Scott's account of his historical research. Claims to discovery are apt to be not unlike the claims to have been instrumental in winning the battle of Waterloo. There are probably numbers of Bill Adams in all branches of scientific work; certainly tropical medicine has had its share. The discoverer is the man who puts two and two together; it is only by reading the history of most discoveries that we learn of the previous existence of the two and two. This explains many of the controversies between the supporters of Manson, Ross, Grassi, Bignami, and others concerning the discovery of the transmission of malaria and the mosquito theory. It explains the fact that ". . . France ascribed it to Laveran in 1891, Germany to Koch and Pfeiffer in 1892, England to Manson in 1894, Italy to Bignami and Mendini in 1896, and, not to be outdone, or thinking perhaps that numbers would make up for loss of priority, to Grassi in 1898." It accounts also for the many similar controversies on yellow fever, trypanosomiasis, and other diseases.

Lest any prospective reader should fail to obtain this book on the excuse that the particular disease in which he is interested may not find a place in it, the following are the contents: malaria, blackwater fever, yellow fever, human trypanosomiasis (African and American), leishmaniasis (kala-azar and cutaneous leishmaniasis), leprosy, cholera, plague, undulant fever, relapsing fever, melioidosis, dengue, amoebic dysentery and hepatitis, ankylostomiasis, beriberi, epidemic dropsy, pellagra, scurvy, poisonous foods—for example, from akee (*Blighia sapida*)—and ginger paralysis resulting from adulteration of ginger with triorthocresyl phosphate. Probably it is demanding too much, when a writer has expended so many laborious hours in research on his subject, that any reader should ask for still further efforts on his part. But there remain several diseases of the Tropics besides those dealt with in these two volumes which merit consideration on similar lines. Could Dr. Scott be persuaded to take a very deep breath and plunge into it once more?

"THE FOURTH ARM"

That finance is "the prop that sustains the whole of our war effort" is a truism that this country has successfully acted on in the past, and will have to bear very clearly in mind during the coming days of trial and strain. In this field of activity as in others the dearly bought lessons of twenty-five years ago are being restudied so that mistakes may be avoided and the country's maximum effort brought to bear on the issues of war at the earliest opportunity. This acceleration is noticeable in the promptitude with which steps are to be taken by the Revenue authorities to initiate an Excess Profits Tax, so that those whose businesses are so circumstanced that they become more profitable in time of war shall make special contributions to the Exchequer. The equity of such a demand will in general be conceded readily enough; the difficulty is that in so many cases the absence of a reasonably good standard of profits in recent years is apt to cause individual hardship. Various modifications are, however, provided which will apparently ensure at least "rough justice" in such cases. What is perhaps more important to the general public is that the tax should not operate as its forerunner, the Excess Profits Duty of the last war, too often did to make employers careless and uneconomical in the conduct of their businesses, with the result that waste and rising costs affected adversely the general level of prices and reduced the purchasing ability of the public. In that, as in other aspects of finance and industry, the ultimate safeguards lie in the good sense and patriotism of the nation, and an early realization of that fact should avoid disappointments in the future. In the meantime no reliable estimate can be made as to the probable yield of this tax; but excess profits are apparently the inevitable accompaniment of war conditions, and if they cannot be avoided at least they can be specially taxed.

So far as the income tax payer is concerned, Sir John Simon's demands for the current financial year have exceeded general expectation. The corresponding War Budget of 1914 raised the standard rate of tax from 1s. 3d. to 1s. 8d. The contrast between those figures and the present increase from 5s. 6d. to 7s. is an eloquent commentary on the difference in our general fiscal condition and on the sacrifice which taxpayers are to be called upon to undergo. The special provision for the relief of those taxpayers whose earnings have fallen as a result of the war will in some cases be very welcome, but the prospect of having to meet the increased demand in three or four months' time is a very serious matter for all of us. The indirect taxpayer is also required to contribute by increased taxes on beer, wines and spirits, on tobacco and on sugar—the last, the only increase in an involuntary indirect tax, is made avowedly so that no citizen, however humble, should escape some special contribution to the national needs. Of less immediate interest but of perhaps even greater ultimate importance is the Chancellor's foreshadowing of Government policy with regard to loan finance. The Empire's premier security—the loan issues of the British Government—set the level of the yield of trustee stocks, and thereby have a powerful influence on interest rates generally. Consequently a rise in the rate of Government interest not only affects the Exchequer directly but by its secondary results increases the cost of financing the running of a business, the acquisition of a practice, etc., and imposes a check on enterprise which is prejudical to the national well-being. It is to be hoped that when the Government applies to the people for subscriptions to a War Loan the rate of interest can be kept at a moderate level, and no doubt it was with that in view that the Chancellor referred to the further duties which citizens would be called upon to fulfil if the evils of inflation were to be avoided.

It is obvious that the nation must contemplate expenditure on a scale without precedent even in the last war, and it is almost equally obvious that the necessity and the accompanying obligation to meet it so far as possible by taxation of current income will be accepted, but only on one condition—namely, that waste shall be avoided or at least quickly detected and firmly and immediately eliminated. In that connexion Sir John Simon's appointment of "Treasury watch-dogs" to the spending Departments is a step in the right direction and should lead to good results. Some waste of money and effort is inseparable from so sudden and so immense an expansion of Government activity; but it must be kept to the irreducible minimum. If taxpayers feel that they are reasonably safeguarded in that respect they can be relied on to play their part to the end.

OPERATIVE ASEPSIS

We have referred on previous occasions to papers by Hart of Durham, U.S.A., on the prevention of infection in operation wounds. His belief is that operation sites, especially when extensive and long exposed, as in thoracoplasty, are liable to be contaminated by bacteria in the air, especially staphylococci. The method he proposes for preventing this is to expose the site and its surroundings to bactericidal light from a special mercury-vapour lamp, and the adoption of this precaution has actually led in his hands to a marked decline in the frequency of wound infections. In two further papers[1] he now describes experiments illustrating the bactericidal capacity of light from this lamp, and furnishes evidence, obtained by studying the healing of experimental wounds in rats after exposure to the lamp, that the reparative powers of various tissues remain unimpaired. This might appear to be the end of the story, and conscientious surgeons might feel obliged to install what is doubtless an expensive piece of apparatus in order to safeguard their patients against the risk of accidental infection. Nevertheless there is a flaw in the argument; as we have pointed out before, Hart's exhaustive studies do not explain how pathogenic staphylococci get into the air of his theatre in spite of all his earlier precautions. These included not only the frequent washing of the room, the provision of filtered air, the wearing of "large heavy" masks by all occupants (whether an operation was in progress or not), the exclusion of staphylococcus throat carriers, but even the imposition of silence on all occupants. Any one of the last three of these measures, faithfully carried out, might be expected to prevent contamination of the air from the throats of the theatre staff; yet according to Hart this was the source of infections which continued in spite of adopting all of them. He considers and rejects the possibility that their source is the patient's own skin, but an alternative not discussed in his papers is their origination from the skin of the surgeon. This is nevertheless the explanation arrived at by Devenish and Miles[2] after investigating the circumstances of a series of infections in clean operation wounds at University College Hospital. The wholesale exposure of agar plates in the theatre led in the first place to the conclusion that the average rate of fall of particles containing *Staphylococcus aureus* on an exposed surface with an area of 12 square inches was about 0.3 per hour, obviously an almost negligible risk. Comparison with Hart's original data on this point[3] is difficult because his results are very variable (from *nil* to fifty-one colonies per plate per hour), and since the majority of the staphylococci recovered were "non-haemolytic" and other tests more indicative of pathogenicity were not applied to them it is doubtful how many of them were in fact pathogenic. The task of Devenish and Miles was made easier by the fact that most of their unexplained sepsis followed operations by a particular surgeon. He was found to be a skin carrier of *Staphylococcus aureus,* and large numbers of these cocci were found in the sweat inside his gloves; they are presumed to have reached operation wounds through small perforations in the glove, and perhaps the most disturbing feature of this inquiry is the observation, based on the examination of some thousands of gloves, that the frequency of glove puncture during operation is 24 per cent., and remains as high as 14 per cent. in spite of precautions to avoid it. That this is the true explanation of this particular series of wound infections there can be no doubt, and it is so much more credible than Hart's hypothesis that one is tempted to grant it a more general application. If Hart is wrong about the source of infection in his cases but right about the beneficial action of his lamp, does this lamp actually kill staphylococci in the wound itself? This is a matter which it should be fairly easy to investigate, but in any event the next word lies with him.

---

ABORTION FROM CANCER SERUM AND URINE

Interesting observations on a selective action of urine and serum from cancerous patients on embryonic and newly growing tissues have recently been reported by Elsasser and Wallace[4] of New York. Their first observation was that the urine of a man suffering from an embryonic carcinoma of the testis gave a positive Aschheim-Zondek reaction, and daily intravenous injections of the urine into a twelve-day-pregnant rabbit produced abortion on the fifth day. Urine from other patients with tumours of embryonic type and from "a large number" of patients with other kinds of malignant tumours always caused abortion, usually within five days. Blood serum had the same effect. Urine or serum from "a considerable number" of normal individuals and hospital patients without tumours did not bring about abortion, nor did the urine of pregnant women. Cancer serum and urine caused a progressive necrosis, associated with filtration of inflammatory cells, in the placenta; in non-pregnant female rabbits the Graafian follicles degenerated or were destroyed, and the ovaries became small and sclerotic; in male rabbits the testis degenerated or spermatogenesis was suppressed. Cancer urine also gave rise to necrosis of a transplantable rat carcinoma; the necrosis started at the periphery and involved newly formed blood vessels as well as cancer cells. The substance responsible for these effects has not been identified. The authors did not advocate the use of these reactions as a diagnostic test for cancer, but the May issue of the *National Bulletin of the American Society for the Control of Cancer* states that the paper has been given widespread publicity, including mention on the front page of the *New York Times,* and that the society had therefore issued a cautionary notice. This refers to the bad reputation of serum tests for cancer, and states that the abortion test seems to have been employed only on cases where cancer was known to be present and had been diagnosed by other methods. Thorough investigation must precede the recognition of diagnostic value. Apart from their possible use in diagnosis, the reactions, if substantiated, will be important in the study of malignant processes. Independent confirmation and extension of the observations will be awaited with interest.

DISSOCIATION OF TUBERCLE BACILLI

Though by suitable cultural and animal inoculation methods mammalian tubercle bacilli can usually be divided into human and bovine types, occasional exceptions are encountered, the classification of which presents certain difficulties. Dr. Frimodt-Möller[1] has made a special study of these aberrant strains with particular reference to variations they may undergo in the laboratory, and has succeeded in showing that true, as opposed to mere environmental, dissociation may occur with the production of stable variants differing in cultural properties and sometimes in virulence from the original strain. The strains with which he worked were derived from human tuberculous material by cultivation on Jensen's modification of Löwenstein's medium containing 0.75 per cent. glycerin. It is believed that this strength of glycerin is insufficient to inhibit the growth of bovine but sufficient to stimulate that of human type bacilli. Twelve primary dysgonic human strains gave off in culture stable eugonic variants, while 39 other strains of human type, which were less eugonic than usual on primary isolation, failed to do so. Thirteen typical dysgonic bovine strains were examined. Of these, five formed eugonic variants of full virulence, and six formed eugonic variants of attenuated virulence, which, however, reverted to full virulence on a single animal passage. The remaining two strains were of special interest in forming eugonic variants which were completely and persistently avirulent, resembling in this respect the B.C.G. strain. Dissociation appeared to be favoured by acid in the medium, but to be more or less independent of glycerin. With one exception it invariably occurred in the direction of dysgonic to eugonic, or, as the author calls it, S to R. It is well known that in certain types of tuberculosis, such as lupus, variant strains may arise, some of which retain their characteristics in culture. It is also clear that variations may occur primarily in the laboratory. So far, however, no strain has yet been found to change in type from typical human to typical bovine or vice versa. Dr. Frimodt-Möller's monograph contains observations of much interest, which are presented in a clear and easily assimilable form. The initial historical introduction will be of special value to those who have been unable to follow the often complex results described by previous workers.

MEDICAL RESEARCH IN CANADA

The National Research Council of Canada has now issued its twenty-first annual report, a copy of which will be available in the Reference Library, Canada House, Trafalgar Square, London, S.W.1. Special mention is made of the formation of the Associate Committee on Medical Research under the chairmanship of Sir Frederick Banting, co-discoverer of insulin. The method of forming this committee may be considered as typical. Preliminary discussions by representatives of the Canadian Medical Association, the Royal College of Physicians and Surgeons, the Department of Pensions and National Health, and the National Health Research Council resulted in the calling of a conference for the consideration of all matters relating to medical research in Canada. At this conference a composite picture of medical research was obtained when each institution represented at the meeting reported on the scope of the researches on which it was engaged. On the recommendation of the conference the Associate Committee on Medical Research was formed. Since then the correlation of medical research in Canada has been fostered through interchange of visits by research workers and group planning of investigations in many fields. A distinct contribution to the furtherance of organized research in the medical field has thus been made. Similar committees function under the Council in many fields: aeronautics, asbestos, coal classification and analysis, field crop diseases, fire hazard testing, forestry, gas research, laundry research, leather, magnesian products, market poultry, metallic magnesium, parasitology, plant hormones, potato research, radio, radiology, survey research, weeds, and wool. Radium preparations in large numbers are measured and certified in the radium laboratory. Recently a device for rapid testing of radium tubes for leakage was constructed and a method for measuring the radium content of barium-radium bromide preparations was developed.

MALARIA IN MALAYA

The annual report for 1938 of the Malaria Advisory Board, Federated Malay States, records a noteworthy increase in the number of malarial cases admitted to hospital. The total figure, 51,300, compares with 35,500 in 1937 and 27,200 in 1936. These figures are stated to fall far short of the total incidence. Meteorological conditions during the year were unusual, the rainfall having been unduly low. The rise in incidence is, however, chiefly attributed to widespread replanting of rubber. The process involves the formation of large holes from which old trees have been removed and the digging of many other holes, often left open for some months to "weather" the soil, for the reception of planting material from the nurseries. Modern planting practice also requires terracing or the construction of silt pits on hilly land for the purpose of minimizing soil erosion. Collections of water and newly opened seepages thus formed provide many additional breeding places for anophelines, and, unless every precaution is taken, intensive breeding is likely to result. Although it has been found that anti-larval measures concentrated within a half-mile radius of habitations usually give reasonable protection, the investigations of Dr. W. E. Holmes, health officer, Kuala Lumpur, showed that *A. maculatus* could be taken at distances up to two miles from a replanted area, where breeding was intense. The mortality for hospital cases of malaria shows a satisfactory decrease, the percentage having fallen from 2.2 to 1.8. Diminished virulence of the parasites and/or increasing immunity of the population are suggested as possible contributory factors. To test the therapeutic value of prontosil in malaria twenty-seven subtertian and thirty-seven benign tertian cases were treated with this drug. The dosage was 1.5 grammes twice daily for seven days. It was found to be less efficient, both in antipyretic action and in its effect on the parasites, than quinine, while it cost more than three times as much. *P. falciparum* proved to be more susceptible to prontosil than *P. vivax.* With regard to the anti-larval oils experiments were carried out to test the effect of the addition of pyrethrum to the oiling mixtures. With the more active oils the only result was that the larvae died more quickly. The number that died was not increased. But with an oil of high boiling range it was found that the addition of pyrethrum increased not only the larval death rate but also the power to penetrate the tracheae of the larvae.

We announce with much regret the death of Dr. J. D. Comrie, physician to the Edinburgh Royal Infirmary, chairman of the Scottish Committee of the British Medical Association, and for many years a member of the Central Council and of the Journal Committee. Dr. Comrie was also chairman of the Central Medical War Committee for Scotland.

Professor J. H. Burn, M.D., has been nominated by the King on the advice of the Privy Council to be a member of the General Medical Council for five years in succession to Sir George Newman.

WAR WOUNDS AND AIR RAID CASUALTIES

The following article is a supplement to the series of lectures on war wounds and air raid casualties printed in these columns*

CHEMICAL WARFARE AND THE DOCTOR—I

BY

E. M. COWELL, C.B.E., D.S.O., T.D., F.R.C.S.,
A.D.M.S. 44th (H.C.) Division, T.A.

From the earliest times in the history of the world certain sociological, physical, and biological factors have governed the problem of the growth of population. Disease, as seen in individual cases, in epidemics, or in pandemics sweeping Europe in the Middle Ages, has from time to time decimated the population. War, with its horrors and vast numbers of men killed by disease and wounds, may be included in this list, together with famine, pestilence, floods, and earthquakes.

The present war, however, will be different and probably more horrible. While in former days war was an affair where men fought men, and women and children suffered accidentally or indirectly, to-day the idea is accepted by some Governments that it is justifiable for one nation to attempt to impose its will on another by striking a sudden swift crushing blow on vital vulnerable points in the country of its enemies. That is to say, civil centres are to be attacked in addition to, or apart from, definite targets of naval or military importance. For this reason many conferences have been held under the auspices of the International Red Cross of Geneva since the year 1920. The problem of protecting the civil population has now been accepted by every Government in Europe, including that of Great Britain, whose A.R.P. organization is so well known to all.

The subject of the medical aspects of chemical warfare is of grave practical importance to all medical men. It is not enough to be told how to treat the results of exposure to certain gases. As in typhoid, for instance, a study of the aetiology, pathology, and clinical picture is essential. In the present paper a list of substances most likely to be met with in chemical warfare is given, together with an account of their physical and chemical properties and a description of their physiological action. Their pathological effects will be discussed in the next paper.

History of Chemical Warfare

A full account of the history of chemical warfare may be found in a book published in 1935 by two French naval surgeons, Héderer and Istin. "Gas" is one of the most ancient devices used in fighting. Details are described by Thucydides of the method employed in the Peloponnesian War in the fifth century B.C. After months of siege, faggots impregnated with pitch and sulphur were set on fire outside the city walls. The wind drove on the cloud and rendered one point of the defence untenable. However, a thunderstorm broke, the rain extinguished the fire, and the first gas attack on record was unsuccessful. In the same campaign an efficient "flame projector" was designed and used. In 1726 Fleming described in his book *The Perfect German Soldier* several new poisons to be incorporated in grenades.

Chemical warfare fell into disuse for the next hundred years, and the British Government refused to sanction the use of toxic shells and grenades in the Crimea. In spite of the agreement of The Hague, 1899, chemical warfare was reintroduced in the Great War and enormously developed. Although occasional use of toxic shells by the Germans was reported from October, 1914, onwards, it was not until April 22, 1915, that chemical warfare was indulged in on a large scale. The Germans launched clouds of chlorine on a six-kilometre front in a surprise attack, causing 15,000 casualties, 5,000 of them fatal. In addition large numbers of prisoners and quantities of war material were lost to the enemy. The success of this attack depended on the element of surprise. No means were at hand to protect the troops. Major-General C. H. Foulkes, the officer in charge of the Special Brigade in France in the great war, writing in his book *Gas* in 1936, states that many warnings were received of this gas attack. These were not appreciated, however, until 1932. After the April, 1915, attack the matter was at once taken up by our Army Medical Service.

The first mask was immediately devised at the Royal Army Medical College, Millbank. This consisted of a pad of wool impregnated with sodium hyposulphite and tied over the mouth and nose by a length of veiling material. Large numbers of women workers were collected, and in three days the troops at the front were provided with 100,000 masks. In September of the same year chlorine was used by our troops at the beginning of the Battle of Loos. The attack was not very successful, and I remember seeing our own men admitted to a casualty clearing station later in the day with pink eyes and green buttons. Intensive work was carried out in the perfection of the anti-gas respirator, until finally an article was produced which was proof against all gases except carbon monoxide, and which permitted free action in fighting. In 1917 the Germans first used "mustard gas"—another surprise.

It is interesting to note that with the provision of respirators, introduction of gas discipline, and dissemination of a knowledge of chemical warfare, the casualties progressively diminished although the number of our troops in the field was enormously increased.

Agents used in Chemical Warfare

The most useful and generally accepted classification of war "gases" is the physiological one, determined by the action of these chemical substances in various parts of the body. The main groups are, in the order of their toxicity: (I) lacrimators (tear gas); (II) sternutators (nose irritants); (III) vesicants (blistering); (IV) lung irritants; (V) paralysants; (VI) gases met with accidentally, as carbon monoxide.

The following list is compiled from Vedder (1925, U.S.A.), with up-to-date additions.

I. *Lacrimators.*—Acrolein; benzyl bromide; bromacetone; bromobenzyl cyanide (B.B.C.); chloro-acetophenone (C.A.P.); dibrom-methyl-ethyl-ketone; ethyliodoacetate (K.S.K.); methyl-chlorsulphonate; monobrom-methyl-ethyl-ketone; xylylene bromide.

---

* Received for publication on August 4.

II. *Sternutators.*—Diphenylchlorarsine (D.A.)—Clark I; diphenylcyanarsine (D.C.)—Clark II; diphenylarsine-chlorarsine (D.M.)—Adamsite (or chloro-dihydro-phenarsazine); ethyl-dichlorarsine; *N*-ethyl-carbazol.

III. *Vesicants.* — Lewisite — chlorovinyl-dichlorarsine; mustard — dichlordiethyl sulphide (thiodiglycol chloride).

IV. *Lung Irritants.*—Chlorine; chloromethyl-chloroformate (palite); chloropicrine; cyanogen bromide; dichlormethyl ether; phenyl-carbylamine chloride; phosgene; stannic chloride; trichloromethyl-chloroformate (diphosgene or superpalite).

V. *Paralysants.* — Hydrocyanic acid; sulphuretted hydrogen.

VI. Gases met with accidentally—see Group III below.

In the *Medical Manual of Chemical Warfare* (H.M. Stationery Office, 1939) the following classification is suggested, with a view to combining both tactical object and physiological effect.

Group I.—Lethal: (*a*) vesicants; (*b*) lung irritants; (*c*) paralysants.

Group II.—Harassing: (*a*) lacrimators; (*b*) sensory irritants.

Group III.—Accidental (gases not used as weapons, as carbon monoxide).

The physical and chemical properties of the chemical agents most likely to be met with are briefly described below. The volatility of these substances is important. Gases may be persistent or non-persistent (P. or N.P.).

Lacrimators

Bromobenzyl cyanide (B.B.C.) (discovered in 1881), as commercially prepared, is a heavy, oily, dark brown liquid, very persistent, so that contaminated earth causes lacrimation after thirty days' exposure. B.B.C. corrodes metals except lead; it is expensive, and not likely to be used.

Chloro-acetophenone (C.A.P.) (1887) consists of white crystals melting at about 60° C. and with a high boiling-point and a low vapour pressure. It is very slightly soluble in water, but soluble in ether, alcohol, or benzene, and a hot aqueous solution of sodium carbonate. It smells of cheap scented soap. It is cheap, and easy to manufacture and store in shells or bombs, so that it is the substance most likely to be met with. It is non-persistent. It may irritate and redden the skin.

Ethyl-iodoacetate (K.S.K.) is a dark brown liquid, invisible in the gaseous state. It is persistent, and has a pear-drop smell.

Sternutators (All Non-persistent)

These substances form the "irritant smokes" and contain arsenic.

Diphenylchlorarsine (D.A.) (Clark I) (1878) is a thick semi-solid compound, slightly soluble in water but soluble in chloropicrin and phosgene. As a vapour it is a strong irritant, and when diluted is aromatic.

Diphenylarsine-chlorarsine (Adamsite) (1918) is similar, but is not soluble in phosgene. It tarnishes metals (D.A. does not), is easier to manufacture, and the toxic effects last longer.

These arsenic compounds are employed as mists or clouds. Both Groups I and II are easy to detect.

Vesicants

Lewisite (chlorovinyl-dichlorarsine), first made in America in 1918 and not hitherto used in warfare, is a heavy oily liquid darkening on standing. It is easier to detect than mustard, which in low concentrations may produce its effects before its presence is realized. The slight odour of lewisite resembles geraniums. It is soluble in oils, benzene, and the ordinary organic solvents. It is insoluble in water, but hydrolyses rapidly. This action is increased by heat and alkalis. The blistering concentration is given as 0.334 mg. per litre, which theoretically makes it an effective war gas. However, as it is so rapidly destroyed by water or aqueous vapour, and has not yet been put to a practical test, it is unlikely to be used in war. Lewisite is persistent, but less so than mustard.

Mustard (dichlordiethyl sulphide) was first used by the Germans in 1917, and manufacture of this substance by us was not completed until almost the end of the war. As in the case of chlorine, our Intelligence Service secured early information, the full meaning of which was, however, only understood at a later date. Mustard is a heavy oily liquid, in the pure state colourless and almost odourless. In quantities as produced commercially it is dark in colour and smells of mustard or garlic. It is highly persistent, and stable at ordinary temperatures. Heat causes decomposition into HCl and highly toxic lacrimators. Contact with water causes slow hydrolysis, which is hastened by heat. The resulting products are harmless—dilute HCl and thiodiglycol. Since its specific gravity is 1280 at 15° C., it readily sinks when added to water. Weathering will thus ultimately destroy mustard. Hypochlorites react violently with mustard, producing a non-toxic sulphoxide. This explains the use of "bleach" calcium hypochlorite.

Mustard is soluble in water to less than 1 per cent., but is freely soluble in the hydrocarbon oils, such as paraffin or petrol, and substances such as animal fats, ether, benzene, alcohol, acetone, carbon disulphide, etc. It is also readily dissolved in rubber, and permeates clothing, leather, wood, bricks, etc., like ink on blotting-paper. This property of penetration into most materials other than metals and substances with a glazed surface renders its destruction especially difficult. Mustard has a low vapour pressure, which explains why it vaporizes so slowly and is so persistent, and also the varying effects according to the temperature and humidity of the atmosphere.

This is the gas most to be expected in war. Of 36,965 gas casualties in the American Army, 27,711 were due to mustard (Vedder), and of the 160,970 gas casualties admitted to the casualty clearing stations of the B.E.F. 77.7 per cent. were due to the same cause. Exposure to a concentration of 1 in 1,000,000 is effective.

Lung Irritants

Chlorine is a greenish gas, 2.5 times as heavy as air; it therefore clings to the ground and fills hollows. It is easily liquefied; one litre of liquid chlorine at 25° C. will produce 434 litres of gas. Its pungent smell is well known. It is non-persistent. Pure dry chlorine will not corrode steel.

Phosgene ($COCl_2$; C.G.; carbonyl chloride or carbon oxychloride) is the most effective and lethal of the pulmonary irritants, but fortunately is completely resisted by the respirator. It is a liquid, boiling at 8.2° C. (46.8° F.). It is colourless, smells of "musty hay," and is 3.5 times as dense as air. It is non-persistent, and is easily moved on by the wind. Phosgene is readily hydrolysed, so that it cannot be employed in damp or rainy weather. The hydrochloric acid liberated in the presence of moisture corrodes steel, damages clothing, and destroys the tissues of the lungs. Soda-lime is used in the canister of the respirator to absorb phosgene. Phosgene will dissolve several of the toxic gases, and mixtures of mustard, chloropicrin, and the arsenic smokes may be expected. This gas is liquefied easily, as in the case of chlorine. *Diphosgene* (perstoff, superpalite, or trichloromethylchloroformate) is an oily liquid boiling at 128° C. It is heavier than phosgene, has the same toxicity, and is an intense lacrimator.

Chloropicrin (P.S.)—nitrochloroform—is a colourless volatile liquid, not hydrolysed by water, and semi-persistent. It also is a lacrimator. It is heavier than water, boils at 112° C., and is approximately 5.5 times heavier than air. It is killed by a solution of sodium sulphite in 50 per cent. alcohol. It has a penetrating odour and is strongly irritant. Exposure to frequent low concentrations may induce attacks of asthma.

Paralysants—These substances are not of much practical use in warfare.

Carbon Monoxide.—The management of carbon monoxide poisoning will not be dealt with in this paper.

Gas-detection Table

The following simple hints have been already published (*Pocket Book of First Aid in Accidents and Air Raids*, second edition, 1939, G. Gill and Son).

Part of Body Affected	Appearance	Smell	Chief Action	Gas
Eyes and nose	Vapour	Pungent	Tears	Lacrimator
Nose and throat	Mist	Faintly fruity	Sneezing	Sternutator
Lungs	Colourless	Musty hay	Cough	Phosgene
„	Green cloud	Pungent	Delayed collapse	Chlorine
Skin	Oily liquid	Garlic	Blisters	Mustard
„	Vapour nil	Geraniums	Redness and blisters	Lewisite

Chemical Analysis

In the issue No. 10 of volume 56 of *Chemistry and Industry*, published in 1937, appears a very important seven-page paper on analysis for the detection of poison gases by Studinger and Müller, translated by Mr. F. G. Crosse, F.I.C., from an article in "Mitteilungen aus dem Gebiete der Lebensmitteluntersuchung und Hygiene," 1936. Some of the items of chief interest are described in the following paragraphs.

PREPARATION OF THE SAMPLE

Visible drops are soaked up in filter papers held in forceps or ether extracts are made from contaminated soil. All operations are carried out in a fume cupboard, the operator wearing a respirator if necessary. Phosgene is detected by the reagent mentioned in C.I. below.

PRELIMINARY TESTS

(1) Using small test-tubes, the boiling-point is detected. (2) Decomposibility in water: a capillary loop of the extract is heated with about 0.5 c.cm. of water and tested with a 5 per cent. solution of $AgNO_3$. Mustard decomposes slowly; chloropicrin and the arsines do not decompose. (3) Tests for halogens in aliphatic compounds or in the side chain of the aromatic poison gases. (4) Pringsheim's test: a mercuric chloride test paper is coloured yellow by AsH_3. (5) Testing for nitrogen and sulphur: (*a*) the Prussian-blue test; (*b*) sodium nitroprusside—2 drops of 10 per cent. solution are added to the substance under test after being heated with sodium, a violet coloration indicating sulphide (mustard).

From Tests 4 and 5 poison gases can be classified:

C.I.—Gases resembling chlorine only: xylylene bromide, chloro-acetophenone, palite (chlorine-phosgene).

C.II.—Gases containing chlorine and sulphur. Mustard.

C.III.—Gases containing chlorine and nitrogen. Chloropicrin (HCN).

C.IV.—Gases containing chlorine and arsenic. The arsines and lewisite.

C.V.—Gases containing metal. Iron, carbonyl, lead, tetra-alkyls.

SPECIAL REACTIONS

Halogen Test.—Xylylene bromide boiled with alkaline potassium permanganate solution forms phthalic acid. This is isolated by extraction with sulphuric ether. The residue is heated to 250° C. with concentrated H_2SO_4 and a little resorcinol. Excess of soda lye gives a green fluorescence.

Chloro-acetophenone (C.A.P.).—A long test, where the substance is oxidized to benzoic acid with chromic acid, then nitrated and treated with ammonia and hydroxylamine HCl solution. The presence of ammonium diamino-benzoate is shown by a red-brown coloration on immersing the tube in hot water.

Phosgene is detected as diphenylurea or by a colour test paper. Air is passed over the sample into an absorption flask containing anil-water; an immediate white turbidity is produced. This is filtered off, dried at 70° C., and its melting-point determined (235° C.). Two tests are given with prepared test papers. In the second test a green coloration indicates phosgene. The reagents required are: (1) 0.05 to 1 gramme 6-nitroso-dimethylaminophenol dissolved in 50 c.cm. of hot xylene; (2) 0.25 gramme *m*-diethylaminophenol dissolved in 50 c.cm. of hot xylene. 5 c.cm. of solution No. 1 are mixed with 1 to 2 c.cm. of solution No. 2 and put on to filter paper. This paper when held in the air above the sample turns green.

Chlorine.—One gramme of soluble starch is dissolved in 100 c.cm. of water containing 5 grammes cadmium iodide and 5 grammes sodium acetate. A filter paper moistened with this solution goes blue when chlorine is present.

Mustard.—Eleven tests are given, all but one requiring the presence of liquid mustard. Of these the simplest is the sodium iodoplatinate test paper, 2 per cent. solution. This paper in the presence of mustard or an aqueous mixture of it becomes purple-red, then blue. In this country yellow detector disks are provided which become red in the presence of liquid mustard. The chemistry of this test is secret, but it probably depends on selenium.

Grignard's test will detect the vapour of mustard. 20 grammes of sodium iodide are dissolved in a little water and an aqueous solution containing 1.65 grammes of copper sulphate is added. Into this mixture is stirred 2 c.cm. of a solution of 35 grammes of powdered gum arabic in 100 c.cm. of water. The whole is made up to 200 c.cm. and the cuprous iodide filtered off. This clear solution is stored in a brown bottle. When mustard vapour is passed through 3 c.cm. of this reagent a turbidity appears due to the formation of di-iodo-diethyl sulphide.

Chloropicrin.—Four tests are given. Of these the simplest is Labat's. One drop of chloropicrin extract is added to 2 c.cm. of 5 per cent. alcoholic potash lye. When a small crystal of thymol is dropped in a yellow colour appears. Several supplemental tests are given, which need not be described in this paper.

Summary

A sound knowledge of the chemical poisons which may be used in modern warfare is the preliminary essential to a complete acquaintance with clinical diagnosis, management, and treatment of casualties.

An intimate chemical study of all the "gases" will interest only a few experts, but a working knowledge of their physical and physiological properties should be acquired by all medical men as soon as possible.

(*The second part of this article will be published next week.*)

RED CROSS AND ORDER OF ST. JOHN

JOINT WAR-TIME ORGANIZATION

The British Red Cross Society and the Order of St. John of Jerusalem have amalgamated for the duration of the war, as they did during the war of 1914–18. A Joint Emergency Committee has been formed, and work is actively proceeding in many departments. The department of medical personnel is presided over by Lord Horder; that of nursing by Lady Ampthill and Dame Joanna Cruickshank, late matron-in-chief of Princess Mary's R.A.F. Nursing Service. The transport of wounded is under Sir Alexander Roger, director of the motor ambulance department of the Red Cross; Viscount Falmouth supervises the central hospital supply services; the Earl of Clarendon the work for prisoners of war and for wounded and missing; Lord Stanmore the auxiliary hospitals and convalescent homes; and Sir Charles Howell Thomas the very important matter of stores. The International Red Cross of Geneva has appointed a liaison officer—a Swiss gentleman, who is now in London.

Nursing Services

Neither of the two organizations which have now amalgamated has any recognized trained nurses' department in peace time; such a department functions only in war, and it has now been organized. Its task is mainly to deal with the nursing services of auxiliary hospitals and convalescent homes, and its first obligation is to the military authorities, but this time its activities are being extended to cover certain civil requirements, including those of maternity institutions. The nursing activities of the Red Cross are at present, as Dame Joanna Cruickshank explained to our representative, still in the preparatory stages, and their expansion will necessarily depend on the development of hostilities on the Continent. Meanwhile, a new uniform has been provided for the Red Cross nurse. It is designed with a view to comfort and ease in moving about and includes a low soft collar and soft cuffs. The V.A.D.s are again prominent, and there are many hundreds of V.A.D. depots in the country. This department is under the direction of Dame Beryl Oliver.

Gifts to the Red Cross

Meanwhile, in spite of the impoverishment caused among large sections of the community owing to the war, the Mansion House Fund continues to attract public support. Some of the gifts received have caused a certain embarrassment. The other day an anonymous donor contributed an eighteenth-century diamond necklace of unusual size and brilliance which has been valued by experts at £30,000. The problem is how to realize such a gift. At a sale by auction it would probably fetch nothing like its real value. The suggestion of a lottery has been made, but that method at present is illegal. Possibly the Chancellor of the Exchequer may be asked to pass a short Bill through Parliament legalizing such a method strictly for Red Cross purposes during war.

Aerial Ambulances

An event which has caused concern in Red Cross circles is the shooting down of a Red Cross aeroplane over Germany and the killing of an American woman doctor whom it carried. Article 18 of the Geneva Convention lays it down that an aeroplane is just as lawful a means of carrying wounded as an ambulance train, but that it must have the Red Cross properly painted on its wings, must not carry any national emblems (such as the swastika or tricolor), and must come down on demand. It is possible that the aeroplane in which this woman doctor was travelling failed to come down on demand. Aeroplanes are unlikely to be used to any great extent for the transport of wounded. The International Red Cross Conference which met in London last year asked the national societies to organize courses of training in aerial transport; but the carrying capacity of aeroplanes is very limited, and, moreover, while ambulance road vehicles can be readily replaced, it is not so easy to replace the ambulance aeroplane.

If any doctors wish to write to the Red Cross offering their services or making inquiries it will save time if their letters are addressed in the first instance to 2, Chesham Place, S.W.1. Doctors' wives and others who may like to make gifts or undertake work for Red Cross purposes may be interested to know that the urgent need of the moment is for wool in any shape or form, and any gifts of the kind will be greatly appreciated by the department which deals with the central hospitals supply services at the Victoria Club for Ladies, 9, Halkyn Street, S.W.1.

LONDON MILK SUPPLY

The London County Council reports an investigation, conducted some time before the outbreak of war, to discover the amount of liquid milk consumed daily in London and the treatment (if any) to which it is subjected. The daily consumption of milk in the county of London is 460,000 gallons. Information as to the treatment of 437,231 gallons is available, and shows that of this amount 405,162 gallons, or 92.7 per cent., is pasteurized, 10,191 gallons sterilized, 15,691 gallons processed, 1,696 gallons tuberculin-tested, and the remainder, 4,491 gallons, is ordinary raw or other untreated, including accredited, milk. Licences for the pasteurization of milk are held in London by twenty-eight dairymen, the depots being situated in fourteen boroughs. It is a matter for regret, says the Council, that as a minimum the proposals concerning pasteurization made in the Milk Industry Bill, 1938, have not been incorporated in the Milk Industry Bill recently introduced into the House of Commons. It is also regretted that if the term "accredited milk" is retained, no provision is made to ensure that such milk shall be of at least a better standard as regards the presence of tubercle bacilli than ungraded milk. Milk to be sold under the designation "accredited" must not at any stage be treated by heat. The use of the designation conveys the natural impression that such milk is of particularly high quality, and certainly higher than ungraded milk. A random analysis of samples of milk arriving in London in churns points to the conclusion that such a natural impression is unfounded, as the percentage discovered to be tuberculous was persistently higher in the accredited than in the ungraded milk. Since the beginning of 1938 the sampling has resulted as follows:

Year	Quarter	Ungraded			Accredited		
		No. of samples	Number tuberculous	%	No. of samples	Number tuberculous	%
1938	First ..	371	22	5.9	130	13	10.0
	Second	435	32	7.4	75	9	12.0
	Third ..	379	27	7.1	98	10	10.2
	Fourth..	434	32	7.4	83	13	15.7
1939	First ..	461	32	7.0	123	9	7.3

The results of this analysis of milk samples have been communicated regularly to the Ministers of Health and of Agriculture and Fisheries with a view to action being taken to remedy the unsatisfactory position.

Prostitutes.—The psychiatric examination of fifty-four prostitutes showed that one-fifth were to some degree mentally defective, a majority were constitutional psychopaths, and less than a fifth were comparatively normal. Nine-tenths had had venereal disease, usually both gonorrhoea and syphilis. Over half had severe physical handicaps. Almost all were addicted to alcohol, and some took other drugs. Forty-seven of the fifty-four had never engaged in any other occupation.—Psychiatric Examination of Female Prostitutes in Sweden. G. Jonsson.—*Acta psychiat.* 1938, **13**, Fasc. 4, 463.

HOSPITAL BEDS FOR CIVILIAN SICK

According to a statement issued from the Ministry of Health, the hospitals are acting upon the Minister's instructions that the arrangements for treatment of casualties must not be allowed to deprive the civilian sick of in-patient treatment for ordinary illnesses, if their condition requires such treatment. It is the Minister's intention that all the available accommodation in general and special hospitals should be pooled and used to the best advantage to meet the individual needs of each area, whatever they may happen to be. Great importance is attached to the maintenance of residential accommodation under the tuberculosis schemes of local authorities. Sanatoria and hospitals for tuberculosis should continue to function and to receive patients, especially those in the infective stages. Again, patients suffering from cancer, particularly those in the early stages of the disease, should be admitted to hospital for treatment. The Minister will issue a circular to local authorities giving guidance in these matters in greater detail. Meanwhile every possible assistance in planning hospital accommodation for the ordinary needs of the civil population will be given to medical officers of health by the Ministry's principal regional medical officers and hospital officers. The hospital officers are ready to advise on the number of hospital beds that can be allotted in an area for sick persons, while maintaining the necessary quota of beds for possible civilian and Service casualties.

Local News

ENGLAND AND WALES

Merger of Newcastle Hospitals

At a special court of the Royal Victoria Infirmary, Newcastle-upon-Tyne, held on September 30, the governors approved in principle the scheme for merging Newcastle hospitals, and the house committee of the Infirmary was empowered to effect mergers with the other institutions—namely, the Newcastle-upon-Tyne Eye Hospital, the Throat, Nose, and Ear Hospital, the Babies Hospital and Mothercraft Centre, and the Hospital for Sick Children. The purpose of the merger is to bring about economies in the working of the different hospitals, and by bringing the various institutions into closer co-operation to make them more advantageous to each other. Under the scheme, which will probably become operative at the end of the war, each institution will preserve its identity, and each will be separately governed and separately financed. It should provide for increased collective activity and concentration of opportunities for service and training.

London Midwifery Service

The London County Council has arranged to continue the domiciliary midwifery service and the maternity units in hospitals. Thirty temporary midwives have been appointed to supplement the permanent staff of seventy midwives. In view of the possible unreliability of postal and telephone services in war time, which might interfere with close relations between the head office, voluntary organizations, and domiciliary midwives, the midwives have been formed into self-supporting groups with leaders and deputy leaders. The leader's responsibility is to allocate bookings, distribute emergency calls, requisition drugs and supplies, and collect necessary records. Facilities are available for dealing with obstetrical emergencies. The effect of the evacuation of expectant mothers cannot yet be determined. It has to be borne in mind that the maternity beds in the London hospitals have been reduced in number by two-thirds, and that some of the evacuees are returning to London. It can be definitely stated that the work of the domiciliary midwives has increased owing to the additional ante-natal work to be undertaken as a result of the closing of borough clinics, the extra time taken to visit patients at night due to reduced street lighting, and the extra work thrown on leaders of the groups through decentralization of administration. The period of nursing has been reduced from fourteen to ten days, and twice-daily visits have been limited to three days instead of four from date of confinement. The rules in regard to refresher courses have been waived by the Central Midwives Board and courses arranged have been cancelled. All forms have been revised so as to supply only essential records and to reduce clerical work to the minimum. Arrangements have been made for certain hospitals, both council and voluntary, to continue to maintain a maternity unit, and the number of beds will be increased or reduced according to circumstances.

L.C.C. Reports

The annual reports of the London County Council extend to eleven separate volumes or parts and have been criticized on the grounds of being bulky and unbalanced. It has been decided that the only volumes to be issued annually shall be the report of the county medical officer of health, the report of the school medical officer, and the medical supplement, containing a series of papers and reports on purely medical subjects selected from contributions by members of the hospital and central medical staff, and the continuance of this last-named volume is also to be reviewed next year. The present annual report of the mental health services is not to be continued in a printed form. In most of the other departments of the Council's work it is not considered that an annual report is necessary, and instead of this a triennial general report will be issued. The reasons for the medical reports continuing to be issued annually are that the report of the county medical officer of health is the only report which comments on the vital statistics of the county, that it includes a comprehensive review of such subjects as housing, milk supplies, venereal diseases, tuberculosis, and the midwifery service, and that the issue of such a report is a statutory obligation on every other medical officer of health in the country; while the report of the school medical officer also is a requirement of the Board of Education.

First Red Cross Flag Day of the War

By means of flag days organized in the streets by individual hospitals citizens of London have in the past been in the habit of contributing large sums, chiefly in pennies, for the upkeep of their hospitals. Two years ago these flag days were combined, and instead of seventy-seven flag days held in London the hospitals organized two only, one in May and the other in October. Preparations were already made for a flag day on October 10, when it was announced that the Central Committee of the London Hospitals Street Collections, through its chairman, Lord Luke, had offered this flag day to be organized on behalf of the Lord Mayor's appeal for the joint organization of the British Red Cross and the Order of St. John. In accepting this offer the Lord Mayor stated that he was inviting others to co-operate throughout the country with the object of extending this London flag day into the first national Red Cross Flag Day of the war. In the short period of time at disposal a great burden of work will be thrown upon the workers giving assistance. Additional voluntary workers who are urgently required should offer themselves as soon as possible either to the mayor in their borough, or to Lord Luke, Chairman, Hospitals Day, 36, Kingsway, W.C.2.

Work at Papworth

The report for 1938 of the Papworth Village Settlement records generous gifts from Sir Edward Meyerstein and an anonymous donor towards the equipment of a large workshop, which is to be named after Mr. Chamberlain. The director, Sir Pendrill Varrier-Jones, reviews the difficulties encountered in the development of Papworth as an industrial enterprise, happily solved through the sympathetic collaboration of the Ministry of Health, the Friendly Societies, and the Trades Unions. Reviewing the future from the national point of view, Sir Pendrill claims that the way is now clear for the division of industry into two grades, the first profit-making, the second non-profit-making. In the former category only fit men can be employed; Papworth belongs to the latter category. Sir Pendrill further points out that if second-grade industry had the benefit of the saving it effects it would be almost, if not quite, self-supporting. For example, men, women, and families now settled at Papworth would be drawing £17,500 a year in unemployment benefit if they were not at the settlement. Instead they paid, during 1938, £1,090 into Government insurance funds, while Papworth industries, their employers, contributed a further £1,131. Given this annual total of nearly £20,000, Papworth could provide the service of a sixty-year 3½ per cent. loan, more than large enough to build the entire settlement. The wide application of the Papworth experiment to the vast problem of disablement would not only be a financial benefit to the country, but would also remove from the disabled a legitimate source of grievance. "And let it not be forgotten that the most dangerous agitators, the most successful revolutionaries, have been the men rendered bitter by privation and disease."

At the annual meeting in London the president, H.R.H. the Duke of Kent, alluded to the work of Dr. Brown Cruickshank, carried out in the Papworth research department. Lord Willingdon, the chairman, said that wages to a breadwinner were often almost as vital to health as medical treatment, and that Papworth had associated the two in a big centre of social medicine. Sir Pendrill Varrier-Jones stated that the personal interest of the Royal Family had contributed largely to the development of Papworth. All the royal luggage for the Canadian and American tour was made at the settlement.

SOUTH AFRICA

The Capetown Health Report

Vital statistics recorded in the annual report for the year June 30, 1938, of the medical officer of health, city of Capetown, compare unfavourably with the figures for the preceding five years. The death rate showed an increase of 2.4 per cent. in Europeans and 4 per cent. in non-Europeans. On the other hand there was a decline in infant mortality of 9.4 per cent. in Europeans and 4.9 per cent. in non-Europeans. The depressed social and economic conditions of the non-Europeans, operating through under-nourishment, bad housing, overcrowding, and low cultural standards are reflected in classified mortality rates. For example, deaths under 25 years of age were 17 per cent. of the total in Europeans, 58 per cent. in non-Europeans. From tuberculosis the death rate in non-Europeans was 5.8 times as great as in Europeans. In infants under 1 year of age the death rates from measles, respiratory diseases, and diarrhoeal diseases were respectively 2.3, 4.8, and 6.2 times as great in the one race as in the other, and in infants between 1 and 2 years of age the corresponding rates were 5.9, 6, and 23.6. The report states that no new houses were built by the city council during the year under review, and that overcrowded and insanitary conditions are still all too frequent, not only among the coloured population but also among certain of the poorest of the Europeans. Houses affording reasonable accommodation for one family are often sublet to several, and in many cases whole families live in single rooms. In a recent survey of an area in Central Capetown, with a population exceeding 45,000, of whom 91 per cent. were non-Europeans, more than half were found to be living in single-room lettings; in another area one-third of the population were in a similar predicament. Despite extension of sewerage schemes many areas in the suburbs are still without proper drainage, and in June, 1938, faeces were being removed by men and wagons from nearly 6,000 premises dependent on pail closets. Among efforts to ameliorate the condition of the poorer sections of the community is a State-aided milk and butter scheme. The butter is sold at 6d., 5d., and 4d. a lb. for the first, second, and third grades respectively. Unfortunately the privilege of purchase is restricted to Europeans and Cape coloured; natives and Indians, despite the representations of the city council, are excluded. Milk is supplied to school children at a charge of 2s. per quarter, partly or wholly remitted in cases of poverty. During a temporary milk shortage cheese was supplied to coloured schools: 7,376 Europeans and 23,616 coloured children received a half-pint of milk or an ounce of cheese daily.

Correspondence

Radium Precautions

Sir,—In your issue of September 16 (p. 614) you say the Radium Commission would like to hear of any suggestions for resuming radium therapy. I have a simple one to make: pull the radium needles out of the bore holes and use the radium again. In common with many other radiologists, I think that this burying of radium needles is quite unjustifiable. It was done, I know, on the advice of some experts, but I am convinced it is a panic measure, based on a very faulty estimate of the dangers involved.

Think of the sequence of events necessary to cause a serious risk of radium poisoning. A bomb must hit the building, penetrate to the basement (where obviously the radium safe would be), burst wide open a heavy steel safe, and scatter into small fragments a large almost solid mass of a plastic metal, lead. It must then split open a considerable number of tough, malleable platinum containers (each of very small mass) and disperse widely the contained radium salt.

And now please draw up a balance sheet. Place on the credit side the hypothetical prevention of loss of life from this chain of improbable possibilities. On the debit side place the lives lost because radium therapy is withheld, and note the hopeless imbalance. So far the "black-out" accident cases and these cancer patients have been the principal British casualties. I submit that a sense of proportion in those in charge of the nation's radium would have lessened the number of the latter.—I am, etc.,

London, W.1, Sept. 26. S. Cochrane Shanks.

Organization of the Emergency Medical Services

Sir,—I quote from the article by Lieut.-Colonel W. A. Lethem which appears in your issue of September 23 (p. 656): "Probably a very high percentage of all casualties will be classified as orthopaedic, and at first will have to be admitted to any surgical hospital, though in time special types of case will be transferred to the care of surgeons with specialized experience." This is not the best treatment for orthopaedic cases. "In time" is a very elastic phrase. The cases may be a long time before they get to an orthopaedic hospital. Meanwhile in the stress of circumstances and for want of the "surgeons with specialized experience" undue suffering and avoidable crippling may result, and individuals will become an unnecessary financial charge on the country. Therefore, both on humanitarian and on economic grounds, these cases should reach a special orthopaedic hospital at once. I do not think that this is impossible. I wrote a letter which appeared in the *Times* of August 9 last to urge it. I recall the efforts of Sir Robert Jones in the last war which resulted, after some interval, in the establishment of special orthopaedic hospitals. I only wish that he were alive now to exercise his powerful influence in the direction which I advocate.—I am, etc.,

Cardiff, Sept. 27. A. W. Sheen.

Doctor and Patient in War Time

Sir,—The recent correspondence on the subject of war neuroses raises a subject of wide interest—namely, a doctor's influence on and his method of first approach to his patient. It is our ordinary task as doctors to give our patients courage in their illness and confidence in their recovery. Obviously in regard to material things a man cannot give what he has not got. This is equally true of emotional and spiritual things. Some men are fortunate in the firmness of their faith, and in having such a surplus of courage and confidence that their very presence is a help to their patients. For those of us who have not such surplus power as may be called for in the care and treatment of war-shattered patients there are two ways in which we can help ourselves to help them.

First, I believe that what we continually, consciously, and purposely think becomes a habit and affects our attitude of mind. We should therefore take pains to determine that our own thoughts are those of courage, confidence, faith, and hope. We must sedulously refuse every thought of fear, regret, resentment, and the like, because these thoughts arouse emotions that have a weakening effect. In other words, if it is not already our habit, we must set ourselves at once the task of collecting good stuff to give away to our patients. Secondly, let us mark the importance of words, both because of their meaning and because of their associations. Word associations are especially important, because they may become so strong that the original meaning of the word is lost.

With these things in mind, and realizing the effect of a first impression, it is interesting to reflect how often the first words spoken by a doctor to his patient are, "What do you complain of?" The reply may be in terms of a bad pain or other disquietening sensation, and quite often our next remark is, "I am sorry." And so the first word we use to our patient is complaint, a word that suggests something wrong, a word that opens the door to actual fear. The next word is "sorry," a word that suggests self-pity. What worse sensations than fear and self-pity can we offer to those who come to us for help? Surely we should forget the word "complaint," and only when we weakly allow ourselves to indulge a patient may we allow ourselves to pity.

The first question we put to a patient cannot of course be positive and certainly not buoyant. But it can be colourless, or, better, it can contain the idea of acceptance. It may seem difficult to think of opening questions on either of these two lines. With practice there are a number to be found. Needless to say the whole history of symptoms (better called sensations) should be taken on the same positive level of acceptance, or, failing this, on the colourless plane of kindly inquiry.

In making these suggestions it is in my mind that the doctor who is going to look after war-worn persons should first have thought as to his own attitude of mind and his method of approach to his patient. Generally we think of our patients first!—I am, etc.,

St. Albans, September 25. Geoffrey Evans.

Psychological Casualties in War

Sir,—I read with particular interest Dr. Maurice Wright's two articles on psychological emergencies and casualties (*Journal*, September 9, p. 576, and September 16, p. 615) because first as a battalion medical officer during the last war and secondly as a psychotherapist with the Ministry of Pensions in the following years I arrived through experience at certain views.

I have not so far seen anything published which suggests that the Ministry of Health is making any real preparation for psychological casualties. These casualties will be heavy among the civilian population, whose resistance has not been fortified by discipline and esprit de corps. Such casualties have the worst possible effect on morale. The civil population is inured to street accidents and injuries at work, and physical casualties will not differ greatly from these, but they are not used to psychological casualties and will suffer from them. Such cases are positively infectious and must be evacuated and kept away until they are rehabilitated. Moreover, they should not be detained in C.C.S. or other hospitals, but cleared as soon as possible to the appropriate special hospital, where their treatment can be carried out. The shorter the time between injury and the beginning of psychological treatment and the less the interference *en route* the quicker the cure.

I hold no brief for any "rapid" method of treatment, having seen as battalion medical officer many such cases when returned to duty. If they did not relapse they were generally quite useless, as no one felt inclined to trust to them in emergency. All supporters of rapid methods appear to me to be optimists. Sir Arthur Hurst (September 23, p. 663) is no exception. I worked in four different "shell-shock" hospitals, and relapsed Seale Hayne patients were admitted to all of them, and were generally found to have no insight into their condition.

I view with horror Dr. Wright's supposition that psychological hospitals will be large, admitting both sexes and all ages, types, classes, and even races. I feel that no psychological hospital should contain more than sixty or seventy patients with three medical officers and a superintendent. Dr. Wright mentions the urgent need of all neurotics for security, and as they cannot be expected by any means to gain this feeling in a danger area their hospital must be placed in as safe a position as can be found.

As to the shortage of psychotherapists, there must be many, like myself, too near the age limit to volunteer for the R.A.M.C. but who would be glad to resume the most interesting of medical work if they are required—as they will be. If we are considered too out of date as psychotherapists, which remains to be seen, I suggest that our previous experience might commend us as superintendents of psychological hospitals, where we could at least show our ability to understand and appreciate the work of the staff and the meaning of the "psychological approach." This was not always so in my past experience.

I should be glad to hear that the Ministry of Health was taking over country houses or small hotels in Cumberland, Westmorland, West Yorks, Wales, Devon, and Cornwall, and staffing them for this purpose. Such hospitals have the great advantage from the Treasury point of view that they require practically no expensive equipment.—I am, etc.,

Barton-on-Humber, Lincs, September 26. John A. Tippet.

Sir,—As neurologist to the Medical Research and Intelligence of the A.E.F. in France part of my duty in 1917 was to visit frequently the front stations as well as the base hospitals where neurotic casualties were dealt with in order to ascertain the best methods of rehabilitating men thus disabled.

Before the inauguration of successful methods in 1916, thousands of men had been relegated to base hospitals, where they were lost to the Service for months, and many for years, while I was informed that in England the losses were at least 100,000, most of these having been permanently discharged from the Army and their usefulness ended.

At the conclusion of the war the French method had been so perfected that there were left only eighty-seven intractables. Even then these were not discharged, the policy being to return them to civil life only when rehabilitated.

In order to send back the thousands of casualties to the fighting force without the long delay impracticable in warfare it is evident that no elaborate reconstruction of personality is feasible. Methods used must be rapid. It should also be evident, except to those ridden by *a priori* theories, that men who have adapted themselves to civil life and army training, and warfare for months are not chronic misfits in need of complete readjustment. This is also true of the neuroses of civil life, in the treatment of which the coat should be cut to fit the cloth and not tailored to pattern, as theorists would have it.

Hence the disabling symptoms of an evacuated war neurotic were usually removable by rapid re-education, reinforced by the collective mass suggestion of a carefully devised environment in special centres where the exact methods varied with the individuality of the neurologist in charge, although all were based on the same principles. In the front line, however, the rapid restoration to duty of an acute neurosis was often possible to a skilful neurologist alone.

For the prevention of neuroses in the hospitalized the best method of all was that of the British Army Training Camp, to which every sick and wounded man in the later years of the war was sent before being returned to his unit. In these the ingenious yet simple method of restoring moral by collective influence was the idea of an unrevealed genius in the R.A.M.C. These camps followed the French example by keeping the patients in the advanced zone of the Army free from detrimental home influences. But when a whole country becomes liable to devastations by air attack, it may be asked whether this procedure will remain imperative.

These facts (presented in greater detail after the war in *The Military Surgeon*) should be of use in the present situation, perhaps even to the controversialists in these columns.—I am, etc.,

London, S.W.1, Sept. 25. TOM A. WILLIAMS.

SIR,—The article by Dr. Maurice B. Wright in your issue of September 16 (p. 615) is most timely and important and provides food for much thought and action. To a worker in neurological service during and after the last war the scheme appears useful and practicable. The most useful help for psychoneurotics is a person who understands their troubles, who enters their lives, and who by appeal can mobilize the scattered morale. Psychological casualties may be prevented or lessened by good food, adequate rest, sufficient security, and the inculcation of discipline, with the consequent raising of morale. The presence of a good A.R.P. service is an important factor.

At the aid post little treatment will be possible or expedient. The casualties will be retained until the "all clear" and then evacuated to the casualty clearing hospital. Here a physician experienced in such matters should see them, examine them, and sort them out into two groups. First, cases of little severity in people of fairly good morale may be retained for a week and then returned to their homes or to duty. This group will be a small one, but it includes those of excellent morale who have temporarily been put out of action by some sudden shock. About 5 per cent. of cases may be thus discharged. The second group of cases should be sent right away, far from the scenes which upset them, to some base hospital in the country. Here is security, good food, plenty of sleep, and sufficient interests to keep the patients' minds on brighter matters. Psychotherapy most suited to their needs is administered, preferably by a physician with psychotherapeutic experience. His colleagues should include a psychiatrist and a psycho-analyst for special cases. After six to eight weeks cases should be reviewed and regrouped. Patients in the larger group will have recovered to the extent that they may be transferred for further treatment at a convalescent camp or command depot. The smaller group will be transferred to special neurological hospitals.

At the command depot (for soldiers) or convalescent camp the time of the patient is more fully occupied by games, sports, and other exercises. In the case of soldiers training is gradually and sympathetically embodied and increased as groups improve. In six weeks it will be found that five out of six will be able to return to duty. Some do not benefit by this treatment and should be transferred to the special neurological hospitals.

At the special neurological hospitals the more severe cases arrive. These hospitals will be specially staffed. Longer and more individual treatment and longer time are requisite. Psychotherapy by several methods may be used, according to the judgment of the medical officers. It is here that the psycho-analyst school will have a chance to win its spurs. Its efforts will be cordially approved and its results noted with great interest. Physician psychotherapists (that rather old-fashioned group of clinicians to which I belong) will whole-heartedly assist in the great task of mending broken humanity.—I am, etc.,

Aberdeen, Sept. 18. A. W. HENDRY.

SIR,—Sir Arthur Hurst's letter in your issue of September 23 (p. 663) on the treatment of psychological casualties during war is particularly interesting to me.

I would like to point out the importance of making a correct diagnosis between functional and organic disorders. Medical boards have a tremendous responsibility, but how few of those who sit on these boards have any knowledge of electrical tests, or, if they have, employ them as an aid to diagnosis?

During my appointment as medical officer in charge of the department of physical medicine at the Special Surgical Neurological Hospital, Tooting, and afterwards at the Military Orthopaedic Hospital, Ducane Road, I tested many thousands of cases. These tests were an adjuvant to diagnoses already made, and gave an indication of the recovery of nerve injuries. I am sorry to say that in many cases functional was proved to be organic and organic functional. I particularly remember the case of a young soldier who had been shot in the neck, had produced a flail left arm from the shoulder, and had been told by "five medical doctors" (his words) that he would never use it again. He was discharged (*never to return to war and with the addition of a pension*). I italicize these words as I wish to point out the deep psychological effect this must have had on the soldier's mind. Moreover, he had already attuned himself into the future, with its advantages and disadvantages. Then I come along and find nothing abnormal with his electrical reactions, and carefully and tactfully have to get him to believe me instead of "five medical doctors." Luckily he was a keen cornet player, and was soon using his arm and did not have to go to Seale Hayne. No case of paresis, paralysis, etc., should be boarded without an electrical test having been done by an expert.

May I say how heartily I agree with the remarks of Mr. J. S. Kellett Smith (September 23, p. 664)—the effective fervent care of a well-qualified masseuse worketh marvels.—I am, etc.,

JOHN SAINSBURY, M.B., B.Ch.Oxon.

London, W.1, Sept. 27.

Psychological Treatment Centres

SIR,—It seems important at this stage of national stress that psychotherapeutists should put their house in order and pool their spirit for national use during the emergency. What happened in a war twenty years ago with military psychiatric casualties may not be the correct basis for understanding, assessing, or treating civilian neuroses in totalitarian war. Each psychotherapeutist should ere now have settled for his own practical usage basic ideas of psychic aetiology, and spectacular polemics about differential diagnosis or teleological therapy should be put aside for the more urgent need of medical organization to ensure the morale of the civilian population submitted to an unprecedented attack on its "nerves."

How are we as a profession to organize our resources so that we may be ready to meet the new demands upon our national protective functions? How are we to induce the potential psychotic to seek skilled advice or direction while he is still able and willing to do so? How are we to enlist quickly his social residue-values before he is a national debit and a source of psychic infection? Surely this is the problem rather than what "send-fool-further" (S.F.F.) label we shall put on him when he is already on the downhill road.

If sufferers avoid "mental hospitals," "voluntary certification," "psychiatric clinics," till they are beyond prophylactic help of static authorities, surely we need a more dynamic method of getting patients to come early without suggestion of stigma or misunderstanding of motive in our treatment direction.

This urgent demand is a by-product of our strange era and we need a new method of organization to deal with it. *There is at present no national system capable of tackling the problem.* The solution is clear. Establish centres of stability for reintegration of disturbed personality states; establish them to be in time to be working when they will be needed; establish them in a way to gain popular confidence; and, in order that prevention may have precedence of cure, establish them now.

The name "psychological treatment centre" (P.T.C.) is comprehensive enough to cover its primary purpose of being a casualty clearing station for all the multiplicity of minor as distinct from major psychiatric casualties; it is euphemistic enough to assist the doubtful and secretly phobic to come freely to get aid, and it is co-ordinative enough to allow room for all psychotherapeutists who desire to so serve, in part or in whole, for "the duration" and thereafter. If the local M.O.H., as already the rallying-point of local medical practitioners, be requested or empowered to choose or appoint men and women in his district who know local psychology, the establishment of "psychological treatment centres" all over the country could take place quickly and effectively. We have no need to quarrel about methods: only practical application in the present emergency could test the rival claims of various "schools." We need workers in this new sphere. Psychotherapeutists cannot be made in a day, nor can they be produced by a magician's wand in times of peril. They already exist. All they need is to be used, to be organized, and to be got ready for national service. I issue a call to all psychotherapeutists in this country: *Now* is the time to enlist your services for defence of the nation's nerves.—I am, etc.,

A. C. D. TELFER, M.B., B.S.

Walthamstow, September 29.

Organization of Aid Posts

SIR,—May I be allowed to comment on one important aspect of Dr. C. Seeley's interesting article on the organization of the emergency medical services in the *Journal* of September 30 (p. 697)? Concerning first-aid parties he states that "members of the parties must exercise discrimination in the initial disposal of cases, etc.," and I am officially informed that the ambulance men are expected to decide which cases are to go to hospital and which to the first-aid posts. (I did hear, at an official gathering, an even simpler rule—namely, that all ambulance-borne cases were to go to hospitals, all "sitting-up" cases to first-aid posts.) Now where the ambulance men have had some practical experience in air-raid work this method may work fairly well, also in cases where the distance to the casualty receiving hospital is short. But where the casualty receiving hospital is a long way away, and where the ambulance men have not had any practical experience of this type of case—that is, roughly in rural and semi-rural areas—it seems to me unjustifiable to put such a heavy responsibility on the ambulance-trained personnel unless it is quite impossible for them to obtain the opinion of a doctor.

Dr. Seeley states later on that "aid posts have been sited at hospitals . . . or in buildings close to hospitals." In Cheshire, and I believe generally throughout the country, first-aid posts planned at the local cottage hospitals have all been moved away; I think quite rightly. In these circumstances over wide areas ambulances must often pass by or close to an aid post before they can get to the casualty receiving hospital. Where such conditions obtain it would seem much more reasonable for such cases to call at the aid post and be seen by the doctor there, if possible, without being removed from the vehicle, and the doctor then can decide whether the case should go straight to hospital, whether it requires immediate treatment for pain or shock at the first-aid post, or otherwise give directions and remove responsibility from the willing but less well-trained first-aid parties. Colonel E. M. Cowell (April 29, p. 883) has stressed the importance of the immediate and preventive treatment of shock, and the excellent instructions for first-aid posts (E.M.S./Gen/245) issued on the outbreak of war gives as the second of the functions of such posts "to arrest haemorrhage, relieve pain, and so prepare those casualties who may be found to require institutional treatment that they can be transferred to the casualty (receiving) hospital with the least possible harm—that is, by having taken steps to prevent any immediate deterioration."

Whether such steps should be taken immediately or whether they can be safely left till the case can reach hospital is often a matter requiring much judgment, and certainly a skill beyond that of the usual ambulance trainee. Many doctors in charge of first-aid posts have had war training which should fit them admirably to discharge this onerous duty. It seems a pity to prevent the civilians who may be injured obtaining all the help they can from the doctors on the spot by giving positive directions to the ambulance men to do something for which most of them are quite unfitted. It would seem much wiser to give a general direction that ambulance men may be allowed to discharge this function, and leave to those responsible in each locality the duty of making the most satisfactory arrangements they can in their particular circumstances.—I am, etc.,

Winsford, Cheshire, Oct. 2. W. N. LEAK.

Anaesthesia in War Time

SIR,—Concerned as this subject is almost entirely with the surgery of wounds, it cannot be divorced from surrounding conditions in which operations have to be done one after the other in quick succession and without the deliberate preparation and attention to perfected details that pertain in peace-time surgery. In the field there will be three chief categories of treatment:

1. The urgent abdominal and cranial surgery done by special surgical teams at the front.
2. The less urgent cases dealt with in casualty clearing stations.
3. The cases done in the general and stationary hospitals at the base which cannot wait over the time of transport to England.

In No. 1 the anaesthesia is in the hands of a special member of the team who will as a rule be selected from anaesthetic specialists. In cases of torn intestines or spleen, with abdominal haemorrhage, or in cases of head wounds the patients are often *in extremis* and the surgeons require as skilled anaesthesia as they can get. But in all the many casualty, stationary, and general hospitals there will be more anaesthetists required than there are specialists available. After a big action ambulance trains arrive with several hundred cases that require major operation.

By the refinements of modern anaesthetic practice, complex machinery has been introduced whereby ethylene, cyclopropane, and carbon dioxide as well as nitrous oxide and oxygen, and ether if required, can be administered. But these complicated contrivances are very far from being fool-proof—that is, beyond the management of those who are without constant experience of them. And when such contrivances go wrong they become dangerous and worse than useless. These considerations must be kept well in the forefront when the subject of military anaesthesia in active service on a wholesale scale has to be faced, or, in other words, *in the field*. Peace-time anaesthetics are an insufficient basis; we must go back to the experience of the 1914–18 war. We shall be operating on men in their youthful prime, in sound physical state, a certain number in shell-shocked condition, but not cases of liver or cardiac disease or diabetes or tuberculosis as are met with in civil life.

Nitrous oxide is a splendid safe anaesthetic, but only for minor operations; in major surgery it requires an anaesthetic specialist. It can be ruled out for general war use. The vast majority of war operations are in the major class. In these days of high explosives even a small punctate wound may be found to have much torn tissue that requires free excision. Avertin and paraldehyde, given per rectum from thirty minutes to several hours before operation, are impossible. Nembutal given intravenously requires special skill and care. Evipan sodium and pentothal sodium are too transient. Spinal anaesthesia lies in the hands of those surgeons who feel competent to give it in certain cases. Endotracheal anaesthesia can be reserved for hospitals which specially deal with dental cases. It requires wide-bore endotracheal tubes, cylinders, bag, and face-piece for nitrous oxide.

What was the outcome of experience in the last war? Undoubtedly that the most practical, most easily administered, most frequently used, and most satisfactory anaesthesia was obtained by giving chloroform and ether. In many hospitals this was preceded by a hypodermic injection of morphine 1/4 grain and atropine. Any qualified man could give the anaesthetic. Shipway's apparatus was almost invariably used. Sometimes when a doctor was not available a nursing sister or an R.A.M.C. hospital orderly was employed and very soon learned to do it well. By Shipway's apparatus the time of induction of anaesthesia was shortened by chloroform, which could often produce analgesia before consciousness was lost. It required little practice to know when to switch over to the warmed ether, which then proceeded smoothly by the mere action of steady rhythmical compression of the rubber bulb. Premedication by hypodermic morphine helped considerably to lessen the quantity of anaesthetic required.

In the days following a big action most hospital theatres had to deal with a rapid succession of cases, one patient being no sooner removed than another was on the table, so that the more promptly the patient became unconscious the better for all concerned. Without access to mortality figures, one can safely say, speaking from actual experience, that deaths due solely to overdosage of chloroform and ether were an unknown factor. In the American war hospitals where they had a most marked national fear of chloroform it was noticeable that the American surgeons had to suffer delay and had more trouble in the maintenance of deep anaesthesia than was the case in British and French hospitals.

It would therefore become a great desideratum for any body or committee of anaesthetists who have to decide on the laying down of a scheme of war anaesthesia for general use to resolve to repeat the successful method employed in the last war and to make chloroform and ether (of known reliable brands) administered by Shipway's apparatus a component part of each and every surgical outfit.—I am, etc.,

September 27. G. D. G.

Emergency Treatment of Burns

Sir,—An official statement quoted in your *Supplement* of September 2 (p. 167) advises the use of picric acid. When this is put into practice a large number of cases of eczematous and blistering dermatitis from intolerance is sure to be seen. I know these plans have been worked out with careful consideration for the many factors involved, but I must call attention to the fact that a watery solution of gentian-violet is cheap, effective, non-irritating, antiseptic, easy to use even by the veriest layman, has to a degree a tanning effect, and gives symptomatic relief in second degree burns as picric acid does not.

I do not know how accessible gentian-violet is in England; my source has been Merck's aniline-violet, bought by me in 1-oz. bottles of the crystals for about $0.40. One ounce of the crystals stirred in 3 quarts of water (which need not be boiled) makes the suitable 2 per cent. aqueous (not alcoholic) solution, to be swabbed over the burned skin. It should be put on so as to enter the blisters, beneath the caps of which it forms a coating over the denuded dermis, allays pain excellently, and keeps the skin from contamination with Gram-positive bacteria and fungi. It may be applied to large areas, in adults or infants, without fear of toxicity or the provocation of eczema—advantages over picric acid. In the emergency treatment of burns by local application gentian-violet has no superior, a fact which experience will surely bear out if it is put to the test. The solution does not deteriorate.

Gentian-violet stops the action of staphylococci, fungi, and many streptococci. The streptococci which are not responsive to gentian-violet do respond to sulphapyridine and to moist applications of 1:10,000 bichloride of mercury. Few skin infections occur which cannot be treated with prompt success by the use of gentian-violet, supplemented as indicated by wet packs of bichloride of mercury.—I am, etc.,

Kansas City, September 20. Richard L. Sutton, Jun.

X-ray Examination of Militiamen

Sir,—As one who advocates the periodic mass radiological examination of the "healthy" population as the only logical and worth-while method at present of detecting phthisis in its early and treatable stages, I could not but view with enthusiasm the opinion expressed by Dr. J. V. Sparks in the *Journal* (May 13, p. 1003, and September 23, p. 664) on the need for *x*-ray examination of the chest in militiamen. But the letter from Dr. J. E. Bannen (September 30, p. 702) has checked this enthusiasm and given me food for thought. For in it is introduced the term "arrested"—a clinical, nay, an administrative term that should be avoided by a radiologist at all costs—and there is advocated serial miniature *x*-ray photography, a method still on trial and considered as unreliable by several authorities. Radiological examination of militiamen would without doubt detect an appreciable percentage of early active tuberculous lesions that cannot even be suspected in the few minutes the examining medical officer is allowed to carry out the "complete" examination of the man, but it would also produce a much larger percentage of skiagrams, showing various apical shadows and exaggerated hilar and lung markings, which might lead to the unnecessary rejection of many men—these shadows taking the place with a vengeance of the added or altered sounds at the apices in the last war. Routine radiological examination of militiamen would raise a hornet's nest unless it was carried out by radiologists expert in chest radiography working in conjunction with an experienced tuberculosis physician or, better still, by tuberculosis physicians expert in the interpretation of chest skiagrams with such a radiologist available for consultation. The fact that in many quarters there is still some doubt as to the value of radiography in the diagnosis of phthisis and that discussions on the *relative* merits of physical and radiological examination in this connexion can still take place makes me wonder whether we have at our disposal the number of such trained people that would be required if the policy advocated by Dr. Sparks were adopted. Unless we have, it may be found that radiological examination of militiamen will prove for the military authorities (though not from the public health point of view) far from a blessing.—I am, etc.,

Staines, October 1. G. Gregory Kayne.

Evacuation

Sir,—The intolerable burden which has been placed on rural districts by the Government evacuation scheme cannot be sufficiently realized. As time goes on its effects will become more apparent.

Just at a time when one's nerves are somewhat on the stretch, when every household is worried, when husbands, sons, and relations are being called up to fight, when most of us have extra work to do—at that moment we are not asked but commanded to take evacuees into our houses. One will gladly admit that most of the evacuees are decent people, but even so, whatever rules may be laid down their entry into a private house means more work for the unfortunate housewife, who often is overworked already. In one's consulting room it is becoming increasingly common to see women whose health is being undermined by this worry and overwork.

In addition to those whom we may call the decent evacuees there is a sufficiently large minority of objectionable people to make the whole scheme a scandal and impracticable. I do not think it is using language any too strong to say that in many cases the scum of a town has been poured into a clean countryside with a most callous disregard for the consequences and apparently without the most elementary safeguards for the public health.

Is it not time to review the situation in the light of recent experience? The evacuees would fall roughly into three classes:

(1) Those who could remain in private billets where mutually agreeable.

(2) Those who would be more happy in empty houses, converted public buildings, etc.

(3) Those who require to be in a camp under some sort of discipline where they could be taught the rudiments of personal cleanliness, self-respect, and (incredible as it may seem) the use of a lavatory.

It should be possible to work out some plan whereby the present injustices to both sides are less acute, and in doing so I think our profession, which has an intimate knowledge of the actual living conditions of all classes, might collaborate with the less informed urban authorities.

It is essential that we should know whether the Government, having evacuated these people, is content to leave the country districts to struggle on as best they can or whether it is actively engaged in devising new measures to ameliorate the present unsatisfactory situation. There are limits to what people will stand, and in too many cases these limits have already been reached.—I am, etc.,

Melksham, Sept. 28. I. C. Keir, M.D.

Sir,—In your issue of September 9 (p. 573) you published a short notice of the meeting of journalists summoned by Mr. Herbert Morrison, leader of the L.C.C., on September 4 "to rejoice with him on the completion that day of the evacuation from London of some 650,000 persons." *Audi alteram partem.* The reception areas are not impressed with the efficiency of the L.C.C. The letter in the *Times* of to-day's date (September 29), signed "Dorothea Coke," is an emphatic contradiction of Mr. Morrison's complacency. It ends with the query, "When is the L.C.C. going to wake up to the muddle it has made and send its staff [of welfare workers] down to remedy the shameful conditions it spread through the country."

These are strong words, but in the opinion of many country dwellers entirely justifiable. The L.C.C. apparently took no precautions to avoid the dissemination of vermin, or, if it did, its methods were ineffective.—I am, etc.,

Basingstoke, Sept. 29. Hugh Thursfield.

Sir,—You seem to think that the evacuation system is working well. If you ask general practitioners who go into the homes you will find it is the most unfair system ever devised. No one can say why people in many cases much poorer than the parents should have their home life ruined when plenty of empty houses were at that time available or why parents should not pay their share.—I am, etc.,

Ashtead, Surrey, Sept. 27. C. H. G. Prance, M.R.C.S.

⁂ The annotation in our issue of September 9 appeared under the heading "A Successful Exodus," and tribute was paid in it to the highly efficient way in which the process of evacuation was conducted. We concluded by saying, "There remains to be told, when the time comes, the story of how well the reception areas have risen to their opportunity."—Ed., *B.M.J.*

Medical Students in War

Sir,—May a medical student be permitted to raise a point which arises out of your "Medical Notes in Parliament' of September 23 (p. 667)? Dr. Elliot's reply to Mr. Parker's question in the House of Commons, so far as it was concerned with medical students, seemed particularly irrelevant. He, Dr. Elliot, could not believe that medical students wished to profit by the circumstances of war. Certainly we have no wish to profit in any way, but many of us are finding that in the present circumstances our training and living expenses are costing us very much more than in peace-time. In some areas the cost is nearly doubled, while in many instances students, or their parents, are less able to afford the cost of their training than hitherto. We do not necessarily object to this "tradition of voluntary service," but regard as a most undesirable anomaly a situation where we are not allowed to take up any other form of work and compelled to pay twice as much for "voluntary" work in which we have no option.—I am, etc.,

Oxford, Oct. 1. R. B. Buzzard.

Particulate Nature and Size of Filterable Tumour Agent

Sir,—Although for several years I have been profoundly sceptical of the validity of methods employed to demonstrate the particulate nature and size of the agent of filterable tumours, so far I have refrained from active criticism. It was considered more profitable to confine one's attention to the positive constructive task of trying to show how the phenomena of filterable tumour transmission, and especially the tissue specificity, could be much better explained on the assumption that the causative agent was of a non-particulate chemical nature.[1] The treatment of the subject in the leading article in the *Journal* of September 25 (p. 651) renders it necessary to point out some considerations, of the nature already referred to, which indicate that on this ground alone there is another side to the question than that championed therein. The principal methods in use for the purpose in hand are three in number, based respectively on (1) Poiseuille's law; (2) Stokes's (not Stoke's, as some who have written extensively on the subject have it) formula; and (3) microscopical examination.

Poiseuille's law has reference to the estimation of the pore diameter of a "membrane" possessing, as pores, straight cylinders of uniform small size and of circular cross-section situated between and at right angles to the "membrane" surfaces. The walls of these cylinders, moreover, are rigid, non-elastic, and non-compressible. Further, the determination of the average pore size is arrived at in practice by the measurement of the flow of pure water through the "membrane." In assessing the value of this method as applied to the present problem one may disregard the fallacies that arise through deposition on the membrane surface and adsorption on its pores, and the fact that it is the average pore diameter that is determined. These are of minor importance in the present connexion; although it will be evident that the former eventuality would decrease and the latter, on account of the maximum pores (which give rise to an unappreciated but highly important source of error where the estimation of the size of particles is concerned), effectively increase permeability. A major source of fallacy, which appears to be unsurmountable, however, remains. It may be indicated by remarking that it is incomprehensible how this formula, based as it is on the passage of pure water through rigid-walled cylinders arranged in regular pattern, has been applied so extensively to the determination of the size of elastic compressible particles which are being forced in the process of ultra-filtration through the irregular interstices, which are possibly mere artefacts, of an elastic compressible membrane.

Stokes's law applies to the deposition under the force of gravity of small, smooth, spherical, solid particles of uniform and constant density and size in a liquid of certain density and well defined and constant viscosity. In the application of this law to the problem in hand one may leave out of consideration as relatively unimportant the difficulties that arise from the fact that centrifugal force, not gravity, is employed, with the result that the motion of the particles alters with their distance from the axis of rotation, from the existence of vibrational and convectional disturbance of the fluid under centrifugation, and from the impossibility of avoiding inaccuracies in sampling and in determining in the extracts and centrifugates the concentration of the agent of filterable tumours. This latter drawback is in strong contrast to the accuracy with which the concentration of, say, gold sol may be estimated. That these difficulties may or may not be overcome is a matter of little moment in the final issue, since they are wholly overshadowed by another of greater magnitude and importance, which will now be referred to.

In view of the fact that solid particles such as lyophobe sols can raise the already low viscosity of the continuous phase, water, only by small amounts, and this simply in proportion to the volume of solid matter present, and that on the other hand the presence of small amounts of lyophile sols, such as albumin, may increase the viscosity some hundred times, the varying amounts of albumin in the continuous phase of a tumour extract has very considerable significance in regard to its viscosity coefficient. Further, if the particulate view of the nature of the agent is assumed, we are dealing in tumour extracts not with small, smooth, spherical, solid particles of uniform and constant specific gravity but with rough particles of irregular shape which are quite definitely lyophile elastic and compressible, and therefore of varying and variable density and size. In Stokes's formula, $V=\frac{2r^2(S-S^1)g}{9\eta}$, V is the magnitude of the velocity of the particle, r of its radius, S of its specific gravity, S^1 of the specific gravity of the continuous phase, η of its viscosity coefficient, and g of the gravity constant. Here every quantity on the right side of the equation is subject to uncontrollable and indeterminable variations, a circumstance which places the utilization of the formula for the solution of the present problem entirely out of the question.

---

[1] *On Rous, Leucotic, and Allied Tumours, etc.* (London, Lewis, 1928); *Edin. Med. J.*, 1929, 36, 645; *J. Canc. Res.*, 1930, 14, 527; *British Medical Journal*, 1936, 2, 1334, and 1938, 1, 698; *Edin. Med. J.*, 1937, 44, 37.

Finally, ultra-filtration and ultra-centrifugation may in the extreme case, conceivably, at times remove the whole of the agent from a tumour extract. It is not, however, to be argued on this ground that the agent is particulate. The onus of proof that the agent in such a case has not been adsorbed on particulate organic matter, such as cell debris, etc., and so removed, rests on those who hold an opposite opinion. The finding by microscopical examination of particles on the surface of the retaining membrane or in the deposit on centrifugation is of no avail in settling the question, since microscopical examination, alone or assisted by staining methods, has proved incapable of determining the nature of these particles.—I am, etc.,

Aberdeen, September 26. J. P. MCGOWAN.

Routine Tuberculin Testing of Children

SIR,—The introduction of the tuberculin patch test with its simplicity, painlessness, and relative freedom from severe local or general reaction raises the question whether tuberculin testing should not be more generally applied among children attending for medical examination at welfare clinics and the like. Such testing might be expected to result in (1) the discovery of early cases of active tuberculosis in children; and (2) the discovery of unrecognized or inadequately treated cases of adult tuberculosis among the home contacts of tuberculin-positive children.

The Camberwell tuberculosis officer realized the possibility of such a scheme, and with the approval of the medical officer of health the Vollmer tuberculin patch test has been applied during the present year to 350 children, aged between 1 and 4 years, who had attended the five toddlers' consultation clinics in the borough of Camberwell. Eighteen positives have been discovered and these have been referred to hospital for further investigation, including a skiagram of the chest. Of these eighteen, three children have proved to be suffering from pulmonary tuberculosis with sufficient evidence of activity to warrant immediate institutional treatment. The following case is illustrative:

A child aged 1 year was brought to the clinic for her annual examination. The mother said the child was quite well. Examination showed a sturdy vigorous baby of normal weight. The patch test was positive and there was a history of contact. The skiagram showed extensive lung infiltration, and activity was confirmed by a much raised sedimentation rate. After six months' treatment in a sanatorium the child is now progressing well.

In half the positives there was a clear history of contact, although in some of these the adult in question was not receiving treatment, and the occasion was used to exert pressure towards this end. In the remaining nine positives where there was no history of contact a special attempt to discover one by examining home contacts has been made by the tuberculosis officer. So far no new case of adult tuberculosis has been discovered in this way, but in one case such an investigation revealed that infection had occurred from a case of tuberculosis unknown to the child's parents. The case illustrates how mutually advantageous close co-operation between the toddlers' clinics and the tuberculosis dispensary can be:

A 2-year-old child was brought to the clinic for her annual examination. For some months she had not been as bright as usual, and had recently developed a slight cough. Physical signs were indefinite. The patch test was positive, but questioning of the mother failed to reveal any definite story of contact. A skiagram showed opacity of the right upper lobe, and she was sent to a convalescent home as a case of epituberculosis. Inquiries by the tuberculosis officer now revealed that the mother went to work during the day and left the child with a woman. A month previously the husband of the latter had died, but she had not disclosed to the child's parents that the cause of his death was tuberculosis, although frequent contact with the child had occurred. By also failing to disclose to the tuberculosis officer the child's presence in her house, the child had escaped the examination to which other members of the household had been subjected after the man's death.

The discovery within eight months of three cases of active tuberculosis in children, in two of which there were neither symptoms nor signs such as could have allowed the diagnosis to be made at this stage without the evidence afforded by the patch test, is surely striking. Might not the more general introduction of tuberculin testing of young children be a worth-while step forward in the campaign against tuberculosis?—I am, etc.,

London, N.W.1, October 7. DOUGLAS GAIRDNER.

The "Iron Lung" in Treatment of Scoliosis

SIR,—I am very grateful to Mr. S. Alan S. Malkin (*Journal*, September 30, p. 702) for trying out this method of treatment which I suggested in my letter in the *Journal* of February 25 (p. 416). His statement that, in selected cases, improvement has been very marked is particularly welcome. Of the two hospitals with which I am connected, at one the apparatus has not yet been fully assembled, while at the other it has been in constant use for the treatment of paralytic cases. When hospital conditions become more stabilized I shall endeavour to give the method a complete and prolonged trial. Meanwhile, I strongly endorse Mr. Malkin's opinion that this line of treatment should be tried in other centres.—I am, etc.,

Hove, Sept. 30. J. M. TURNER, F.R.C.S.

The Services

DEATHS IN THE SERVICES

Surgeon Commander EDWIN FOLLIOTT, R.N. (ret.), died at Salisbury on September 21. He was educated at St. Bartholomew's Hospital, and took the M.R.C.S., L.R.C.P. in 1896. After filling the post of assistant house-surgeon at Shrewsbury Infirmary he entered the Royal Navy, attained the rank of surgeon commander on May 25, 1911, and retired soon after the end of the war of 1914–18, through which he served, receiving the medals. He then specialized in tuberculosis work, serving as clinical assistant to the Plymouth Tuberculosis Dispensary and as assistant tuberculosis physician at Cardiff, after which he became tuberculosis physician to the King Edward VII Welsh National Memorial Association, and tuberculosis consultant to the Aberdare, Merthyr, and Mountain Ash general hospitals, and to Merthyr Infirmary, and medical officer of Pontsarn Tuberculosis Hospital.

Colonel JAMES MEEK, C.B., late R.A.M.C., died at Belfast on July 5, aged 77. He was born on November 20, 1861, and was educated at Queen's College, Belfast, where he gained an entrance scholarship. He graduated M.D. and M.Ch. of the Royal University of Ireland with honours, and gained the first Peel exhibition; he subsequently took the D.P.H. of the London Colleges in 1905. Entering the Army as surgeon on May 30, 1885, he attained the rank of Colonel on August 3, 1914, and retired on November 20, 1918. He served in the Sikkim War of 1888, gaining the frontier medal with a clasp; in China in 1900, on the hospital ship *Maine* (medal); in South Africa in 1900–2, first on the hospital ship *Maine* and later in operations in the Orange River Colony and in the Transvaal (mentioned in dispatches, *London Gazette* of June 17, 1902, Queen's medal with three clasps); and in the war of 1914–18, when he was mentioned in dispatches in the *London Gazette* of February 17 and June 22, 1915, in which year he received the C.B.

No. 37

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended September 16, 1939.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland. Median values for the last 9 years for (a) and (b).

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1939					1938 (Corresponding Week)

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

There has been little change in the incidence of the principal infectious diseases during the last week or two. From many quarters there have been reports of an increase in the incidence of diphtheria and scarlet fever in rural districts due to the reception of susceptible subjects, but these do not appear to have been outbreaks of any magnitude. Some local authorities in these areas have expressed doubt as to the adequacy of the isolation hospital accommodation at their disposal, and are making plans to enlarge it. There has been little change in the last few weeks in the incidence of enteric fever and cerebrospinal fever, both of which tend to increase under war conditions, and the figures for acute poliomyelitis remain low—from a third to half of those recorded last year.

Owing to delays incidental to war conditions in collecting the weekly returns from certain districts the epidemiological table was omitted last week and appears in the present issue. It is hoped that as communication improves it will be possible to revert to the normal procedure. The figures for the median values for the preceding nine years are no longer available, as the data are not comparable in all material respects, and the column is therefore being discontinued for the time being.

Obituary

We regret to announce the death of Dr. **THOMAS JOHNSTONE**, formerly of Ilkley and Harrogate, who died on September 17 at the age of 86. Dr. Johnstone qualified M.B., C.M., and L.M. in 1874 and proceeded to the M.D.Ed. in 1877. In 1887 he took his M.R.C.P.Lond. After qualification Dr. Johnstone settled at Ilkley, where he remained for nearly forty years, and was appointed medical officer of health just over fifty years ago. He was also medical officer to the Ilkley Hospital and Convalescent Home and to the Semon Home. He acted as consulting physician to Ilkley Coronation Hospital, was physician to the Ben Rhydding Hydropathic Establishment, and senior resident physician to the Crichton Royal Mental Hospital, Dumfries. Subsequently he moved to Harrogate, and during the last war was engaged in work at the Ripon Dispersal Camp. A man of diverse interests, he was a director of one or two business concerns and was an energetic Freemason. Dr. Johnstone revised and edited a translation of Kraepelin's *Lectures on Clinical Psychiatry*. Among his contributions to medical literature he wrote on the clinical measurement of fatigue and on dementia praecox. He was a member of the British Medical Association for sixty-five years.

The sudden death on September 17 of Dr. **LAURENCE JOHN HONEYWILL** from septicaemia and pyaemia at the early age of 27 has come as a great shock to his friends. He was one of the most brilliant students of recent years at University College Hospital, and there was every reason to anticipate that he would have a very distinguished surgical career. Honeywill received his medical education at University College Hospital, entering the medical school there in 1933 with a Goldsmid Exhibition. He later shared the Magrath Clinical Scholarship and won the Atchison Scholarship awarded to the student "who within a period of three years reckoned from the date of his entry to the school has shown the best work and greatest proficiency as a student of the medical school and hospital." He qualified M.R.C.S., L.R.C.P. in 1936, in 1937 obtained the F.R.C.S.Eng., and a year later the M.B., B.S.Lond., with the University gold medal and distinction in surgery and obstetrics. After qualifying he was house-surgeon, house-physician, and casualty surgical officer at University College Hospital. He leaves a widow and an infant daughter.

Dr. **CHARLES COTTON**, F.R.C.P.Ed., a well-known archaeologist, died on September 28 at The Precincts, Canterbury, aged 83. Born at Twickenham on February 7, 1856, he studied medicine at St. George's Hospital, and qualified M.R.C.S.Eng. and L.R.C.P.Ed. in 1879, afterwards proceeding to the Membership and the Fellowship of the Edinburgh College. In 1895 he was appointed physician to the Ramsgate General Hospital and Seamen's Infirmary, and in 1910 became County Director of Voluntary Aid Detachments and Commissioner under the St. John Ambulance Brigade for the Canterbury area. Dr. Cotton was a prominent member of the Kent Archaeological Society, and wrote learned papers for the *Transactions of the Royal Historical Society* and *Archaeologia Cantiana*. His writings included "A Kentish Cartulary of the Order of St. John of Jerusalem."

The untimely death of Dr. **JOHN GRAY**, reader in pathology at the British Postgraduate Medical School, will be felt keenly, not only by the many pathologists who knew and appreciated his work but also by a wide circle of friends in London, Edinburgh, and Aberdeen. Gray was educated in Edinburgh, and, like so many of his generation, went straight from school to war service. At the end of the war he began to study medicine at Edinburgh University, where he had a brilliant career. After graduating M.B., Ch.B. with honours in 1923, he was appointed part-time assistant in the anatomy department, and engaged in research on the embryology of the pituitary gland. There followed a period as house-physician at Edinburgh Royal Infirmary before he was appointed lecturer in morbid anatomy in the University of Aberdeen, a post he held with distinction for nine years from 1925 to 1934. It was then that Gray was at his best, for almost all the time he was in London he was a sick man. In Aberdeen he carried out important investigations on nephritis. His first paper on this subject was accepted for the M.D. of Edinburgh University, and was awarded a gold medal. Subsequently he carried this work further and expanded it into a Special Report (No. 178) for the Medical Research Council. Shortly after the publication of this authoritative treatise Gray went to London and joined the staff of the British Postgraduate Medical School as reader in pathology. It seemed in every way an ideal appointment, but his health, never robust, broke down completely, and for the last few years Gray was a semi-invalid. No one who had the privilege of working with him in this period will forget his unfailing cheerfulness under increasing difficulties. A brilliant pathologist, Gray hid his wide learning and experience under a shy, even diffident, manner; this in itself was typical of the man—kind, sincere, and modest to a fault. He will be greatly missed.

Medical News

The Harben Lectures for 1939 of the Royal Institute of Public Health and Hygiene on "The Physiological and Economic Basis of Nutrition" will be delivered by Sir John Boyd Orr, F.R.S., at 28, Portland Place, W., on Monday, Tuesday, and Wednesday, October 16, 17, and 18, at 3 p.m. In the first lecture Sir John Orr will speak on dietary standards, in the second on assessment of state of nutrition, and in the third on the public health, agricultural, and economic aspects of the nutrition problem. Admission to the lectures is free, and application for seats should be made to the secretary at 28, Portland Place, W.1.

A meeting of the Royal Society of Tropical Medicine and Hygiene will be held at 26, Portland Place, W., on Thursday, October 19, at 4.30 p.m., when Sir Rickard Christophers, F.R.S., will deliver his presidential address on "Malaria in War."

A series of ten lectures to clergy and ministers on psychological problems arising out of war conditions, in particular air raids, is being given on Fridays at 11 a.m. in the Milton Hall, Manchester. It has been arranged by the Manchester Branch of the National Council for Pastoral and Medical Co-operation.

The eighth Pan-American Congress of the Child will be held at San José, capital of Costa Rica, from October 12 to 19. The congress will be divided into six sections devoted respectively to medical paediatrics, surgical paediatrics, infantile hygiene and eugenics, education, social assistance, and legislation and sociology.

The thirty-second Italian Congress of Dermatology and Syphiligraphy will be held at Bologna from October 7 to 12, when a bust of the celebrated Professor Domenico Majocchi of Bologna will be unveiled. The chief subjects for discussion are inguinal lymphogranulomatosis and tuberculosis of the skin.

Owing to the war there will be no meetings of the Harveian Society of London until further notice.

The Central Hospital Supply Service of the Red Cross and St. John, the department responsible for organizing hospital supplies, has moved from 41, Lowndes Square, London, S.W., to 2, Lowndes Street.

Under war-time arrangements pre-clinical students of London medical schools are located temporarily as follows: St. Bartholomew's and the London Hospital at Cambridge; Charing Cross, St. George's, King's College, and Westminster at Glasgow University; Guy's at Sherwood Park, Tunbridge Wells; St. Mary's at Manchester University; Middlesex at Bristol University; Royal Free at St. Andrews and Aberdeen Universities; St. Thomas's at Oxford; and male students of University College at Aberystwyth (University of Wales). Students in their clinical years have for the most part been distributed over the ten sectors whose apices are at their own teaching hospitals. The administrative offices of the University of London are now at the Royal Holloway College, Englefield Green, Surrey.

At a meeting of the General Board of the Westminster Hospital last week the measures taken in accordance with the Ministry of Health scheme for emergency medical services were reported. While the Ministry had agreed to pay the cost of reserving 200 casualty beds, the income of the hospital, at a time when it had just entered into occupation of new buildings, had been seriously affected. It had been necessary to make the hospital, nurses' home, and medical school light-proof, and the cost of this alone, amounting to over £3,000, fell upon the general funds of the hospital. The ninety-three beds reserved for civilian sick were being rapidly filled up. The governors agreed that these should be increased by thirty, and that twenty-four more should be reserved for private patients.

The president and honorary secretary announce that the condition of war prevents the Ligue Internationale Contre le Rhumatisme from continuing its activities. The bureau at Amsterdam will be closed, and this will discharge council members, representatives, substitute representatives, editors, and members of the Ligue Internationale from their rights and duties.

Arrangements for the removal by stages of 35,000 additional school children from the evacuation areas in England have now been authorized by the Ministry of Health. In some districts the movement has started this week. These children were registered by their parents when, following completion of the main evacuation at the beginning of September, the Government decided to afford a further opportunity for evacuation of unaccompanied children. As billets become ready and transport is arranged, parties will be dispatched according to arrangements made between the evacuating area and the corresponding receiving area under the general direction of the Ministry of Health and the regional staffs. All the children will be medically inspected.

The July issue of the *Bulletin of the History of Medicine* is devoted to the transactions of the fifteenth annual meeting of the American Association of the History of Medicine held at Atlantic City, New Jersey, on April 20 and May 1, 1939.

The appeal of the Belgian Red Cross to athletic and philanthropic societies for blood donors aged from 20 to 60 has met with a gratifying response. There are at present fourteen centres for blood transfusion in Belgium.

Universities and Colleges

UNIVERSITY OF OXFORD

No serious reduction is anticipated in the numbers of medical students, as the age limit is 20, and not 18, and any student with two terms' anatomy and physiology is reserved. Dr. K. J. Franklin is deputizing as Dean of the Medical School for Dr. B. G. Macgraith, and Dr. A. M. Cooke is Clinical Sub-Dean; Dr. Cooke is also Assistant to the Regius Professor of Medicine. Pre-clinical students from St. Thomas's Hospital have moved to Oxford, and to conform with the arrangements usual at St. Thomas's plans have been made for a ten-weeks instead of an eight-weeks term this Michaelmas. Oxford medical students began work on October 2, two weeks before the rest of the University. Courses will conform so far as possible to the normal; but there must be some adaptation to the emergency circumstances. In view of the disturbed arrangements in London clinical schools, the University Department of Medicine is offering to its own students only a complete second B.M. course in the Radcliffe Infirmary and associated hospitals, provided the war lasts that long. The initial ten-weeks course (general pathology and bacteriology and an introduction to clinical work) began on October 2. The Department is also offering facilities, but not set courses, to a limited number of its own students whose clinical courses, begun elsewhere, have been interrupted by the war. Applicants should write to the Clinical Sub-Dean, the Radcliffe Infirmary, Oxford, stating what they have already done, what they still have to do, and when they propose to sit for the Final B.M. examination. By a recent decree those students who have passed all the examinations for the first B.M. are deemed to have passed all the examinations requisite for the degree of B.A.—that is, they will not, as most of them normally do, interpose a year of study for the Final Honour School of Animal Physiology between the first and second B.M. courses. At the moment the arrangements for the 1939 B.M. examinations stand, but there may be changes in 1940. The first B.M. examination begins on December 4, and the second B.M. examination on December 6, 1939. The D.O. course and examination are suspended for the academic year 1939–40. The address of the Dean of the Medical School remains as before —namely, Department of Medicine, the Museum, Oxford.

UNIVERSITY OF LONDON

London School of Hygiene and Tropical Medicine

It has been decided that the office and certain departments of the London School of Hygiene and Tropical Medicine shall remain for the present at the school building in Keppel Street, Gower Street, W.C. Although courses normally lasting an academic year have necessarily had to be discontinued for the time being, it is hoped in the near future to provide short courses of instruction in tropical medicine and hygiene. The school library will be open between the hours of 10 a.m. and 5 p.m. (Saturdays 10 a.m. and 12 noon), and the librarian will be glad to answer inquiries by post or telephone.

UNIVERSITY OF GLASGOW

At a graduation ceremony held on September 27 the following medical degrees were conferred:

M.B., Ch.B.—*A. W. Kay, *D. Struthers, *G. C. McKinlay, †A. Muir, †A. Allison, †W. D. Buchanan, †H. B. Young, † C. M. Steven, †W. Blair, †H. N. Munro, †K. R. Urquhart, ‡A. H. Lauder, †J. Milne, † Alexina MacL. Paterson, †D. G. Wright, †Isabella M. Kerr, G. F. Allan, G. R. Anderson, W. Anderson, B. Andrew, Janey C. A. Arnott, J. Ballantine, H. Barrowman, I. S. Bergius, A. Berkovitch, J. Black, Catherine I. Blyth, Enid E. Brackenbury, A. Brown, Marrion A. McK. Brown, O. T. Brown, W. Brown, Janet M. Bruce, Margaret L. Bryson, A. M. Buchanan, J. R. F. Buchanan, M. Buchanan, Helen D. Burns, Margaret Callaghan, H. C. Campbell, J. L. Campbell, W. R. S. Campbell, D. Canning, Agnes E. D. Cathcart, M. R. Chassels, S. Childs, S. Citron, J. Corbet, R. L. Coulter, L. Couper, J. M. Crawford, Muriel C. H. Cunningham, J. P. Currie, R. G. Dalziel, Barbara M. Davidson, Isabel Davidson, P. W. McL. Davidson, A. S. Dawson, A. Dick, J. Donaldson, J. L. Douglas, H. Duff, H. G. Easton, G. M. Edington, R. S. Edington, H. Fairlie, J. Ferrier, R. Finlay, J. W. Fleming, J. U. Forbes, J. A. Fraser, J. F. M. Frew, Marion S. Gardner, Marjory A. Garrey, W. M. Gibson, J. G. Gillan, Janet B. Grant, S. Haase, H. L. Hart, Mary B. Howat, T. K. Howat, J. F. K. Hutton, Jesse D. Johnston, W. C. Johnston, L. G. Jubb, G. M. Kesson, A. W. Lees, G. Leslie, Milicent H. S. Leslie, Brenda E. Linck, R. Livingstone, W. P. D. Logan, J. Loudon, Jean M. McArthur, J. J. McCall, A. I. McCallum, J. McComb, E. L. F. McConnachie, J. S. McCrae, A. C. Macdonald, I. A. Macdonald, T. L. Macdonald, J. L. MacDougall, H. M. Marfarlane, I. W. Macfarlane, I. D. Macfie, P. G. McGrath, W. Q. McIntyre, A. McN. McKelvie,

W. B. McKenna, W. R. Mackie, C. M. McLean, A. MacLellan, I. McLennan, J. A. MacLeod, R. G. MacLeod, Helen McC. McNeish, P. F. Maguire, S. S. Mair, K. C. Matheson, H. J. B. Miller, R. I. Mitchell, R. Montgomery, Greer C. Murray, Margaret K. Murray, R. Murray, J. C. Mustardé, R. S. Patrick, R. Paul, D. Raeside, E. Rentoul, W. D. Richardson, Mary McC. Richmond, W. D. Ritchie, R. B. G. Robertson, N. O. Rodger, J. Rogers, A. M. Roy, D. Salamon, J. Scobbie, Dorothea H. Graham-Service, F. Shaw, J. Simpson, J. C. Simson, J. G. Smith, Jean McC. Smith, P. Sommerville, W. Steele, Elizabeth M. Stephen, Mary Sullivan, J. D. Thomson, Janet Todd, J. W. Totten, J. A. Urquhart, R. Waddell, F. M. Wainman, A. P. Walker, R. T. B. Watson, J. Weir, W. P. Weir, Margaret E. Wells, Janet C. Willock, Margaret P. Wilson, R. M. Wink, G. M. Wood, Marion T. Wright, Eileen S. M. Wybar, A. K. Young.

* With honours. † With commendation.

Andrew Watt Kay gained the Brunton Memorial Prize, awarded to the most distinguished graduate in medicine for the year 1939.

The West of Scotland R.A.M.C. Memorial Prize was awarded to Andrew Watt Kay as the candidate with the highest aggregate marks in surgery, medicine, and midwifery in the Final M.B., Ch.B., examinations held during 1939.

The Macewen Medal in Surgery was awarded to David Struthers as the candidate who obtained the highest aggregate marks in surgery in the Final M.B., Ch.B. examinations held during 1939.

The Stockman Medal was awarded to Hamish N. Munro as the candidate who obtained the highest aggregate of marks in the professional examinations in materia medica and therapeutics and medicine (written, oral, and clinical), excluding paediatrics, in 1939.

The John W. Weir Prize was awarded to Andrew Muir as the candidate who obtained the highest aggregate number of marks in midwifery and diseases of women in the final degree examinations in medicine held in 1939.

GUY'S HOSPITAL DENTAL SCHOOL

It is proposed to reopen the Guy's Hospital Dental School on November 1 at a large clinic one and a half miles distant from Tunbridge Wells. Provision is being made for students in all stages of their course, including pre-medical studies. The clinic is situated in the neighbourhood of the base hospital of the Guy's Sector. There will be a subsidiary clinic in which conservative work, extractions, and prosthetic work will be carried out actually in Tunbridge Wells. Accommodation will be provided in the School for some of the students. Further particulars may be obtained from the Sub-Dean, Guy's Hospital Dental School, London Bridge, S.E.1.

Medical Notes in Parliament

Mr. CHAMBERLAIN made a statement in the House of Commons on October 3 about the war. He said that if peace proposals were made the British Government would examine and test them. No such proposals had yet been received.

The Finance Bill was read a second time in the House of Commons on October 2. Replying to the debate Sir JOHN SIMON mentioned that cosmetics had been put on the list of prohibited imports. During the preliminary debate on the Budget Resolutions Sir ARNOLD WILSON said on September 28 that many would welcome a tax on medicines, even including healing medicines, provided a small sum were earmarked for the medical health services of the nation. Sir FRANCIS FREMANTLE, speaking on September 29 on a proposal to reduce the sugar duty, said enormous damage was done to the teeth of children by confectionery, and that dental decay was at the root of rheumatism. The motion to reduce the duty was defeated. Mr. BOOTHBY, speaking on the Finance Bill on October 2, referred to the case of a Harley Street physician, with a very high rent, who had been making sums of anything from £5,000 to £10,000 a year, and now found himself on Government work in a hospital at a salary of £400 a year; yet he had to pay tax on the very large sums he had earned in recent years. Sir JOHN SIMON intervened and said: "What my hon. friend is saying is not in accordance with the provisions of the Bill or what I said in my speech. I am so conscious of cases of the sort that he has quoted that I explained in my Budget speech that instead of calling upon such a taxpayer to pay in respect of those thousands of pounds earned in past years he would be entitled to substitute his actual earnings of this year. That is an enormous alleviation."

The Parliamentary Medical Committee met at the House of Commons on September 28, with Sir Francis Fremantle in the chair, and will continue regular meetings during the war. Sir Francis Fremantle, as representative on the Central Emergency Committee of the British Medical Association, reported on the present position of the profession. The Committee discussed the under-employment of medical men in certain public services, the establishment of military hospitals in the United Kingdom, the interchange of patients between civil and military hospitals, and the medical treatment of the civil population. It also considered the admittance of patients to hospitals, their evacuation to more distant hospitals, and evacuation of patients to their homes. Petrol rationing to medical men and the employment of radium were discussed. Subsequently Sir Francis Fremantle and Dr. Howitt went as a deputation to Dr. Elliot, put forward considerations on several subjects named above, and found that he is active to rectify defects.

Hospital and Medical Services for Civilians

On September 26 Mr. SORENSEN asked the Minister of Health whether he was aware of the acute suffering and hardship caused by the removal of certain patients from hospitals to their homes, by the refusal of beds to patients needing special treatment, and by the relative scarcity of medical services in reception areas, and also of the number of doctors, nurses, and other medical staff on duty but performing no immediate service in hospitals allocated to deal with air raid victims. Miss HORSBRUGH said that the Minister was aware that difficulties and hardships had inevitably arisen from the far-reaching steps which were of necessity taken to deal with the possibility of large numbers of casualties from air raids. Numerous steps had been taken to enable the best possible use to be made of the hospital accommodation and medical and nursing personnel at present available. Arrangements had been made to release for part-time service in private practice a number of doctors at present employed in the Emergency Medical Service. All possible publicity had been given to several announcements that patients whose condition required hospital treatment, whether in-patient or out-patient, should certainly receive it. The Minister was continuing to keep the situation closely under review.

Health of Evacuated Children in Scotland

On September 26 Mr. HENDERSON STEWART asked the Secretary for Scotland how, in view of the large sums spent on health services in the cities of Scotland and the repeated assurances that these services were adequate and efficient, he accounted for the serious bodily condition of so many of the persons recently evacuated; and whether he would order an immediate inquiry into the health services of the cities of Scotland. Mr. COLVILLE said there had been a tendency to exaggerate the position, but that a proportion of the evacuated children were suffering from skin diseases or were in a verminous condition. He did not consider that an inquiry such as Mr. Henderson Stewart suggested would serve a useful purpose in present circumstances. He had arranged that the local authorities of sending areas would make a thorough medical inspection and give whatever treatment was necessary before any further children were evacuated. The evacuation took place in conditions of urgency, at a time when the supervision of the children was curtailed because of school holidays.

Care of Expectant Mothers in Reception Areas

Dr. ELLIOT stated on September 28 that as normal public health services included organized visiting of expectant mothers, he was taking steps to ensure that such services were available in reception areas for evacuated women as well as for the ordinary population. Steps for augmenting health visiting staff were primarily a matter for the welfare authorities in the different areas to decide upon. He would shortly issue a circular giving advice to welfare authorities on this and other matters relating to the health of evacuees. He had no particulars showing to what extent health visiting staff had been transferred from evacuated to reception areas. An extra allowance to the householder for undertaking the additional responsibilities of attending upon an expectant mother during confinement was applicable in cases where, by agreement with the householder, arrangements were made for the confinement to take place in the billet. The usual arrangements were for the confinement to take place in a maternity hospital or maternity home. The availability of these arrangements should obviate any difficulty in cases where a householder who was otherwise willing felt unable to provide lodging and attendance for the mother for the payment of 10s. a week.

Patients evacuated from Hospitals

Miss Rathbone asked on September 29 whether any systematic review had been or would be made through the hospital or medical authorities or otherwise of all the patients evacuated from hospitals to their homes at the beginning of the war for the purpose of ascertaining whether they were receiving adequate medical and nursing attention. Dr. Elliot in reply said all hospitals had been instructed to provide in-patient treatment for all in need of it. If the medical advisers of patients requiring hospital treatment gave a certificate to this effect the patients should be able to obtain admission to hospital, whether cases evacuated from hospitals to their homes at the beginning of the war or fresh cases. He did not think it necessary to call for a special review of the cases sent home by the hospital authorities at the beginning of the war.

Dr. Elliot, in reply to further questions, said all these cases were covered by domiciliary services, or through the insurance schemes, or through the out-patient department of the hospitals. If any almoner, district nurse, or anybody else came into contact with any case which required hospital treatment they should refer the matter to the patient's medical attendant, or, if the patient had no medical attendant, to the public assistance authority. Only on the certificate of a medical practitioner would a patient be admitted to hospital. In that way the population was fully covered.

Evacuation Problems

Replying, on September 29, to a question by Sir Ralph Glyn on evacuation, Dr. Elliot said the Ministry of Health, both at headquarters and through the regional organizations in the country, constantly sought to adjust the difficulties and hardships to which so large a movement, carried through of necessity in so short a time, inevitably gave rise. Full account was taken of the many reports, official and unofficial, from the receiving areas. Improvements and developments, and revision of policy where called for, were indicated in communications to the local authorities, such as Circular 1871 recently issued. A circular on medical arrangements would shortly be sent out. Representations on the necessity for adequate medical examination of evacuated school children would receive full weight.

Supply of Inhalers for Lung Conditions.—Mr. Sorensen asked on September 26 whether the Government had considered the provision of an inhaler or apparatus for the immediate treatment of the lungs of sufferers from a gas attack, and whether its inclusion in official air raid precautions outfits would be recommended. Miss Horsbrugh replied in the affirmative. She said Sir John Anderson was arranging for the supply to hospitals of inhaler apparatus for those suffering from lung conditions, whether caused by gas or otherwise.

Notes in Brief

Nearly one-third of the mothers evacuated from Glasgow have returned.

Sir Victor Warrender states that the Army recruits physical development depots were abolished on mobilization, and the buildings have been allotted to other uses.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to The EDITOR, British Medical Journal, B.M.A. House, Tavistock Square, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS.—All communications should be addressed to the Advertisement Manager (office hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House.

The Telephone Number of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The Telegraphic Addresses are
EDITOR OF THE *BRITISH MEDICAL JOURNAL, Aitiology, Westcent, London*
SECRETARY, *Medisecra Westcent, London.*

The address of the B.M.A. Scottish Office is 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh;* telephone 24361 Edinburgh), and of the Office of the Cumann Dochtúirí na h-Éireann (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin;* telephone 62550 Dublin.)

QUERIES AND ANSWERS

Dermatological Out-patients

Dr. P. Farrell (London, E.3) writes: Can anyone tell me where I can send my poorer patients for a second opinion on dermatological questions? I have made so many abortive telephone calls that I thought a general inquiry might better achieve the result I seek.

Purchase of Medical Books

Mr. H. J. McCurrich, M.S., F.R.C.S. (Hove, Sussex), writes: I should be glad to know why I can buy any medical book at a local bookseller's at list price and the local bookseller gets a profit on the transaction, yet I am inundated with circulars of medical publishers, who send me a list of medical books with the net prices and the cost of postage. It is usually cheaper to buy direct, but in the case of medical books the reverse is the case. I submit that not only should the publisher pay postage, but should allow discount to the medical profession, as drug manufacturers do, so that it comes to the same thing if the publisher sells to a bookseller or a doctor, but a doctor buying direct saves the middleman's commission. Meantime, when it is essential to exercise every economy, I would suggest to my colleagues that they buy medical books at list prices from their usual bookseller.

LETTERS, NOTES, ETC.

Second Attack of Scarlet Fever

Dr. Sydney Tibbles (London, W.1) writes: In 1914 I had a second attack of scarlet fever following one in infancy. A doctor friend sent for Dr. Porter, M.O.H. for Marylebone, who sent me to the London Fever Hospital for the first six weeks of the war. Probably the infection came from children seen at the Miller General Hospital when acting as oculist to the Greenwich Education Committee.

Mr. Bumble Misquoted

Dr. W. B. Bennett (Liverpool) writes: The writer of the medico-legal article in the *Journal* of September 9 (p. 590) probably thinks he is quoting Dickens when he describes the law as "a Hass," but Mr. Bumble said "a Ass." I suspect the numerous writers who are responsible for this misquotation have never read Dickens, but are merely quoting one another.

BRITISH MEDICAL JOURNAL

LONDON SATURDAY OCTOBER 14 1939

WEIL'S DISEASE IN THE NORTH-EAST OF SCOTLAND

AN ACCOUNT OF 104 CASES*

BY

L. S. P. DAVIDSON, B.A., M.D., F.R.C.P.Ed.
Professor of Medicine, the University of Edinburgh

AND

J. SMITH, M.D., F.R.C.P.
Bacteriologist, the City Hospital, Aberdeen

During the past few years increasing attention has been paid to the clinical, bacteriological, and epidemiological aspects of Weil's disease, with the result that it has been found to be much more prevalent and more widely distributed than was originally anticipated.

In 1934 (Davidson *et al.*) we published a clinical and bacteriological study of fifteen cases of this disease, twelve of which occurred in fish workers in Aberdeen. We suggested that workers among fish must be included in the occupational groups especially liable to Weil's disease. In 1936 (Davidson and Smith) we described the clinical manifestations and the biochemical changes in the blood and urine of forty-one cases, forty of which occurred in fish workers. Our bacteriological investigations established the connexion between the carriers of the disease (infected rats) and the sufferers from the disease (infected fish workers) through contaminated water and slime in the fish-cleaning and curing establishments. Later in the same year we showed that 24.3 per cent. of samples of blood removed from 210 fish workers who were in normal health gave a positive sero-reaction in dilutions ranging from 1 in 30 to 1 in 1,000, while in a control series of tests carried out on 406 samples of blood removed from individuals not engaged in the fish trade no positive reactions were obtained. From our experience we suggested that Weil's disease occurs in Aberdeen in three grades: (1) where the infection is so mild that symptoms are insignificant or absent; (2) where infection is moderate and the symptomatology is influenzal in type with no apparent jaundice; (3) where the infection is severe, with the characteristic picture described below. In the same paper we submitted to the fish trade our suggestions for the prevention of Weil's disease, which included a joint organized campaign for the extermination of the rodents, the rendering of premises rat-proof, the maintenance of a higher standard of cleanliness, and the use of a hypochlorite solution known as "chloros," which we found to have a lethal effect on leptospirae in a dilution of 1 in 4,000 without producing any deleterious effects that might interfere with marketing arrangements.

In the present communication we wish to describe the clinical manifestations of 104 cases of Weil's disease that have occurred in the North-East of Scotland between 1934 and 1939, and to discuss some of the bacteriological and serological investigations which we have carried out.

Analysis of Cases of Weil's Disease in Great Britain

In the analysis given below cases are included only if the clinical diagnosis was adequately confirmed by bacteriological or serological tests. Previous to 1922 proof of the occurrence of Weil's disease in Great Britain had never been obtained. In that year Manson-Bahr *et al.* (1922) isolated *L. icterohaemorrhagiae* from the blood of a seaman who, four days previously, had fallen into the Thames. In 1924 Gulland and Buchanan described an outbreak of epidemic jaundice among miners in East Lothian. Later Buchanan (1927) reported the clinical and bacteriological findings in twenty-two cases of Weil's disease. Alston and Brown (1937) reviewed the literature and stated that between July, 1933, and February, 1937, 142 cases with twenty-two deaths had been reported in various parts of Great Britain. The majority of cases had occurred in individuals employed as fish workers (forty-six), coal miners (thirty-four), and sewer workers (nineteen). More recently cases have been reported by Murgatroyd (1937) in a farm worker, by Stuart (1938, 1939) in tripe workers and sewer workers in Glasgow, by Robertson (1938) in individuals bathing in a stream in Hampshire, and finally by Rees (1939) and Sladden (1939) in miners in South Wales. The total number of cases in Great Britain in which the clinical diagnosis has received adequate bacteriological confirmation is therefore 185. To that number must now be added another sixty-three cases described in this communication for the first time. The grand total is accordingly 248, of which 109 have occurred in fish workers. Since the incidence of leptospiral infection in rats in Aberdeen (27.3 per cent.) is no higher than that found elsewhere in Great Britain, the large number of cases among fish workers and the frequency with which immune bodies can be demonstrated in the blood of healthy workers in the fish trade (24 per cent.) justify the conclusion that the risk of contracting infection is greater in that trade than in any other in this country.

---

* Read in opening a discussion at a joint meeting of the Sections of Services and Tropical Medicine and Public Health at the Annual Meeting of the British Medical Association, Aberdeen, 1939.

Occupational Incidence and Geographical Distribution of Cases in Aberdeen

Of 104 cases reported in this paper ninety-eight occurred in fish workers (filleters, curers, porters, and carters). The remaining six were in farm workers (two), labourers constructing sewers (two), and an engineer in a rag factory, and one arose from harbour immersion. One case occurred in Aberdeenshire and three in Kincardineshire, the remainder arising in the city of Aberdeen. A study of the streets in which the one hundred patients were employed showed that ninety-seven worked in a small area adjacent to the harbour and the fish market.

An investigation into the distribution of the ninety-seven cases in relation to the numerous fish-curing yards in Aberdeen showed that infection had been contracted in no fewer than fifty-three different establishments. In each of thirty-six yards only one case had occurred, whereas in four yards six to eight individuals developed the disease. Further investigation revealed the fact that the number of workers in the yards with six to eight cases was, on the average, six to eight times greater than the number employed in the establishments in which one case had developed. It may be presumed, therefore, that the variation in the incidence of the disease in the different yards is at least largely explicable on the basis of the number of workers exposed to infection. It is worth noting that one firm with a large number of employees has never had a case of Weil's disease during the past five years. Accordingly we investigated the working conditions, and found that the type of work undertaken was almost entirely connected with the salt fish trade, in contrast to all the other establishments where Weil's disease has occurred, which specialize in the fresh fish trade.

Yearly and Monthly Distribution of Cases

The number of cases of Weil's disease which have occurred annually in Aberdeen during the past five years has been fairly constant. In 1934 there were twenty-four cases, in 1935 and 1936 seventeen cases, in 1937 twenty cases, and in 1938 twenty-six cases. It is clear that the advice we offered to the trade in 1934 in regard to preventive measures has never been utilized.

An analysis of the monthly distribution of cases in each of the five years suggests that Weil's disease occurs least often in February and March (a total of four cases in five years) and most often in August and September (thirty-one cases in five years). If the year is divided into two halves it is found that seventy-one cases occurred between July and January and thirty-three between February and June. Since the fish trade operates at approximately the same degree of activity all the year round it must be assumed that variations in the seasonal distribution of cases depend either on an increased or decreased viability of the leptospirae to seasonal variations of environmental temperature or on changes in the habits of the rats at different seasons of the year.

Age and Sex Incidence

Table I gives the age and sex incidence of 104 cases of Weil's disease occurring in the North-East of Scotland. There were fifty cases in males and fifty-four in females. The total number of males employed in the industry is 786 and the number of females 1,277. It will be noted that nearly half the cases occurred before the age of 20 and that four-fifths of these patients were females. This finding is related to the working conditions of the fish trade, in which young girls between the ages of 15 and 20 carry out the procedures of cleaning, gutting, and filleting fish. Between 80 and 90 per cent. of the workers below the age of 20 are females, whereas after the age of 30 the majority of the employees are males engaged as foremen, porters, carters, etc.

Table I.—*Age and Sex Incidence of Cases*

Age Group	Sex	Cases	Deaths
14–20	M	9	0

	F	0	0
51+	M	8	4
	F	1	0
Total		104	6

Mortality Rates

Table II gives the death rate from Weil's disease in the 104 cases in the North-East of Scotland. The figure of 5.7 per cent. is a little over one-half of that obtaining in Holland. We ascribe the low death rate to the high incidence of healthy young girls in the trade. It will be noted that there were no deaths among the fifty-four females. The effect of advancing years in increasing the dangers of the disease is well brought out by the four deaths among the nine patients over 50 years of age. The same tendency is noted in regard to morbidity. In general, middle-aged and elderly patients were more seriously ill than young ones. The liver in such patients seems to be peculiarly susceptible to the toxaemia of Weil's disease, and if in addition there is a history of an alcoholic tendency the prognosis becomes correspondingly more serious. At least two of our fatal cases gave a history suggestive of having partaken of excessive spirits over a long period.

Table II.—*Analysis of Deaths*

	Cases	Deaths	Mortality per Cent.
Total	104	6	5.7
Male	50	6	12.0
Female	54	0	0.0
Under 50 years.. ..	95	2	2.1
Over 50 years	9	4	44.4

Clinical Manifestations

GENERAL

These will only be described briefly, as a full description of the symptoms and signs will be found in our previous publications.

The course of the disease may be divided into three stages. The first or febrile stage lasts approximately one week, and during this time septicaemia occurs, antibodies are not detectable in the blood, and spirochaetes are not found in the urine. The patient is suddenly taken ill and complains chiefly of headache, vomiting, and severe muscular pains all over the body. In severe cases there is marked prostration, and the temperature rapidly rises to 102–104° F. Table III gives the percentage incidence of the various symptoms and signs in the 104 cases. Since jaundice rarely appears before the fifth day of the illness a diagnosis of influenza is usually made. The

TABLE III.—*Percentage Incidence of Clinical Manifestations in 104 Cases*

Symptoms	Present in	Percentage
Sudden onset	104	100
Initial chill	71	68
Fever	103	99
Headache	91	87
Muscular pains	103	99
Prostration	46	44

Haemorrhages: mild	61	58
„ severe	19	18
Enlarged liver	28	26
Palpable spleen	1	0.9
Adenopathy	13	12
Meningitis	10	9

presence of a marked conjunctivitis (pink-eye) and the evidence of a toxic nephritis (albumin, cells, and casts) may be helpful in suggesting the correct diagnosis, particularly if the patient is employed in an occupation in which the hazard of leptospiral jaundice is high.

The second or toxic stage is characterized by the absence of spirochaetes and the development of antibodies in the blood and the excretion of organisms in the urine. If jaundice has not appeared by the beginning of the second week the case may be considered to be mild; the symptoms then rapidly abate. In moderately severe cases which are going to do well the fever abates and the clinical condition improves; but the jaundice continues for another week or two, and the signs of a toxic nephritis are present for at least a month. In cases doing badly the jaundice becomes intense, the urinary output falls, the blood urea rises rapidly, purpura into the skin and from the mucous membranes occurs, and a falling blood pressure and steadily mounting pulse indicate the gravity of the situation.

The third or convalescent stage is characterized by the development of antibodies in the blood and by the excretion of organisms in the urine. The distressing symptoms gradually subside, but convalescence is greatly prolonged in those who have been seriously ill. An interesting second rise in temperature occurs during the third week of the illness in approximately half the cases.

SPECIAL

(*a*) *Blood Examination.*—Red and white cell counts and haemoglobin estimations were carried out in a series of cases. The leucocyte count varied, according to the severity of the disease and the individual's response to the infection, from 10,000 to 30,000 leucocytes per c.mm. of blood. The increase was essentially due to an excess of neutrophil polymorphonuclear leucocytes, and a typical shift to the left was noted. The red cell count and haemoglobin were consistently reduced in all cases in which toxaemia was severe, and particularly if purpura was a prominent symptom. In such cases an erythrocyte count of 2,500,000 to 3,500,000 with a haemoglobin concentration of 40 to 60 per cent. was not uncommon. In one case with severe purpura the erythrocytes fell to 1,400,000 and the haemoglobin to 26 per cent., and a transfusion of blood had to be given.

(*b*) *Biochemical Estimations.*—The icteric index was estimated in eighty-three cases. In 80 per cent. a figure of 10 units or higher was found. Figures for the blood urea are available in eighty-two cases. In 60 per cent. a figure of 40 mg. per 100 c.cm. or over was found. Of the six fatal cases one patient died with anuria shortly after admission to hospital, and no figures are available for either the blood urea or the icteric index. Four died with the blood urea greatly increased—namely, 161, 250, 300, and 397 mg. per 100 c.cm. In the sixth case the blood urea was only 89 mg. per 100 c.cm., but this estimation was made on a sample of blood removed on the fourth day of the illness. The patient died at home on the eighth day after the onset, without being admitted to hospital. It is obvious, therefore, that a high blood urea is a sign of serious prognostic importance. Nevertheless it must be remembered that recovery can occur despite a greatly increased blood urea. Thus we have had seven patients recover whose blood urea was respectively 128, 128, 143, 152, 161, 202, and 300 mg. per 100 c.cm. With regard to the icteric index in the fatal cases, the figures were 60, 63, 67, 89, and 150. In contrast, in patients who have recovered we have obtained figures of 100, 166, and 187. In the six fatal cases death occurred between the eighth and tenth days of the illness, by which time the maximum degree of jaundice may not have developed.

(*c*) *Meningitis.*—In ten cases the symptoms and signs were strongly suggestive of meningitis. The clinical diagnosis was confirmed in each case by examination of the cerebrospinal fluid. The protein content was raised in most instances, but the figure varied between 25 and 80 mg. per 100 c.cm., the average being 54 mg. The number of cells per cubic millimetre of cerebrospinal fluid was also increased. It varied between 30 and 243, the average being 125. The increase in cells was proportionately greater than the increase in protein. Differential counts showed that in the early stages the increase in cells was due to an excess of neutrophil polymorphonuclear leucocytes. Later this was replaced by a lymphocytosis. The cerebrospinal fluid was tested for the presence of immune bodies, and in six cases a positive result was obtained. The titre at which the cerebrospinal fluid agglutinated the leptospirae was low in five cases—1 in 2 (three cases), 1 in 6 (one case), 1 in 30 (one case)—while in the sixth a figure of 1 in 300 was obtained. The cerebrospinal fluid was injected into guinea-pigs, but in no instance were leptospirae recovered. Although the ten patients with Weil's disease complicated by meningitis were severely ill, complete recovery occurred in each case.

Treatment

(*a*) *Symptomatic.*—Treatment on the general lines suitable for any severe febrile disease is required. This includes rest, good nursing, tepid sponging, and the use of diaphoretic, analgesic, and hypnotic drugs. A simple alkaline mixture containing potassium citrate, sodium bicarbonate, and liq. ammon. acetatis is worthy of trial for combating the gastritis and facilitating the urinary excretion. The diet should be low in fats and protein and rich in carbohydrate, since hepatic and renal damage is present. Plenty of fluids and fruit juice, sweetened with glucose, should be given frequently. Iron in full doses will be required to correct the hypochromic anaemia which so often develops.

(*b*) *Specific.*—Ample evidence has been accumulated in Holland and elsewhere in regard to the value of anti-leptospiral serum. A reduction both in the mortality of the disease and in the severity of the toxaemia has been shown to result, particularly if the serum is given early—that is, within the first four days. After the seventh day, when the septicaemic stage is over, the beneficial effects are much less marked. The amount of serum advocated is 10 to 20 c.cm., given intramuscularly or intravenously, the dose to be repeated in four to six hours as required.

Bacteriological Findings in Weil's Disease

The final diagnosis of Weil's disease is largely dependent on the recovery of leptospirae from the patient or on the demonstration of immune bodies in the serum when convalescence is being established. In this investigation culture of the blood for leptospirae has not been extensively employed. When specimens of clotted blood were sent for examination the serum was removed for serologic and biochemical examination, and the clot was then injected intraperitoneally into two young guinea-pigs. Table IV shows the results obtained when the first specimen of blood received from each of eighty patients was injected into guinea-pigs. Thus, up to the fourth day after the onset of illness the leptospira could be recovered from all cases. After that day the chance of recovering the organism rapidly decreased until on the seventh and eighth days it was found in the blood of exceptional cases only. These results are in accord with those reported by Japanese workers.

Table IV.—*Blood: Bacteriological Findings in 80 Cases (Presence of leptospirae as shown by guinea-pig inoculation)*

	Day of Disease										
	1	2	3	4	5	6	7	8	9	10	11+
No. +	0	2	3	11	3	8	1	1	0	0	0
No. —	0	0	0	0	6	15	14	10	1	1	4
% +	—	100	100	100	33	35	7	10	0	0	0

As regards the serological test, the findings are given in Table V. In no case was a positive serum reaction obtained before the third day after the onset. Thereafter the immune bodies rapidly increased in the serum until on the fifth day 50 per cent., and by the ninth day 100 per cent., of cases had given a positive reaction. Furthermore, the actual titre of the serum also increased from 1 in 10 in the early stages to 1 in 10,000 or 1 in 30,000 or more by the tenth day. In only three cases were leptospirae isolated from the blood at a time when immune bodies could be demonstrated simultaneously in the serum. In Case 37 the blood taken on the sixth day showed the presence of leptospirae and a positive serum reaction of 1 in 30; in Case 72 the specimen was collected on the fourth day and gave a positive result on guinea-pig inoculation and an agglutination reaction of 1 in 30; and finally in Case 81 the blood showed leptospirae on the seventh day and a weak serum reaction of 1 in 10.

Table V.—*Serological Tests on Serum*

	Day of Disease										
	1	2	3	4	5	6	7	8	9	10	11+
No. negative 1/10 dilution	—	2	3	9	5	9	3	2	0	1	0
No. positive 1/10 dilution or greater	—	—	—	1	5	16	19	23	8	11	62
% positive 1/10 dilution or greater	0	0	0	10	50	64	86	92	100	91	100
Positive reactions : Dilution of serum											
1/10	—	—	—	—	—	3	3	—	—	—	—
1/30	—	—	—	1	4	3	3	1	—	—	—
1/100	—	—	—	—	1	5	4	2	1	—	3
1/300	—	—	—	—	—	4	5	5	3	1	8
1/1,000	—	—	—	—	—	—	3	13	2	5	8
1/3,000	—	—	—	—	—	1	—	2	2	1	5
1/10,000 ..	—	—	—	—	—	—	—	—	—	3	12
1/30,000 ..	—	—	—	—	—	—	1	—	—	1	26

Again, in four cases—Nos. 15, 41, 54, and 87—the first examination of the blood carried out between the fifth and the eighth day of illness showed a negative guinea-pig inoculation test and a negative serum reaction. It is therefore necessary to keep in mind the possibility that bacteriological and serological investigations undertaken in suspected cases of Weil's disease within eight days of the onset may give negative results, and accordingly further specimens of blood may be required before the diagnosis can be finally settled.

The leptospira can also be recovered from the urine, but it is essential that the specimen must be inoculated into guinea-pigs as soon as possible after being passed. Two hundred and eleven specimens of urine from eighty-eight cases of proved Weil's disease were tested by this method. In no instance has it been possible to recover the leptospira from specimens collected within the first seven days of the disease. In the period eight to fourteen days after the onset 19.3 per cent. of samples were positive, in the period fifteen to twenty-one days 21.5 per cent., and in the period twenty-two to twenty-eight days 9.5 per cent. Thereafter the results were negative. It would appear, therefore, that at no time during the course of the illness can virulent leptospirae be recovered with certainty from the urine.

Agglutinins may also be demonstrated for *L. icterohaemorrhagiae* in the urine of patients convalescing from the disease. This is probably due to the fact that albuminuria is a constant feature of the disease, and the immune bodies are excreted in a dilute form attached to the euglobin. A series of 100 observations have been made in fifty-two proved cases of Weil's disease, and the results are recorded in Table VI. In the first week of the illness three out of eighteen (16.6 per cent.), in the second week twenty out of twenty-eight (71.4 per cent.), in the third week thirty-four out of thirty-seven (91.8 per cent.), and after the third week seventeen out of seventeen (100 per cent.) gave positive reactions in dilutions of 1 in 2 or greater. The highest urinary titre recorded during convalescence was 1 in 300.

Table VI.—*Serological Examination of Urine Specimens*

Summary

The clinical manifestations of 104 cases of Weil's disease occurring between 1934 and 1939 are described.

In the paper are discussed some of the bacteriological and serological investigations carried out.

THE ANTIRACHITIC VALUE OF HUMAN MILK

BY

J. C. DRUMMOND, D.Sc.

C. H. GRAY, B.Sc., M.B., B.S.

AND

N. E. G. RICHARDSON, B.Sc., M.B., B.S.*

(From the Biochemical Department, University College, London)

It is a surprising fact that the extensive literature on vitamin D does not contain precise information giving the range of antirachitic potency of human milk. It is a matter of particular importance when the character of the diet consumed by a large proportion of the people in this country is borne in mind. Our knowledge regarding the assimilation of bone-forming elements in the diet of mammalian species has been largely built up on the results of experiments on animals; these have taught us how great an importance is to be attached not only to vitamin D but to the total daily intakes of calcium and of phosphorus in one form or another, as well as the ratio (Ca/P) between these intakes. An admirable summary of the existing information regarding the significance of the level of intake of these mineral elements has recently been provided by Shohl (1938), but, broadly speaking, it can be said that, at any rate one level of Ca *or* P intake—assimilation—in the absence of supplementary factors such as members of the vitamin D group, is most satisfactory within a certain and rather narrow range of values for the Ca/P ratio. Moreover, at any one Ca/P ratio the assimilation tends to improve as the total intake of the two components rises. Finally, it should be noted that the administration of vitamin D at any level of intake or Ca/P ratio improves the deposition of bone mineral, but, in general, its influence is most pronounced when the former is low and when values of the ratio are outside the desirable range.

In days when fish-liver oils, antirachitic concentrates, and even the pure vitamins of the D group are so readily available, it is easy to forget that until the introduction in England in the late eighteenth century of cod-liver oil for the treatment of bone affections the ordinary person had no such means of protection against rickets. Accustomed as we are to-day to think in terms of doses of hundreds and thousands of international units of vitamin D, the amounts supplied by ordinary foods must strike us as curiously insignificant (milk 0.5 to 4, butter 20 to 100, egg yolk 150 to 500, liver 10 to 50 I.U. per 100 grammes) (Fixsen and Roscoe, 1937–8). What, then, was the position in England before the virtues of cod-liver oil were recognized? In a recent publication Drummond and Wilbraham (1939) examined this question in some detail, with the result, it is thought, that evidence has been obtained to show that the striking outburst of rickets which appears to have occurred in Southern England and Ireland towards the end of Tudor times, and which attracted great interest, was due primarily to a sharp fall in the consumption of dairy produce. It is there suggested that the outbreak of the disease was more related to a decreased intake of calcium in many diets than to a reduction in the amount of natural vitamin D, although doubtless both played a part.

Calcium Requirements

The remarkable facts revealed by the discovery of vitamin D and the investigation of its role have tended to direct attention rather unduly, so far as the study of human rickets is concerned, from the significance of the intake of bone-forming elements. The surveys of Sir John Orr (1936) and of others have given convincing proof how large a proportion of our population to-day are living on diets which fail to supply the estimated physiological requirement for calcium. These diets are in striking contrast to those of the relatively poor Englishman of centuries ago, when, thanks to wholemeal breads and large consumption of milk and cheese, the daily intake of calcium was often as much as four to six times that of the poor to-day. Seventeenth century diets of simple folk—for example, sailors or the patients of St. Bartholomew's Hospital—provided no less than 2 grammes of calcium a day, and, let it be noted, the Ca/P ratios were often excellent. It is not unreasonable to think that the human requirement for vitamin D would probably be at its minimum under such conditions. They are rarely found to-day. Hundreds of thousands of the poorer sections of the community are living at the present time on diets supplying from 0.2 to 0.5 gramme of calcium daily—intakes which are all too often associated with relatively high intakes of phosphorus, giving ratios of below 0.5 and not infrequently as low as 0.2.

Experiments have already clearly demonstrated the beneficial effect of supplementing diets of this character with additional calcium, thereby not only raising the total intake of bone-forming salts but also bringing the figure for the Ca/P ratio nearer the optimum range of 1 to 2. The improvement particularly affected the bony structures, and in this connexion it is important to remember that no additional vitamin D was supplied (Coward *et al.*, 1938; Gaunt *et al.*, 1938).

Factors leading to Rickets

The surprisingly small amount of vitamin D in cows' milk (17 to 26 I.U. per quart in summer and a mere 5 to 8 I.U. per quart in winter) and the discovery of the fact that the higher values in summer are due not to a change of diet but to the direct effect of exposure to sunshine and skyshine (Campion *et al.*, 1937) raised the very important question whether the smaller incidence of rickets among breast-fed infants, as compared with those reared on cows' milk, is to be ascribed to a more efficient utilization of the bone-forming salts, to a richer content of antirachitic vitamin in mothers' milk, or perhaps to both factors.

---

* During the tenure of the William Gibson Research Scholarship of the Royal Society of Medicine.

The literature on the antirachitic value of human milk is unsatisfactory. Hess and Weinstock (1927) found that 25 to 30 ml. of human milk was required to prevent rickets developing in rats fed on a rachitogenic diet, whereas 20 to 25 ml. of cows' milk was effective. The results of this investigation, and of similar experiments subsequently reported by other workers, are misleading because striking improvements in the condition of the bones of animals fed on certain types of rachitogenic diets can be brought about merely by improving the Ca/P ratio. The apparent superiority of cows' milk as an antirachitic agent revealed by such experiments could be ascribed more correctly to its higher content of these elements than to any greater concentration of vitamin D.

In order to assay the vitamin D content of milks it is advisable to separate the fat and administer it to the animals fed on a rachitogenic diet. Few investigators have troubled to do this, and none, so far as we are aware, has attempted to make assays of the vitamin D content of human milk-fat by the modern method of evaluation against the approved international standard of vitamin D. The specimens examined by us were not entirely satisfactory in that they were for the most part random samples collected during the first two months of pregnancy from patients attending the infant welfare department of University College Hospital. Unfortunately, it was not practicable to obtain samples fully representative of the twenty-four-hours yield. On receipt of the specimens in the laboratory sufficient was retained for the calcium and phosphorus analyses (see later), the remainder being treated with alcohol and a mixture of ether and light petrol in order to separate the fat. The isolated fat was administered in carefully measured doses to groups of rats in which rickets had been produced by a rachitogenic diet. The degree of rickets at the beginning of the experiment and after ten days' dosage with the milk fats was assessed by *x*-ray examinations of the leg bones.

The milks were also analysed for total and dialysable calcium and phosphorus, the method for the phosphorus analyses being that of Kuttner and Lichtenstein (1930). For determining the dialysable Ca and P we used a suitable modification of the "static" dialysis method employed by Lampitt and his co-workers (1933, 1934, 1937). Usually about 120 ml. of milk, from which as much fat had been removed as possible by centrifugation, was dialysed against 3.3 ml. of water.

This provided about 2 ml. of dialysate suitable for analytical purposes. The results as a whole are set out in Table I. An attempt was made to ascertain whether any correlation could be traced between the results of the analyses of the individual milks and such information as was available regarding the nutritive state of the mother. Unfortunately it was not found possible to obtain precise details regarding the everyday diet of the women, but, by questioning, a certain amount of information was gathered which permitted a rough classification to be made, partly on the basis of the general character of the diet and partly on statements regarding the total income, number in the family, rent, etc.

Factors influencing the Vitamin D Content of Milk

An attempt has been made to correlate the results with various factors which are believed to influence the vitamin D content of cows' milk. In the first place, there is no evidence of a seasonal variation. The mean value of sixteen samples taken during the winter months (October to March, inclusive) is 5.9 I.U. per 100 ml., which compares well with that of 6.2 for the ten summer samples. This is a reasonable conclusion, for one would scarcely expect an effect from the influence of sunshine or skyshine to be noticeable in working-class women in London. The mean value of the whole twenty-six samples is 6 I.U. per 100 ml.

What seem to be significant differences appear when the results are classified according to estimates of the intakes of vitamin D by the women (Table II). The value of these results is open to question because, in the first place, the numbers in the groups are small, and, secondly, because we had not the information to provide an accurate estimate of the intake of vitamin D in the mothers' diet. With this reservation, however, we are inclined to believe that the results show that the vitamin D content of human milk is increased by raising the vitamin D content of the diet. Bunker, Harris, and Eustis (1933) have presented evidence that the administration to women of cows' milk artificially treated to increase its vitamin D value will raise the antirachitic value of their milk.

We are inclined to think—although again caution is necessary in view of the small number of samples analysed—that approximation between the mean antirachitic potency of the milk yielded by women on diets supplying in all probability between 100 to 250 I.U. of vitamin D daily and that of the milk from women dosed during the latter half of pregnancy with much larger amounts of vitamin D (approximately 1,000 I.U. daily) in the form of halibut-liver oil supplement indicates that 10 I.U. per 100 ml. of breast milk represents about the normal maximum value. Possibly the same evidence can be put forward to indicate that an intake of about 200 I.U. represents the *minimum* daily requirement of the nursing mother. Our results appear to show that the large doses of vitamin D given to some of the mothers over several months of pregnancy failed to bring about anything approaching a proportional increase in the vitamin D content of the milk. It may be, therefore, that there is an optimum concentration of this substance regulated by the mammary gland. It will be recalled that Gerstenberger, Hartman, and Smith (1927) failed to increase the antirachitic potency of breast milk by giving a teaspoonful of cod-liver oil (250 I.U.?) daily to a woman already receiving an adequate diet.

Our estimate of 200 I.U. of vitamin D as the *minimum* intake of the pregnant and lactating woman is in reasonable agreement with the daily intake of 300 I.U. recently recommended by the Committee of the Health Organization of the League of Nations.

TABLE II.—*Attempt to correlate Vitamin D Content of Diet and of Milk*

Estimated Vitamin D in Diet. I.U. Daily	Vitamin D Content of Milk Fat. I.U. per gramme	Vitamin D Content of Milk. I.U. per 100 ml.
Group A. Daily D intakes probably less than 100 I.U.		
35	1	4
50	1	4
50	1	4
70	1	4
70	0.5	4
85	0.5	2
Mean	0.8	3.7
Group B. Daily intake probably above 100 I.U.		
125	3	18
130	2.7	8

Vitamin D Requirement for Bone Formation in Infants

It is necessary now to consider our results from the standpoint of bone formation in infants. There is, or, at all events, there has been until recently, no very clear idea how much vitamin D is required by an infant. For some time past it has been rather generally accepted that artificial feeding with cows' milk should be supplemented with vitamin D therapy. All sorts of doses have been recommended, but a considerable proportion of paediatricians have been in favour of daily doses of the order of 1,000 I.U. It now appears that in the majority of cases this is too much.

In a series of careful studies, in which cows' milk which had been artificially "fortified" in respect to vitamin D was used, Jeans and Stearns (1937, 1938a) were able to show that about 70 to 100 I.U. a day during the first three months will prevent the appearance of rachitic symptoms in the majority of full-term infants. This level of intake, provided by approximately 120 ml. per kg. of body weight of milk containing 12 I.U. per 100 ml., was not found adequate for premature babies, nor did it ensure optimum growth. Full protection was given when the intake of vitamin D was three to four times as great. The very large doses—for example, 1,000 to 5,000 I.U daily—which were so popular in the early days of enthusiasm for vitamin D therapy and which are still not infrequently employed, are probably unnecessary and actually appear sometimes to exert a definitely inhibitive action on growth (Jeans and Stearns, 1938b).

Influence of Calcium-Phosphorus Ratio

It is interesting that a satisfactory intake of cows' milk providing 12 I.U. of vitamin D per 100 ml. has been found to produce good calcification in normal full-term infants, because the amount of vitamin D taken by the young child would be of the same order as that provided by the milk of a well-nourished mother. This probability has to be considered together with the fact that the assimilation of the bone-forming elements is better (40 to 60 per cent.) when the child is fed on mother's milk than when cows' milk is used (20 to 30 per cent.). The reason for this better utilization has not yet been determined, but it may be important that the Ca/P ratio of human milk approximates to that of bone mineral, whereas the Ca/P ratio of cows' milk is considerably smaller.

	Ca (mg.%)	P (mg.%)	Ca/P Ratio.
Human milk	27–34 ..	13–17 ..	2.0
Cows' milk	100–160 ..	70–100 ..	1.5
Bone mineral (dahlite) $2Ca_3(PO_4)_2.CaCO_3$		.. ..	2.2

The relatively small concentration of calcium and phosphorus in human milk as compared with cows' milk raises several curious problems, of which the most important has been revealed by the careful studies of Leitch (1937). She has shown that the *total* intake of calcium when mother's milk is taken, much less the quantity actually *retained*, is often insufficient to provide the amount calculated as being requisite to maintain the composition of the body either at the maximum figure of 10 grammes of calcium per kilogram of body weight or at the smaller estimate of 8.13 grammes of calcium per kilogram (Hamilton, 1922).

Consideration of this extraordinary finding has led Dr. Leitch to consider the possibility that breast-fed infants must often exhibit not only imperfect calcification of new matrix but also osteoporotic changes in bones which at birth were relatively firm. It may be a fact that undetected rachitic changes are much more common in breast-fed infants than is suspected (Maddox, 1932), and it may also be true that if it were possible to make histological examinations we would be surprised at the frequency with which osteoporotic changes occur in the first half of lactation (Zarfl *et al.*, 1923). There seem to be only two explanations of the figures Dr. Leitch has produced. Either the newly born infant carries a reserve store of calcium sufficient to provide for adequate calcification during the months when the mother's milk does not provide enough —and it must be borne in mind that there is such a protective storage of iron—or the data of the metabolism experiments which Dr. Leitch has used for her analysis are misleading, perhaps because the milk was not of such a quality as to favour optimum calcium retention.

It remains uncertain in view of the evidence reviewed by Leitch whether changes in the dietary intake of calcium or phosphorus are reflected to any significant extent in the composition of a mother's milk. Our own results, admittedly scanty, suggest that such an effect is not detectable, at all events in the first two or three months of lactation. Some of the mothers we investigated had been receiving about 2 grammes of calcium lactate daily during the latter half of pregnancy, but this supplement to calcium-deficient diets did not appreciably influence the calcium content of their milks.

Conclusion

There is certainly need for more information, not only about the composition but also about the *yield* of milk from mothers whose diet, adequate in all other respects, provides at least 2 grammes of calcium, 1.5 grammes of phosphorus, and 300 I.U. of vitamin D daily. If such milk were made the subject of metabolic investigation on infants it is possible that some of the disturbing discrepancies would be dispelled.

Summary

The literature on vitamin D does not contain precise information as to the range of antirachitic potency of human milk.

The results of an analysis of human milks for vitamin D, calcium, and phosphorus are here recorded and an attempt made to correlate the vitamin D content of diet with that of the milk.

The conclusions derived from the analysis are given.

The expenses of the investigation have in part been defrayed from a grant by the Medical Research Council to one of us (J. C. D.), of which grateful acknowledgment is made.

THE PATHOLOGY OF CHLORIDE METABOLISM IN MAN*

BY

ALEXANDER LYALL, M.A., M.D., M.R.C.P.
Lecturer in Clinical Chemistry, University of Aberdeen

During the past ten years considerable significance has been attached to disturbances of the metabolism of chlorides in man. The information gained from observations on patients and experimental work in animals has applications in diseases so diverse as intestinal obstruction, pyloric stenosis, chronic nephritis, oedema, obesity, hypertension, and Addison's disease. The principles which control the chloride balance of the body and determine the nature of the processes of absorption, secretion, reabsorption, and excretion of chloride are of importance in these diseases, and their significance is already reasonably well established. The phenomena which control the exchange of chlorides in tissue cells and fluids are not yet fully explained.

Normal Cycle of Chloride Metabolism

The average normal adult on an ordinary diet ingests about 12 grammes of chloride daily. This can be easily verified by estimating the daily excretion of chloride in the urine. In addition to the urinary excretion, small quantities of chloride are excreted in the faeces and limited amounts in the skin secretions (probably not more than 2 grammes daily in the absence of active perspiration). In forced sweating the skin loss in chloride may amount to 10 or 12 grammes daily (McCance, 1938). It should be borne in mind that clinical analogies to such abnormal skin losses occur in conditions where there is intense sweating, in acute febrile disturbances, in the sweating of tuberculosis and acute rheumatism, in pneumonia, in thyrotoxic crises, and in heavy muscular exertion in hot surroundings.

Apart from external losses by these routes—skin, urine, and faeces—there occurs a continual circulation of chloride to and from the intestinal lumen. The total quantities of chloride in circulation in this way daily in the normal person are somewhat indefinite. Approximate measurements of volume and chloride content of the various alimentary secretions give some basis for calculation, as shown in Table I (McCance, 1936).

TABLE I.—*Intestinal Secretions : Chloride Content*

Secretion	Vol. (c.cm.) in 24 Hours	Authority	Chloride Content (grammes)
Saliva	1,500	Bidder and Schmidt	7.5
Gastric juice ..	2,000–3,000	Nicol and Lyall	17
Bile	300–500	Pfaff and Balch	4
Pancreatic juice	500–800	Wohlegemuth	8
Succus entericus	3,000	Pregl	18
Total chloride			54.5

These figures are quite approximate, and probably form a conservative estimate.

Nicol and Lyall (1939a and 1939b), for example, as shown in Table II, were able to remove 29 grammes NaCl by gastric aspiration from a male patient in the first day, and a total of 93 grammes in six days' aspiration, the amount on the first day representing the uninfluenced gastric secretion of chloride in this individual.

---

* Read in opening a discussion in the Section of Physiology and Biochemistry at the Annual Meeting of the British Medical Association, Aberdeen, 1939.

TABLE II.—*Gastric Secretion: Chloride Content*

Date	Gastric Aspiration (c.cm.)	Chloride Content %	Total Chloride (Grammes)
12/9/38	4,260	0.680	29
13/9/38	2,320	0.707	17
14/9/38	2,080	0.628	13
15/9/38	1,690	0.533	9
16/9/38	1,800	0.595	11
17/9/38	2,070	0.641	14

Total chloride secreted: 93 grammes; average, 15 grammes.

In a patient suffering from biliary fistula whom I have been able to investigate recently, the biliary flow showed an average volume of 1,000 c.cm., with chloride content of approximately 7 grammes daily, as shown in Table III.

TABLE III.—*Biliary Secretion: Chloride Content*

Date	Bile Vol. (c.cm.)	Chloride Content %	Total Chloride (Grammes)
24/4/39	780	0.70	5.5
25/4/39	540	0.73	4.0
26/4/39	480	0.69	3.3
27/4/39	720	0.73	5.3
28/4/39	1,200	0.73	8.9
29/4/39	930	0.70	6.5
1/5/39	1,080	0.72	7.8
2/5/39	1,380	0.66	9.2
3/5/39	1,020	0.70	8.5
4/5/39	1,320	0.70	9.3
6/5/39	1,320	0.69	9.2
8/5/39	1,200	0.70	8.5
Average	1,000	0.70	7.2

It would thus seem that about 50 to 60 grammes of sodium chloride is secreted into the alimentary canal in twenty-four hours, and the amount may be considerably greater in certain individuals. The actual rate of secretion is undoubtedly greater than 3 grammes hourly, and must take place relatively quickly during digestion and absorption of meals. This exchange would seem to make considerable demands on the available stores of chloride in the circulating blood and body fluids, an amount which different estimates place between 90 and 160 grammes for a man of 60 kilogrammes of body weight (Bartlett, Bingham, and Pederson, 1938).

We must assume that reabsorption occurs almost as rapidly as excretion, since no major reduction in the plasma chloride level was found by Dodds and Smith (1923) during gastric digestion. These workers found a fall of 10 to 15 mg. per 100 c.cm. in the plasma chloride during the first hour. In the second hour, while gastric secretion remained vigorous, the plasma chloride remained constant, and later showed a slight increase, to return to normal fasting level. The chloride secreted in the gastric contents is very rapidly reabsorbed by the intestine, and again forms part of the chloride store in the tissue fluids and blood plasma. The question of intestinal absorption of chloride is obviously rather a complicated physiological puzzle, since intestinal secretions contain up to 0.64 per cent. NaCl, while the chloride concentration of the intestinal contents for absorption is of the same order. The help of the physiologist is obviously required in the explanation of this anomaly.

Regulation of Chloride Content of Body Fluids

The regulation of the chloride content of the body fluids is dependent on the chloride content of the blood plasma. Most workers agree that this value remains between the limits of 580 and 620 mg. per 100 c.cm., values above 600 mg. per 100 c.cm. being found only occasionally. The chloride content of whole blood is considerably lower at about 440 mg. per 100 c.cm. on account of the low chloride value of the red blood cells. The exchange of chloride between blood plasma and body fluids forms one of the major means for stabilization of osmotic tension between those fluids. Table IV shows the average chloride content of the various body fluids.

TABLE IV.—*Chloride Content of Body Fluids*

Fluid	Chloride (as NaCl) mg. per 100 c.cm.
Blood plasma	600
Whole blood	438
Saliva	460
Gastric juice	670
Bile	700
Pancreatic juice	230
Jejunal juice	750
Ileal juice	400
Cerebrospinal fluid	730
Lymph	630
Milk	160
Sweat	350

The main controlling influences concerned in the maintenance of the chloride content of the blood plasma and body fluids are (*a*) the kidney itself and (*b*) adequate intake of chloride. Of these the former plays the major part, cessation of chloride excretion occurring as soon as the plasma chloride shows any tendency to diminution. So effective is this check against chloride loss that a minimal intake of chloride can be experienced for several days without any reduction of the plasma chloride level. The level of the plasma chloride at which renal excretion of chloride ceases is about 520 mg. per 100 c.cm. (Anderson and Lyall, 1937), as shown in two ways by Tables V and VI.

TABLE V.—*Case of Intestinal Obstruction: After Relief*

Time	Plasma Chloride mg. per 100 c.cm.	Urine Chloride mg. per 100 c.cm.
1 day	467	Nil
2 days	455	20
4 "	467	20
5 "	496	29
6 "	528	154
7 "	555	233
8 "	580	440

TABLE VI.—*Case of Gastric Aspiration*

Time	Plasma Chloride mg. per 100 c.cm.	Urine Chloride mg. per 100 c.cm.
1 day	606	310
2 days	599	204
3 "	526	20
4 "	467	21
5 "	410	10

This level of the renal threshold for NaCl is practically constant in health, although it may be altered in either direction in renal disease, with the kidney failing to pass chloride at levels above the usual renal threshold as in certain cases of renal disease with oedema, or allowing chloride to pass into the urine at values below 520 mg. per 100 c.cm. in some cases of intestinal obstruction and alkalosis with secondary toxic nephritis.

Requirements of Sodium Chloride

Although the average daily intake of sodium chloride is between 6 and 12 grammes, a large proportion of this amount is excreted daily. It seemed of importance, with regard to replacing the loss of chloride from the plasma and tissue fluids in hypochloraemia, to determine the actual basic requirements in chloride.

For this purpose healthy adults, during rest in bed, were placed upon a salt-poor diet and given additions of sodium chloride when chloride excretion had become constant. On mixed ward diets the chloride excretion in these patients averaged 9 grammes daily. On restriction of the diet to 2.1 grammes of chloride daily the chloride excretion fell within four days to an average of 2 grammes, and remained at this level for three days. Upon the addition of 2 grammes NaCl to the diet the chloride excretion increased by 2 grammes, and upon a further addition of 2 grammes NaCl the chloride excretion increased to an average of 7 grammes. The basal requirement of chloride for this period of deprivation is therefore in the neighbourhood of 2 grammes daily while standard conditions are maintained and perspiration avoided (Falconer and Lyall, 1937a).

Results of Chloride Deficiency

McCance (1936) and his co-workers have made us familiar with the effect of experimental chloride deficiency in the normal adult.

By means of repeated sweating by radiant-heat baths and replacement of fluid by liberal water intake, they succeeded in causing a fall in the plasma chloride to 0.468 mg. per 100 c.cm., an increase in the blood urea to 81 mg. per 100 c.cm., with a reduction of sodium and chlorine of the blood plasma, an increase in the alkaline reserve, and increase in blood proteins. The symptoms experienced were severe, and included anorexia and nausea, lack of appetite, mental apathy, muscular cramps, a general sense of exhaustion, inability to undertake effort, and breathlessness and fatigue on exertion.

The symptoms described by McCance correspond very closely to those found in patients suffering from pathological salt deficiency, of which the commonest cause is pyloric stenosis with repeated and copious vomiting. The patient is drowsy, disoriented, and may be obstructive or violent. He is intensely dehydrated. Table VII shows the blood changes in a typical case, with return to normal values on improvement.

TABLE VII—*Patient aged 66: Pyloric Stenosis*

Date	Blood Urea mg. per 100 c.cm.	Plasma Chloride mg. per 100 c.cm.	Plasma CO_2 vol. %	Plasma PO_4 mg. %
5/12/32	162	408	118	3.1
7/12/32	166	438	92	5.3
8/12/32	150	461	92	4.3
9/12/32	140	480	88	4.0
10/12/32	116	496	—	3.4
12/12/32	114	584	80	—
13/12/32	104	560	72	2.6
14/12/32	78			
17/12/32	64			
3/1/33	35			

In certain instances, if it is found that fluids and saline cannot be replaced efficiently by intravenous medication, it may be necessary to carry out jejunostomy for this purpose (Falconer and Lyall, 1938).

In general, intestinal obstruction at lower levels than the pylorus may result in hypochloraemia, azotaemia, alkalosis, and dehydration if the obstruction is in the upper part of the small intestine; or in azotaemia, dehydration with a variable disturbance of acid-base equilibrium, and no reduction in the plasma chloride (Falconer and Lyall, 1937b). Further variations are possible if fistula is included, as shown by Standard (1938). With duodenal fistula, dehydration and acidosis might actually be produced.

Gastric Chloride Secretion in Pathological States

Since the secretions of the gastric mucosa are reabsorbed normally in lower regions of the alimentary canal, the character of the gastric secretion in pathological states, and particularly during states of hypochloraemia, is of considerable importance in the preservation or restitution of the normal chloride content of the blood plasma and body fluids. Examination of samples of gastric contents taken at random from patients suffering from pyloric stenosis had suggested to us that the gastric mucosa could secrete a juice containing considerable quantities of chloride even when the plasma chloride level had fallen below normal. Suggestive-confirmatory evidence that such was the case appeared in several publications.

McCance (1938) found that there was little change in the hydrochloric acid or total chloride content of the gastric juice during experimentally produced salt deficiency in man. Soley, Lagen, and Lockhart (1938) observed no significant alteration in the free acidity or total hydrochloric acid of the gastric juice during experimental hypochloraemia in three healthy men. Katsch and Mellinghoff (1933) removed quantities of NaCl up to 33 grammes in cases of peptic ulcer, with an average resultant reduction of 51 mg. per 100 c.cm. in the plasma chloride and an average fall of 20 per cent. in the volume of the gastric secretions, but without any appreciable change in the chloride concentration. Nicol and Lyall (1939a) investigated a series of patients suffering from pyloric stenosis and vomiting with severe hypochloraemia. Continuous sampling of the gastric contents over twenty-four-hour periods showed that the daily curves of free HCl, total HCl, and total chloride showed practically no difference from similar samples taken after return of the blood chemistry to normal (Table VIII).

TABLE VIII.—*Average Values of Continuous Samples of Gastric Contents during Hypochlorqemia and Period of Recovery*

Case	Day	Plasma Chloride mg. per 100c.cm.	Gastric Chloride mg. per 100c.cm.	Free Acid	Urine Chloride mg. per 100c.cm.
1	1st	350	628	26	10
	3rd	496	667	30	10
	10th	525	610	26	214
	11th		(gastro-enterostomy)		
	14th	526	635	28	310
	17th	570	680	34	298

The reverse procedure seemed to be necessary to establish this phenomenon with certainty.

For this purpose Nicol and Lyall (1939b) subjected two patients with pyloric stenosis and gastric hypersecretion, but without changes in the blood chemistry, to a similar experimental procedure. The gastric juices were withdrawn continually for periods up to six days when the blood chemistry showed the changes of gross alkalosis and hypochloraemia. Under these circumstances the gastric secretions showed little qualitative alteration, but decreased in volume (Table IX).

This evidence probably does not add much to the clarification of the vexed problem of the regulation of the gastric secretions, but it certainly seems to be clear that

TABLE IX

Case	Day	Gastric Juices			Blood		
		Vol. c.cm.	Chloride	Total Chloride (grammes)	Chloride mg. per 100 c.cm.	Urea mg. per 100 c.cm.	CO_2 vol. %
1	1st	—	—	—	606	36	68
	2nd	4,260	0.707	30	599	40	84
	3rd	2,320	0.628	14.6	526	46	91
	4th	2,080	0.533	11	467	—	98
	5th	1,690	0.595	10	410	68	120
	6th	1,800	0.641	11.5	365	75	130
2	1st	—	—	—	540	28	55

	6th	1,010	0.397	4.0	336	54	102

the secretion of free HCl and chloride by the gastric mucosa is to a large extent independent of and uninfluenced by gross changes in the chloride content and alkaline reserve of the blood plasma. It is difficult to correlate these results with the findings of Apperly and Crabtree (1931) and Browne and Vineberg (1932), and it seems more probable that Gilman and Cowgill (1931, 1933) are nearer the truth when they suggest that the gastric mucosa shows a one-way permeability to chloride and that the chloride concentration of the gastric juice is such as to bring that secretion into osmotic equilibrium with the blood plasma.

Chloride Metabolism in Addison's Disease

During some of the observations already described on the chloride balance in cases of intestinal obstruction, the opportunity occurred to investigate two cases of Addison's disease.

In both the typical blood chemical changes found by Stewart and Rogoff (1925), Baumann and Kurland (1927), and others in adrenalectomized animals, and by Loeb (1933) and his associates in man, were present during the phases of Addisonian crises. One of these patients, however, had been under observation for several years, and although the presence of Addison's disease had been suspected the diagnosis could not be made with certainty until the recognized changes in the blood chemistry appeared. It was obvious that until this time no method was available by which the diagnosis of Addison's disease could be established with any degree of certainty in the early stages. Anderson and Lyall (1937) were struck by the great difference between the rate of urinary chloride excretion found in those cases, as shown in Table X, and in cases of intestinal obstruction with reduction of the plasma chloride levels.

TABLE X

It seemed to us that a method was available for the early diagnosis of Addison's disease from the ratio of the urinary chloride excretion to the plasma chloride level, and we stated that in the absence of evidence of diabetes or renal disease the finding of a chloride concentration in the urine of over, say, 200 mg. per 100 c.cm. when the plasma chloride level is below the minimal normal level of about 530 mg. per 100 c.cm. would strongly suggest the presence of Addison's disease.

Cutler, Power, and Wilder (1938) tested the validity of this suggestion by preliminary investigations on nine subjects with adrenal insufficiency and eight subjects without evidence of disease of the adrenal glands, and later by a standardized procedure in the examination of thirty-six additional subjects —eight with and twenty-eight without evidence of adrenal insufficiency. The test period consisted of three days on a diet containing 0.95 gramme of chloride ion, 0.59 gramme of sodium ion, and 4.1 grammes of potassium, with the addition of 0.033 gramme of potassium per kilogramme of body weight on the first and second days. Blood was drawn at 10 a.m. on the third day and urine collected from 8 a.m. to 12 noon on the third day. Determination of the sodium and chlorine content of the blood plasma and urine showed that "if the concentration of chloride in the specimen of urine on the third day exceeds 225 mg. per 100 c.cm., Addison's disease or adrenal insufficiency is strongly suggested; if it is less than 125 mg., adrenal insufficiency is made unlikely."

Confirmation of the findings of Cutler, Power, and Wilder have accumulated.

Dryerre (1939a) investigated four patients with Addison's disease, five suffering from asthenia not due to Addison's disease, and five normal controls. His results revealed that on the third day of the administration of a salt-poor high-potassium diet the concentration of the sodium in the urine is much higher in cases of adrenal insufficiency than in control subjects. Dryerre did not find the urinary chloride concentration in cases of Addison's disease to differ with such consistency from that of control cases. More recently Dryerre (1939b) has used diminution of the sodium concentration in the urine as an index of response to treatment by cortin and desoxycorticosterone in patients suffering from Addison's disease, and suggests that the method may be of value in standardizing the activity of preparations of cortical extract.

Within the past two years Anderson and I have been investigating patients with some of the signs or symptoms of Addison's disease—weakness, asthenia, pigmentation, hypertension, abdominal discomfort, loss of weight. Our technique differs from that of Cutler, Power, and Wilder, and is more simple.

The patient is given a low chloride diet for a period of five to six days. A shorter period may be necessary. The blood chemistry is investigated at the beginning and end of the period and the urinary chloride concentration compared with the plasma chloride level daily and at the end of the period. The normal ratio of plasma chloride to urinary chloride under these conditions is always greater than 3 to 1. In Addison's disease the urine chloride concentration approaches the blood chloride level, and where the ratio is below 2 to 1 a diagnosis of Addison's disease can be established with certainty.

Summary

This paper indicates the importance of disturbances of chloride metabolism in patients suffering from intestinal obstruction, pyloric stenosis, chronic nephritis, oedema, obesity, hypertension, and Addison's disease.

The exchanges of chloride in the alimentary canal are discussed, both normally and in pathological conditions.

Observations are made on the secretion of urinary chloride in hypochloraemic states, and the changes found in various types of hypochloraemia are illustrated.

It is pointed out that in Addison's disease the reduction in plasma chloride is associated with failure of the kidney to retain chloride.

NOTES ON PSYCHIATRIC CASUALTIES OF THE FIRST DAYS OF WAR

BY

GEORGE PEGGE, M.A., M.R.C.S., L.R.C.P.

Experience of the first two weeks of war indicates that the special stresses of that period have already produced psychiatric cases and problems of special types not usually met with in peace-time psychiatric practice. Though it may be considered premature, it is felt that a record of impressions of such cases should be made while they are yet in mind, particularly as they belong to a phase of the war which is now passed—a period when the much-discussed mass bombardment of civil populations in this country was considered, and appeared to be imminent, before evacuation was completed and before war morale was established.

Occurrence and Attributability to War Strain

A casualty hospital situated close to a great railway terminus in London is so placed as to receive patients who collapse in special circumstances. The glass-domed station, the crowds, loud-speakers, and confusion of curtailed rail services, together with evacuation of children and mothers, punctuated by air-raid-warning sirens, brought the war home to many as a reality for the first time. War morale had not yet been established by leadership, and a sense of security had not been generated by knowledge of what preparations had been made for the protection of the civilian population. In most of the cases the patient had lost touch temporarily with his or her family.

A striking contrast existed between newly precipitated cases and old patients who came up as usual to the psychiatric out-patients' clinic. These old patients were all asked how the present situation affected their symptoms or themselves. Typical replies were: "I don't take no account of that." "I'm afraid this illness makes me rather selfish. I hardly think of the war." A small minority were troubled by fear of air raids, and it may be that others who failed to attend were those most affected.

The newly precipitated cases were brought in ambulances or by the police, having collapsed in the street or the station. On arrival they were still unconscious or confused. It was possible in all cases to restore consciousness and to obtain names and addresses, etc., in a very short time by reiterated reassurance and encouragement, continued until eyes opened and questions were answered. Typically, attention was apt to wander and irrevelant answers were given to questions. In one or two cases there was wild excitability, and this was usually controllable by quiet confident reassurance and persuasion. Only one true hysterical paralysis was seen. As the object of treatment was merely to enable patients to continue their journey out of London or to return them to their homes it has not been possible to follow subsequent developments in most of these cases. In one case a mother taking two children home from the seaside through London collapsed when she became cut off from them in the crowd. In this, as in other cases, there was a large element of fatigue, lack of sleep, and hunger. Alcohol played a part in a number of them, and there seemed to be an abnormal sensitivity to small quantities.

These cases were fairly equally distributed between the sexes. No children were included. They were of the less-educated classes. About twenty cases in all were seen, and the flow diminished markedly after the first week of war.

Cases simulating Acute Onset of Psychosis or of Severe Neurosis

Five cases fall into this class, and all but one were of the professional classes. There were three men and two women. They were doing responsible work and, except in one case, work directly connected with the state of emergency. There were other significant similarities. Four were intellectual types with a high sense of social responsibility; the state of stress had been established for a considerable time before the war broke out, and they had overworked, neglecting their own welfare for that of others, living on snacks and irregular meals and being unable to sleep adequately. In all the fear of a breakdown had been a factor for some time and had been compensated by increased press of activity, mental and physical. In all the onset was sudden and dramatic.

A man of 30 in a very responsible job calling for speed of decision and acuteness of judgment suddenly lost all energy, and after wandering aimlessly for an hour or so had a "black-out" of consciousness without collapsing. He was brought to hospital ten hours later with symptoms suggestive of paranoid schizophrenia.

A highly conscientious overworking governess of 28 had had sole charge of four small children in the country. She came up to London, losing some trunks on the way. The sight of sand-bagged buildings and the dark night streets seemed to alarm her unduly, and she suddenly said she must go out at once and find a job. She ran into the street and was eventually found in a police station. Two hours later, when seen at hospital, she was wildly frightened and suspicious, believing that a plan existed for her destruction in which the physician was a tool of the Government. She slept well with 15 grains of medinal, but next day was still more frightened and suspicious, and had to be placed in a mental hospital under an urgency order.

A medical man doing important organizing work on night duty had almost complete insomnia for a week and showed obsessional doubts and other obsessional symptoms.

A V.A.D. nurse who had served four and a half years without breakdown during the last war and who had attempted the same standards, disregarding twenty years' advance in her age, had suddenly what was probably a hysterical attack. There were, however, some persisting organic signs, which put the diagnosis in some doubt.

A young postman of 22, of good physique, was seen in a state of acute terror with loss of social sense and all morale, sweating, pallid, and with dilated pupils and crouching posture. He showed regressive tendencies, and passed water in public without recognizing that such an act was unusual. He was not amenable to reason or suggestion, though occasionally unexpectedly he would obey a suggestion. He became a little calmer on taking a sedative, but remained confused and frightened to an extreme degree. Subsequently he was admitted to another institution and failed to improve, regressing further in spite of convulsion therapy.

The severe and dramatic onset and typical symptomatology of this group of cases are in some instances markedly in contrast to the subsequent history. All were removed from the situation of stress and received various forms of treatment, the details of which are not available, but in which rest and sedatives certainly played a large part in most instances. The patient with obsessional symptoms recovered completely and is to return shortly to duty. One of the "paranoid schizophrenics" after three weeks is reported to be well and returning to duty. The other is as yet no better, but has been under care for less than a week. The case diagnosed as "simple terror" had developed more marked schizophrenic katatonic features. The outcome in the V.A.D. nurse is still in doubt, but recovery and return to duty appear probable.

Conclusions

Diagnosis and particularly prognosis in the second group of patients are particularly difficult. The typical features are the high sense of social responsibility adding to the stress of circumstances upon the patient before the onset of the breakdown, and the florid psychotic or neurotic symptoms at the time of breakdown. The outcome of these cases is not clear, but it is suggested that quick recovery is probable in a large proportion. They may easily be confused with true psychoses of acute precipitation. The possibility of relapse cannot as yet be ruled out. The simple cases in the first group are of more purely hysterical and anxiety types, though in the patients seen the hysterical symptoms were still plastic and amenable to suggestive modification. The probability of relapse would seem to be great. In most cases fatigue and neglect of proper meals have been large factors in the precipitation of the condition—factors that are easily removed if the patient can be got away from the situation of stress. Insomnia in some degree has been almost universal before the breakdown.

I have been engaged in diagnosis and disposal and have not had first-hand experience of subsequent treatment, but in view of the rapid recovery of some patients with simple rest away from stress it is to be hoped that the adoption of such methods as convulsion therapy will be delayed until the possibility of rapid spontaneous recovery has been ruled out. The fact that in the first week of war admissions to the observation wards of London County Council hospitals were much in excess of normal would tend to confirm the suggestion that many cases were wrongly diagnosed as psychoses, for it is well known that the great war and the war in Spain did not materially increase the incidence of insanity.

Summary

Two main types of psychiatric cases seen at a casualty hospital since the declaration of war are described:

The first type occurs in those of less strongly established sense of social responsibility and usually of less education. Both sexes are equally affected.

The second type occurs in highly intelligent, highly responsible people of both sexes.

The alarming, often psychotic, symptoms of the second group are not easy to distinguish from true psychoses. The diagnosis and prognosis can only be made after an initial period of treatment.

Cases in which the neurosis was established before the outbreak of war are, so far, in many instances quite unaffected by war stress.

DIABETES AND KIDNEY FAILURE

BY

K. E. BARLOW, M.R.C.S., L.R.C.P.

Medical Registrar, Coventry and Warwickshire Hospital

The following two cases of concomitant diabetes and nephrosclerosis are recorded in relation to some interesting questions of renal physiology.

Case I

On February 8, 1939, a man aged 56 was admitted to the medical wards of the Coventry and Warwickshire Hospital complaining of his right knee, which was painful and swollen. Three and a half months before admission the swelling had come on acutely in about three hours, and had persisted without remission. Radiographs showed punched-out areas on the external aspect of the right femoral condyle at the junction of the articular and external surfaces and in the part of the tibia which lies immediately adjacent. A radiological diagnosis of gout was suggested. Blood uric acid was estimated at 3.8 mg. per 100 c.cm.

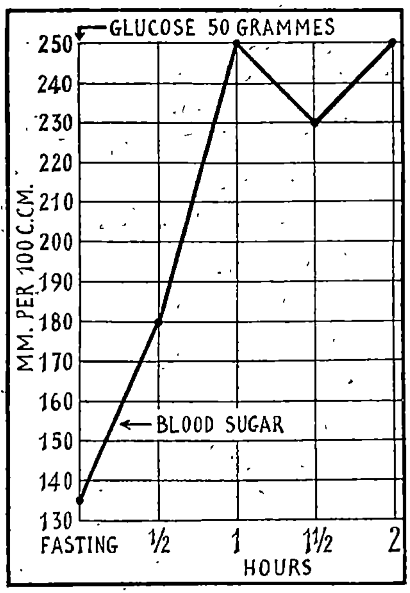

Chart 1.—Case I. The glucose-tolerance curve. Sugar was present in all specimens of urine.

Apart from the present trouble with his knee the patient had always considered himself a healthy man, although he said that he had had diabetes for about seven years. His urine turned Benedict's solution green. Investigation of the blood showed a diabetic sugar tolerance (Chart 1). As the patient looked pale, a blood count was made. Red blood cells were found to be 3,525,000, with haemoglobin 74 per cent. Free hydrochloric acid was present in the stomach, although reduced, and the icterus index was 6 units. This implied a haemopoiesis which was deficient but not characteristic of pernicious anaemia.

The routine examination of the urine revealed albumin. The blood pressure was 190/120. The retina showed haemorrhages but no exudates. The specific gravity of the urine passed on waking was consistently lower than that of specimens passed later in the day: the usual reading was of the order of 1012. A twenty-four-hour specimen of urine revealed a polyuria of 91 oz. Blood urea nitrogen was estimated at 28.9 mg. per 100 c.cm. Questioned about his condition before admission, the patient stated that he was accustomed to feeling thirsty but that "he fought against it." Usually he passed urine in the night, and he thought that the amount might be between one and two pints.

Commentary on Case I

The presence in the same patient of kidney damage and diabetes raises some interesting questions of renal physiology. The typical dysfunction of nephrosclerosis is failure of urinary concentration: a large volume of urine of low specific gravity is passed. Diabetes, on the other hand, tends to produce a large volume of urine of which the specific gravity in the uncontrolled disease is high, due to the sugar content. Typically the concentrating power of the kidneys is good in diabetes. What is the effect upon the mechanisms of sugar excretion in a diabetic of a kidney in which the powers of concentrating urine are damaged by nephrosclerosis?

Current views of renal physiology describe a glomerular filtration with later concentration by the tubules. Considered as a physical process, filtration implies the passage across the filter of a solution equivalent in concentration to that of the blood. If the glomerulus is a simple filter, the sugar level of the glomerular filtrate should rise and fall with the level of the sugar in the blood. This appears to be Cushny's view. The assumption follows that the renal threshold is to be looked for in the functions of reabsorption and concentration (which are attributed to the tubules), since refusal to filter and the ability to concentrate are not the properties of an ordinary physical filter. In diabetes it is to be assumed that water and threshold substances are withdrawn from the glomerular filtrate and returned to the blood, leaving the post-tubular urine concentrated and of correspondingly higher specific gravity.

From this argument it follows that where the kidney function of concentration is damaged the sugar leakage should be increased. If the glomerular filtrate contained a sugar concentration equivalent to that of the blood, and if the renal threshold depended upon the function of concentration of urine, damage to this function should lower the renal threshold to sugar and increase the degree of glycosuria.

The case above recorded offers a critical experiment upon this point. The glucose-tolerance test shows that a lowering of the renal threshold does in fact result from the kidney damage. Glycosuria occurs at a blood-sugar level of 146 mg. per 100 c.cm., although at the end of two hours the blood sugar remains high (224 mg.). The conclusion is that dysfunction in urinary concentration does lower the renal threshold to sugar. This fact is of importance in the interpretation of glycosuria in diabetics suffering from kidney damage. In such patients sugar in the urine may correspond to blood-sugar levels of much lower and more normal character than is usual in diabetes.

If this be accepted, however, a further question arises. 140 mg. of blood sugar per 100 c.cm. is a level within the limits of what may result from a large carbohydrate breakfast. This being so, why is it that nephrosclerotics do not commonly produce a glycosuria as a sort of "renal leak" induced by dysfunction of urinary concentration? It appears that some factor other than failure of concentration and reabsorption must be at work in diabetics to produce a glycosuria from low blood-sugar levels, since this does not occur in uncomplicated nephrosclerosis.

Case II

In attempting to confirm these views a second case was investigated. A woman aged 67 was admitted on February 26, 1939, complaining of breathlessness, pain in the chest, swelling of the ankles, and retching. The oedema of the ankles had been present twelve months, but was getting worse. Breathlessness dated back fourteen days. Blood pressure on admission was 160/95. This rose to 200/110 after three weeks, when the oedema had cleared. A previous diastolic reading of 120 mm. Hg had been recorded some months previously. A history of polyuria was elicited; the patient stated that she was accustomed to pass water about three times during the night, and she estimated the quantity at three pints. The urine contained albumin. At the time of admission extensive oedema was present. Blood urea nitrogen was estimated at 51.8 mg. per 100 c.cm.

These findings suggested a case of nephrosclerosis passing into uraemia. The need for the immediate use of diuretics vitiated measurements of twenty-four-hour urinary volumes and of specific gravity. The history of polyuria, however, is evidence of long-standing failure of renal concentration, particularly as albumin had been present in the urine six months previously.

The patient stated that she had suffered from diabetes for fifteen years. Her urine turned Benedict's solution green. The blood-sugar curve is shown in Chart 2.

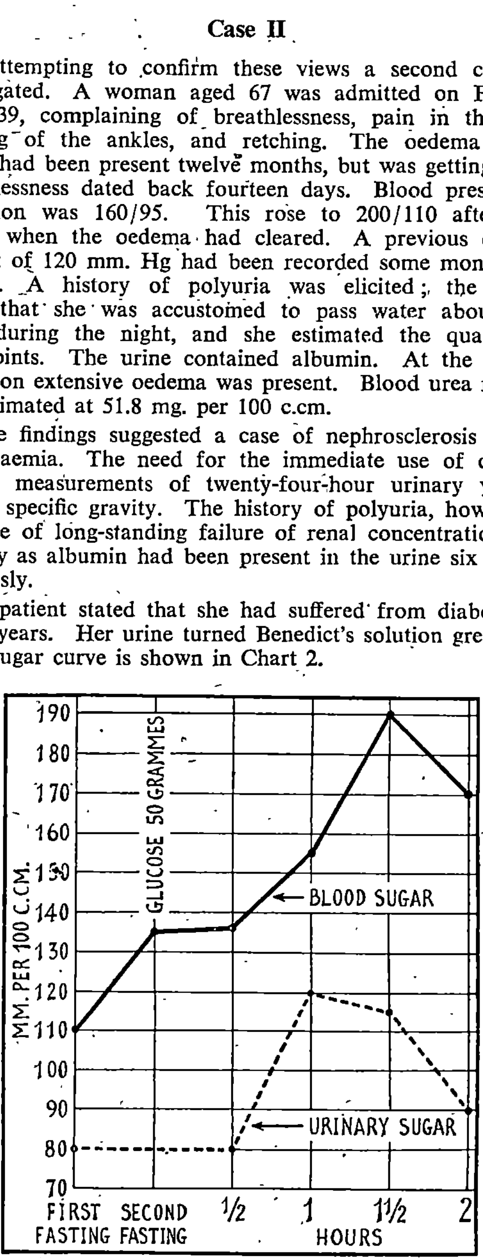

CHART 2.—Case II. The glucose-tolerance curve, showing blood-sugar and urine-sugar levels. Ketones were present in the first four specimens of urine.

Commentary on Case II

The effect of the kidney damage upon sugar excretion is shown by the glucose-tolerance curve. Here to verify results an extra blood-sugar estimation was carried out an hour before the tolerance test, and the bladder was then emptied by catheter. This investigation showed that from a fasting blood-sugar level of 111 mg. per 100 c.cm. the patient was passing 85 mg. per 100 c.cm. of sugar in the urine. The renal threshold therefore was below 110 mg. One hour after 50 grammes of glucose had been ingested the blood sugar had risen to 154 mg., and urine obtained half an hour after this specimen showed 120 mg. per 100 c.cm. The blood-sugar level rose to 184 mg. in one and a half hours, and remained at 168 mg. at the two-hourly interval.

These results show that the renal threshold to sugar had been lowered by the kidney damage to a level suggestive of a "renal leak." That this is not the explanation is evidenced (1) by the diabetic lag which gives a blood-sugar level of 184 mg. per 100 c.cm. in one and a half hours and 168 mg. at the end of two hours; (2) by the presence of ketosis in the urinary specimens, revealing a deviation of fat metabolism.

This case therefore confirms that where diabetes and nephrosclerosis coexist the urinary findings in respect of sugar represent a different physiological state from that which obtains in ordinary cases of diabetes uncomplicated by nephritis. In uncomplicated diabetes the same degree of glycosuria represents a profounder disturbance of the *milieu* of the tissue cells than obtains in cases complicated by nephritis. The logical conclusion is *that, so far as the diabetes is concerned,* the mild diabetic is better off with nephritis than without it. Whether this supposition is borne out in experience time and observation will reveal.

The evidence of this investigation has obvious bearings on insulin therapy. In uncomplicated diabetes, glycosuria may be taken as evidence of a raised blood-sugar level which may require to be lowered by insulin. In the nephritic, glycosuria has not the same significance. It is likely to be present in cases in which the blood sugar is not raised to a degree likely to be toxic to cell function, and if insulin were to be pushed in these cases, under the guidance of urinary glucose, it seems probable that dangerous and even destructive hypoglycaemia might be induced.

Summary

Two cases are recorded in which diabetes and nephrosclerosis coexisted.

A theory is offered that may explain the fact that the diabetic with nephritis often does surprisingly well.

The conclusion is drawn that the mild diabetic is better off with nephritis than without it.

I wish to express my thanks to Dr. A. J. Wilson for permission to report his cases and to Dr. Wright for the assistance of his department in the sugar estimations.

Evaluation of Disinfectants.—It is proposed in two papers by different authors (whose results do not agree) that disinfectants intended for clinical use should be submitted to tests of toxicity for mammalian tissue as well as tests of capacity for killing bacteria. The method employed by Bronfenbrenner *et al.* is to determine the diminution in oxygen uptake by both a bacterium and a suspension of mouse liver caused by exposure to various concentrations of the disinfectant. Salle and his colleagues, on the other hand, employ the older method of comparing a phenol coefficient obtained in the ordinary way with the results of exposing tissue cultures to the action of the disinfectant.—Evaluation of Germicides by Manometric Method. J. Bronfenbrenner and J. Doubly. Evaluation of Group of Germicides by Tissue Culture Technique. A. J. Salle, W. A. McOmie, I. L. Shechmeister, and D. C. Foord.—*J. Bact.* June, 1939, **37**, 583, 639.

Clinical Memoranda

Simultaneous Colles's Fracture and Backward Dislocation of the Elbow

The following case would seem to be of interest in view of its rarity. Usually when a fall on the outstretched hand results in a Colles fracture, this happening absorbs much of the force of impact. Further, the victim "crumples up," thus preventing any continuation of rigidity at the elbow-joint which is necessary to allow transmission of force to the lower end of the humerus as a fulcrum for dislocation.

Case Report

A healthy undergraduate aged 21 was running down the stone steps of an underground lavatory on May 20, 1939, about 10.30 p.m., when he slipped and fell heavily on his outstretched left hand. He walked back to his college in great pain at the wrist-joint and elbow-joint, and with a useless left arm. After first aid had been rendered he was taken to the Evelyn Nursing Home.

On examination the left wrist showed the classical "dinner-fork" deformity, and a Colles fracture was evident; the left elbow showed considerable deformity, the olecranon projecting backwards, and the ordinary signs of dislocation. A general anaesthetic (evipan and chloroform and ether) was given, and reduction was effected by manual traction and manipulation at each joint, starting with the elbow. The wrist was put up in a non-padded "castex" cast, after the pattern of Böhler. "Castex" has a celluloid instead of a plaster-of-Paris basis, and is extraordinarily light, therefore encouraging function. The elbow was bandaged over plenty of wool and placed in a sling. One-quarter grain of morphine was ordered. The *x*-ray report by Dr. E. V. Bevan next day (May 21) stated that the position of the fragments at the wrist was perfect, and that there was a tiny fragment torn off the coronoid process of the ulna. The usual considerable swelling developed (arm, one and three-quarter inches; forearm, two inches).

After-treatment.—It was impossible to get the patient to carry out the modern (wrist) treatment of immediate full use of the hand and fingers because of the tremendous bruising and swelling involving the origins of the forearm muscles. Any attempt to use the fingers during the first week or two caused great pain and inhibition. Progress in function of the wrist was therefore slowed up very greatly. Conversely, this relative stagnation of activity and circulation in the forearm muscles undoubtedly held up the absorption of the extravasation from the neighbourhood of the elbow-joint, as it tended to track distally. Radiant heat and massage were given, and *active* movements encouraged at the elbow-joint.

On *June 13* all swelling had disappeared, but movement at the elbow was very restricted—flexion to just over 90 degrees and extension limited by about 40 per cent. The "castex" was removed from the wrist, and strapping with elastoplast, reinforced by split-tailed "paragon" plaster, was substituted. The movements were good, but not full, and slight swelling was present.

On *June 19* flexion of the elbow had improved to about 90 per cent. normal, but extension was still restricted by 30 degrees. The strapping was removed from the wrist, which was still a little "puffy"; the movement was not quite full.

Commentary

This state of things at the end of a month contrasts forcibly with the usual *full* function and *normal* appearance of the ordinary Colles fracture attained by Böhler's methods. It is in still greater contrast with the normal progress of a dislocated elbow unhampered by a broken wrist and allowed the effect of forearm function. I recorded a case in the *Journal* (1935, **1**, 15) of a

Cambridge scrum-half who played rugger and gained his "blue" in this important key position of accurate passing nineteen days after backward dislocation of the elbow uncomplicated by other injuries.

Apart from the coincidence of the double injury, therefore, it would appear that each lesion delays the recovery of the other, and that restoration of full function of either joint is considerably postponed thereby.

Bell's Palsy treated by Incision of Sheath of Facial Nerve

The following case may be considered of sufficient interest to warrant publication.

Case Record

A boy aged 13 was referred to me early in November, 1938, on account of a Bell's palsy of two weeks' duration following a cold. There had been intermittent slight otalgia on the affected side. Upon examination it was found that left-sided facial paralysis was complete. There was very slight hyperaemia of the tympanic membrane with slight mastoid tenderness. The patient, who was and remained afebrile, was treated for two weeks by conventional local and general therapeutic means. As there was no evidence of improvement in the paralysis, and as the existence of Wallerian degeneration was proved by the absence of response to faradic stimulation, the nerve was exposed in the Fallopian aqueduct by means of small chisels and bone curettes from the mastoid foramen to its forward bend beneath the lateral semicircular canal. The sheath, which appeared normal, was slit up with the point of a Graefe cataract knife for the same distance. The manner in which the ostensibly hyperaemic nerve protruded through the slit sheath offered immediate and striking proof of the compression to which the inflamed nerve was being subjected.

The wound healed by primary union. The patient left hospital on December 6, at which time faradic response was still absent, though the tone of the facial muscles seemed to have improved. When next seen on February 8, 1939, the facial paralysis had quite recovered and the hearing was normal.

The late A. B. Duel, in two special lectures delivered at the Royal College of Surgeons on October 10 and 11, 1934, stated that from 15 to 20 per cent. of cases of Bell's palsy underwent a violent toxic infection with a severe inflammatory reaction (a compression within the Fallopian aqueduct) which renders the axons useless; in a day or two faradic response disappears. In such cases the regeneration is never complete, the amount of recovery bearing a definite relation, as in the cases of accidental or traumatic origin, to the severity of the initial lesion.

Arguing on the success which attended his experiments on rhesus monkeys in which the nerve was exposed and injured, Duel and his co-worker, the late Sir Charles Ballance, maintained that the cases of Bell's palsy which make but a partial recovery ought to have the nerve in the Fallopian aqueduct uncovered early and be decompressed by incision of the sheath *at that stage.* He further maintains that careful attention to the electrical responses will allow of differentiation between the simple potentially recoverable cases and those which are violent and in which partial or complete paralysis will persist. Duel and Ballance corroborated their theoretical and experimental work by the brilliant results they obtained in practice, in one case of palsy of ten years' duration.

The operation was done in the case described above because clinically it belonged to the smaller percentage of "violent" cases.

Reviews

IMPAIRED FERTILITY

Sterility and Impaired Fertility: Pathogenesis, Diagnosis, and Treatment. By Cedric Lane-Roberts, M.S., F.R.C.S., F.R.C.O.G.; Albert Sharman, M.D., M.R.C.O.G.; Kenneth Walker, F.R.C.S.; B. P. Wiesner, D.Sc., Ph.D., F.R.S.Ed. With a Foreword by Lord Horder, G.C.V.O., M.D., F.R.C.P. (Pp. 419; 87 figures; 3 plates. 14s. net.) London: Hamish Hamilton. 1939.

Sterility and its treatment has in the past received scant attention in most gynaecological textbooks, and the inquiring reader has had a difficult task to obtain a comprehensive view of modern work on this subject. This new publication by eminent workers in this country supplies a real need. A much larger field is covered than is indicated by the title, for almost every aspect of reproductive physiology in the human species is discussed. A considerable amount of space (116 pages) is devoted to the methods of examining seminal fluid, and, as is to be expected, Dr. Wiesner's methods for distinguishing spermatozoal abnormalities are described at length. Special attention has also been given to the technique of testing for tubal patency, and there is a full discussion with numerous illustrations of the newer methods of salpingography. The technique of endometrial biopsy is excellently described, and many less usual topics, such as testicular puncture and artificial semination, receive full attention.

In compiling a book on such a large subject it is perhaps inevitable that there should be a certain amount of overlapping between the sections. This is most noticeable with regard to endocrinology, and particularly so with regard to the gonadotrophic hormones. The authors have adopted various combinations of letters to express the nature of the hormone preparations for clinical use: thus extract of the anterior lobe of the pituitary gland is designated "ALP." This title has an awkward resemblance to "APL," which has hitherto been commonly used by American writers to describe an entirely different preparation. In spite of recent official recommendation the adjective "gonadotropic" is used in preference to "gonadotrophic"; and it seems that the respectable compound word "non-ovulation" must give way to the doubtful hybrid "anovulation." The sections on hormone treatment are somewhat discursive, and are written in an enthusiastic rather than a critical manner; better results are implied than the authors' own figures seem to justify. Statements without statistical backing such as "the administration of chorionic hormone is, as a rule, successful in preventing abortion" are not helpful. Appendices are added in which biological tests are described, and technical details concerning the preparation of certain gland extracts are enumerated. The book is lavishly illustrated and the reproductions are of a high order. We can confidently recommend this publication as an up-to-date exposition of modern work on human reproductive physiology and particularly of the problems connected with impaired fertility in the male and female.

ARTERIAL EMBOLISM IN THE LIMBS

Les Occlusions Artérielles Aiguës des Membres: Formes Cliniques, Indications Physiopathologiques et Thérapeutiques. By H. Haimovici. (Pp. 124; 26 fr.) Paris: Masson et Cie. 1939.

This book follows the author's monograph on arterial embolism in the limbs which we reviewed last year. Unlike that work, which dealt largely with the experimental and pathological aspects of peripheral vascular occlusion, the present volume is not illustrated, and is more concerned with the clinical and therapeutic features. It also covers a wider field inasmuch as arterial obliteration by causes such as injury and inflammatory lesions is considered as well as that due to embolism. Professors René Leriche and J. Fiolle wrote a preface to the former volume, Professor Fiolle introduces this one. It worthily maintains the high standard of the former work and does credit to the Faculty of Medicine of Marseilles, which, along with the Strasbourg School headed by Leriche, is achieving a reputation for its contributions to our knowledge of occlusive vascular disease.

This book consists of six chapters, the first dealing with physiopathological considerations, the second with the syndrome of acute arterial occlusion, while the remainder consider in turn clinical features, diagnosis, prognosis, and treatment. Difficulties in distinguishing between arterial occlusion the result of embolism and that due to thrombosis are considered in detail. When the result of embolectomy is doubtful or when for technical reasons this operation is not feasible, Haimovici advocates arteriectomy, but treatment by drugs, vascular exercises, injection of the sympathetic ganglia, and the indications for amputation are also considered. The six chapters are divided into conveniently arranged and well-headed sections and follow a short general introduction in which the scope of the work is indicated. References are scarce and neither listed nor given in detail; there is no bibliography and historical aspects are not considered. The absence of illustrations has already been commented upon, but these are defects in an otherwise excellent account of the subject. Clinicians generally and surgeons in particular should be familiar with this work dealing with a subject which we in this country have perhaps tended to neglect.

IMMUNOLOGY

Immunity: Principles and Application in Medicine and Public Health. By Hans Zinsser, M.D., John F. Enders, Ph.D., and Le Roy Fothergill, M.D. Fifth edition of *Resistance to Infectious Diseases.* (Pp. 801. 28s. net.) London: Macmillan Company. 1939.

The last twenty years have seen a great increase in the application of immunological knowledge to medicine and public health. At the same time the work with synthetic antigens, largely initiated by Landsteiner, and the quantitative work of Heidelberger have made antigen–antibody reactions much more comprehensive. In order to aid the practitioner to understand more fully methods used in practice in the light of the new theoretical knowledge, and to stimulate laboratory workers by examples of the practical application of their work, Professor Zinsser, with the co-operation of Drs. Enders and Fothergill, has re-written *Resistance to Infectious Diseases* under a new title. It is now divided into two sections—"Principles and Theory" and "Special Immunological Problems of Individual Infections."

The second section contains thorough discussions of, for example, immunization against diphtheria, the serum treatment of pneumonia, and the immunological aspects of virus diseases and of scarlet fever and streptococcal infections. The first section is unequal. There is a full treatment of hypersensitiveness, the practical significance of which appears particularly in the chapter on tuberculosis. There is a very good account of iso-antibodies and blood groups. The treatment of the relation of the specificity of antigens to chemical structure is clear and thorough; but the treatment of precipitation and agglutination reactions seems inadequate. There is little about the antigenic structure of bacteria; little also about the permanent effect of one immunization as shown by the prompt appearance of large amounts of antibody in the serum on a later injection of antigen. It is also regrettable that a book of this type should perpetuate the error of speaking of the two fractions into which serum proteins are separated by dilutions of serum with distilled water as the globulin and albumin fractions. The index is more than usually annoying; thus, if the reader looks up "Arthus phenomenon" he is referred to hypersensitiveness, and then has to look through a column of references to hypersensitiveness before arriving at "Arthus phenomenon."

THE TISSUES OF THE BODY

The Tissues of the Body: An Introduction to the Study of Anatomy. By W. E. Le Gros Clark, F.R.S. (Pp. 372; 109 figures. 15s. net.) London: Oxford University Press. 1939.

This work by Professor Le Gros Clark is the type of book which for a long time has been desired by teachers of anatomy. It embodies a large amount of information which has been acquired during the last ten or fifteen years and has not yet been adequately recorded in general textbooks. This material has been put together in a succinct form, accompanied by valuable comments and references to the articles in which the subjects were originally described. Beginning with a brief reference to the anatomy of the cell and early development of the human embryo, there follows a description of the connective tissues, including cartilage and bone, in which allusions are made to the recently described cartilaginous canals in the epiphyses of long bones and the vascularization of articular cartilage. This is succeeded by a chapter on the structure and growth of bone, illustrated by coloured photographs of madder-fed pigs, and diagrams showing the manner in which bone is remodelled by the combination of growth processes with an absorption mechanism which preserves the contour of the bone. A review is also given of the biochemical factors involved in the deposit and absorption of lime salts, the effects of certain enzymes circulating in the blood, and the evidence afforded by *x*-ray films of permanent condensations in long bones, which mark the original site of the epiphyseal lines during temporary arrests of growth, these condensations having occurred during childhood as a result of illnesses of a febrile nature. The chapter on blood vessels is especially noteworthy; it includes a summary of the important work on the growth and innervation of blood vessels by Clark and Clark, who have perfected a means of direct observation of the growth of capillaries and circulation of the blood in a transparent chamber inserted into the ear of a rabbit. Two camera lucida drawings of these are reproduced: one shows two separate *non-anastomosing* lymphatic and blood vessel plexuses within the same field; the other records of the growth of a lymphatic capillary towards an extravasation of blood and the subsequent picking up of red corpuscles by the newly formed lymphatic sprouts and wandering cells.

Later the author reviews the observations and deductions of Boeke, Head, Stopford, Waterston, and Woollard on the innervation of the skin, and he then discusses the cerebrospinal and sympathetic nervous systems partly from the historical standpoint, partly from the experimental, physiological, and morphological aspects. The latter group includes references to chromatolysis, cell atrophy, retrograde cell degeneration, allusions to the older methods of Wallerian and Marchi degeneration, and observations on the degeneration of "terminal boutons" and nerve endings. Finally there is a review of recent work on the vascular supply of the central nervous system, comprising observations on the relative vascularity of different parts of the brain; the intracranial circulation; the effects on the circulation of nervous activity; the disposition and closeness of the capillary plexuses, their relation to the nerve cells and particularly to cell collections in the hypothalamus.

With reference to the subtitle of this work we may confidently state that it will be read with interest and profit by many besides those students of anatomy to whom the author offers it as an introduction.

SURGERY AND RHEUMATIC DISEASES

Der Rheumatismus. Chirurgie und Rheumatische Krankheiten. By Dozent Dr. A. Fonio. (Pp. 235; 26 figures.) Dresden and Leipzig: Theodor Steinkopff. 1939.

In this small volume Dr. A. Fonio of Berne summarizes our knowledge of rheumatism and the so-called rheumatic diseases. An account of the clinical manifestations presented by acute and chronic rheumatism in different parts of the body, their differential diagnosis, and the hypotheses that have been advanced to account for the so-called rheumatic diseases comprise the bulk of the work. Some idea of its scope may be gathered from the fact that there is a special section on haemophiliac joints, and that such conditions as tenovaginitis stenosans, von Bechterew's spondylitis, and the different varieties of osteochondritis are dealt with in detail, while reference is also made to such affections as Morton's metatarsalgia and prepatellar bursitis. The difficult problem of the relation of tuberculosis to rheumatism is discussed in some detail. There are twenty-six illustrations, mostly of radiographs showing the osseous changes in such conditions as Kienboch's disease and Calvé-Legg-Perthes osteochondritis.

The illustrations break up pages of well-printed text, which is clearly set out under appropriate headings. A list of the source of references from which the text has been compiled is given and occupies three pages, but a more complete bibliography to an otherwise very fully discussed subject might be advisable in a second edition. Author and subject indexes are provided. This is altogether an admirable work which is worthy of translation into English.

Notes on Books

The third edition of Dr. DOUGLAS KERR's well-known textbook, *Forensic Medicine*, has been enlarged to include consideration of the effects of several Acts of Parliament, notably the Matrimonial Causes Act, 1937, and the Infanticide Act, 1938. He has rewritten the section on professional secrecy at the beginning of the book with relation to pregnancy, confinement, abortion, attempted suicide, venereal disease, crime, and other matters: his attitude is substantially that professional secrecy should be maintained except in extreme cases where the public interest demands a disclosure. Considering that the book is largely intended for students, it would be improved by an amplification of the sections dealing with civil aspects of the subject, or medical jurisprudence proper—for example, testamentary capacity, business relationships, negligence, consent, and the liability of hospitals. The inclusion of the subjects of criminal and civil negligence in the chapter on wounds still seems incongruous with all respect to the author's justification of their inclusion there for teaching purposes. The book remains an admirably clear and useful presentation of a wide subject for those who are not immediately concerned with it. It is published at 15s. by A. and C. Black.

The Language of the Dream by Dr. EMIL A. GUTHEIL is published at 15s. by the Macmillan Company. It contains a wealth of examples of dreams, the interpretation of which illustrates the personality of the dreamer especially in relation to neurosis. The author is a disciple of Steckel and claims that it is possible to build up a "language of dreams," since the symbolization employed in dreams is essentially restricted. He believes that much of the free association of patients in relation to dreams enjoined by Freud is a waste of time and indeed in many cases misleading. He claims that the method of "active analysis" in which the analyst does the interpretation is time-saving and successful. In so doing he does not use a rigid interpretation of symbols, but, knowing that the possible meanings of symbols are few, he is able from knowledge of other factors relating to the patient and by comparison with other dreams to pick out the real meaning for the particular patient without much difficulty. He considers that other schools of psychopathology have recently neglected the dream and that in any case their approach is one-sided. The author certainly makes out a case for his slogan of "back to the dream" and shows how it often illustrates both the life plan of the patient and his principal difficulties and resistances. The book is readable and logical in its arrangement and will certainly stimulate thought among all those interested in psychopathology and psychotherapy.

Preparations and Appliances

A NEW TYPE OF COMBINED OBSTETRIC COUCH AND DELIVERY TABLE

Professor CHASSAR MOIR, M.D., F.R.C.S.Ed., F.R.C.O.G., writes from the Nuffield Department of Obstetrics and Gynaecology, University of Oxford:

An obstetric couch should combine three distinct features. It should be a bed of reasonable size and comfort; it should be instantly convertible to an operating table for the lithotomy position, and it should have an easy means of lowering the head end for treating a shocked patient. In this country an additional problem of design is presented by the fact that it is customary to conduct normal deliveries with the patient in the left lateral position; a bed of unusual breadth is therefore generally required; but, as will be seen, this difficulty can be overcome by a simple alternative arrangement which avoids the necessity of pulling the patient into a cross-bed position.

The details of a new type of combined bed and operating table and its method of use are clearly shown in the accompanying pictures. The bed is absolutely rigid and has no tendency to slide on the floor. The head rail can be removed for convenience to the anaesthetist. The height is convenient both for normal delivery and for forceps application with the patient in the lithotomy position. When the lower portion is pushed in much less room is taken up than with an ordinary bed, and the new couch is therefore specially useful where space is restricted. Lastly, while this bed is not designed as an operating table for laparotomies, it can, in point of fact, be put to this purpose. On several occasions circumstances have made it necessary to use the couch for performing Caesarean section, and although it is unnecessarily broad for the purpose (3 feet) no undue difficulty is experienced by an operator of average height. For abdominal operations the slight Trendelenburg tilt can be used to great advantage. Before starting the operation, however, it is advisable to place a small support, such as a builder's brick, under each of the two lower legs; the degree of tilt available is then considerably increased.

This bed has been developed in the Nuffield Department of Obstetrics and Gynaecology and has been in use in the maternity wards of the Radcliffe Infirmary, Oxford, for nearly a year. It has proved to be a great boon to both the medical and nursing staffs, and in particular it has been welcomed by the labour-ward sisters because of the help it gives in conducting delivery in the left lateral position. As will be seen, certain features found in other obstetric beds have been borrowed and combined with new ideas. My thanks are due to Mr. Carnac Rivett for allowing me to copy his pattern of leg support for left lateral deliveries. I am greatly indebted to the generous help of Mr. H. R. Hoskins, who has been responsible for putting the design into practical form. The bed is made by Messrs. Hoskins and Sewell, Ltd., Midland Works, Bordesley, Birmingham. I have no financial interest in its manufacture or sale.

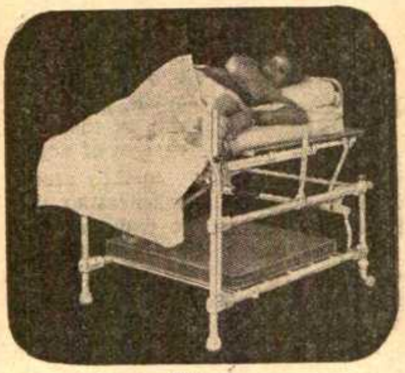

Fig. 4.

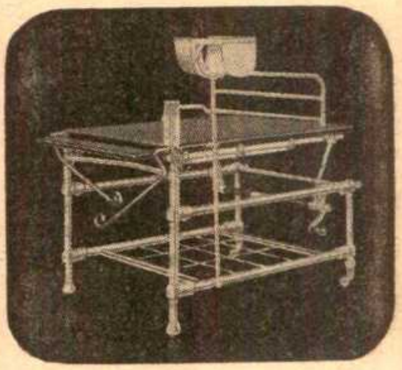

Fig. 5.

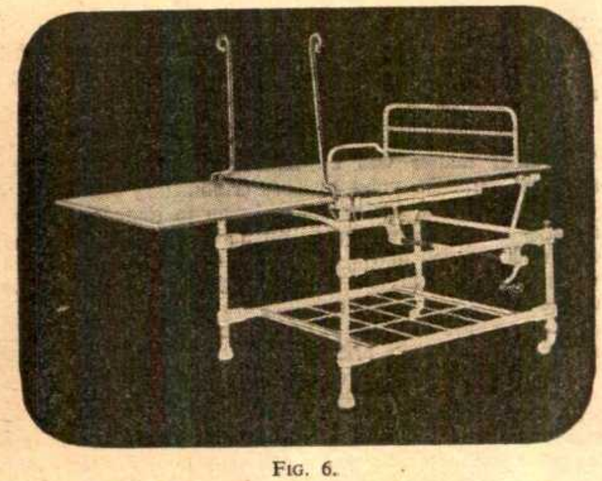

Fig. 6.

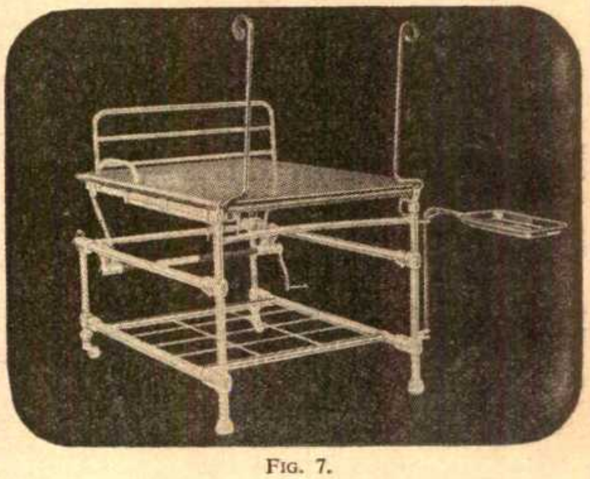

Fig. 7.

Fig. 1.—Normal position of bed. The castors on the legs at the head end allow the bed to be easily moved when the labour room has to be cleaned. The head-rail can be detached for convenience if an anaesthetic is to be administered.

Fig. 2.—By turning the handle the bed can easily be put in the head-down position for treating shock.

Fig. 3.—For left lateral delivery a foot support is dropped into slots and the lower section of bed is pushed into a convenient position. (See also Fig. 4.) Note the pillow-retaining rail at right side of bed.

Fig. 4.—Position for left lateral delivery. Note that the lower section of the rubber mattress is now accommodated on a shelf below the bed.

Fig. 5.—During the actual delivery the patient's upper leg is supported on a cradle.

Fig. 6.—The preparation for lithotomy position can be made by a nurse single-handed. The lower section of the rubber mattress is removed as before. The supports for the legs (which are permanently attached to the bed) are swung round into the upright position, and the patient's legs are raised and secured in the usual manner.

Fig. 7.—Finally, the lower section of the bed is pushed in. The obstetric couch has now become an operating table. There is ample room for a bucket to be placed below the bed, and there is no obstructing metal work to be soiled with blood, etc. The small instrument tray may be attached to the side of the bed, on which can be arranged the instruments necessary for perineal repair. Even when dealing with a heavy patient all manœuvres can be performed by one nurse.

MATERNITY HOSPITALS IN "EVACUATED" LONDON

The maternity hospitals of London are working under more than ordinary difficulty. The position was complicated in the first instance by the proposed evacuation of expectant mothers, then by the refusal of many of the women to be evacuated, and finally by the return to London of a number of women who had gone to the reception areas. Such returns have taken place so frequently that the new word "de-evacuation" has had to be coined. In some cases, we were told, it is the husbands who have insisted on the wives' return owing to dissatisfaction with country midwifery and other arrangements, but this must not be taken as a reflection on the services in reception areas generally.

Queen Charlotte's

On inquiry at Queen Charlotte's Maternity Hospital, the largest in the country, we were informed that it was carrying on as usual in the old buildings in Marylebone Road, except that it has only sixty beds in place of the usual eighty. At the new Queen Charlotte's at Hammersmith the laboratories have been temporarily closed, the Medical Research Council having withdrawn the leading workers for duty elsewhere, and the isolation building has been taken over by the borough council for other purposes. The new buildings, one of them approaching completion, cannot be used at the present time. Two special difficulties were mentioned at Queen Charlotte's, and no doubt they apply elsewhere. One of them is financial, due to the reduced earnings of the husbands of patients. The other arises from the fact that practically all the honorary staff had volunteered for national service, and on the outbreak of war took up duty in the outer hospitals of the sectors. With regard to teaching, it is the earnest desire of Queen Charlotte's that medical students and pupil-midwives should present themselves at the school as and when the teaching staff return. Such classes at the hospital as are now held are full to overflowing, some other hospitals in London having suspended their teaching facilities. The clinics are being maintained, and the domiciliary service is as nearly as possible on normal lines. The motor-cycles used by the forty midwives, on which they carry all their equipment, do eighty miles to the gallon, so that petrol restriction is not likely to affect this branch of the hospital service. The district covered by Queen Charlotte's is a very wide one, extending over the west of London and "half way up the Great West Road." One unhappy result of the closing down at Hammersmith is that the human milk bureau has had to go out of action temporarily. This was a service of national importance, and the hospital is now hard put to it to supply human milk for desperately ill babies.

Other Institutions

Another of the great maternity institutions, the City of London Maternity Hospital, which ordinarily has eighty-one beds available, is carrying on with sixty-seven in the City Road, but it is also supplying a maternity unit for a reception district in Hertfordshire, and has a branch hospital at Hatfield at present occupied by twenty-five patients. The City of London Maternity Hospital is also admitting private patients and is carrying on with its district work in the city area. Both at the City Road and in Hertfordshire pupil-midwives are being taught and post-certificate instructions given, as well as a course for nurses in analgesia. It was mentioned at the City Road that owing to the fact that the hospital is taking emergency cases which would ordinarily have gone to St. Bartholomew's or the London Hospital, as many as twelve Caesarean sections were done during the first three weeks of September.

The General Lying-in Hospital in York Road, Lambeth, which is the third of the great midwifery teaching hospitals, is closed except for office administration and for the domiciliary service, which is being carried out as usual—indeed to a greater extent than usual—in the neighbouring boroughs of Camberwell and Walworth. The closing of the hospital is due to its situation, which was considered not suitable for war-time hospital planning, but it has been entrusted with the care of lying-in and expectant London mothers in three districts in Hertfordshire—though not mothers from the particular district in London in which it is accustomed to work. These districts are St. Albans, Radlett, and Ware, where houses have been taken for the purpose, and teaching is fully carried on. At the Mothers' Hospital (Salvation Army) at Clapton, which has one hundred beds, fifty are at present occupied, and it is expected that the other fifty will be used as the Ministry of Health desires the hospital to admit gynaecological cases. The eight districts attached to this hospital are also very busy, and the teaching of pupil-midwives is proceeding as usual. The outstanding fact of the whole situation is that a larger number of women are being confined in their own homes, and the midwives on district duty will have a very busy and responsible time.

THE MEDICAL DEFENCE UNION

Another year of useful service to the medical profession was reported at the annual meeting of the Medical Defence Union which took place at 49, Bedford Square, W.C. The membership of the Union now stands at over 22,000, and the funds available at £130,850. On the question of the position of practitioners on national and military service, the annual report points out that many medical men during war will be brought into closer professional association with members of the public, and that they should therefore maintain their membership of the Union to secure continuity of protection should charges of negligence or the like be brought against them.

In their usual summary of the cases submitted to them the solicitors to the Union (Messrs. Hempsons) draw attention to two cases of special interest. In one of these a patient, badly hurt in a motor accident but not unconscious, was attended by a general practitioner and approved his calling in a surgeon. Before the treatment could be given, however, the surgeon's retainer was somewhat abruptly determined in favour of another surgeon, and liability was repudiated on the ground that in calling in the first surgeon the practitioner had acted on his own initiative and without authority. In the county court it was word against word, and the judge accepted the patient's denial and dismissed the claim. It appears that a general practitioner has no implied authority to pledge the patient's credit to the extent of consultant's fees save in very exceptional circumstances.

The Missing Swab

The other matter was a "missing swab" case, and the Union has gained a point towards establishing the view that a surgeon is not liable for the omission to remove all swabs that have been inserted during an abdominal operation provided he is satisfied that a reasonable system of checking and counting swabs is in use at the hospital or nursing home, that the nurses and others assisting are fully qualified, and he has been assured that all swabs are accounted for. In this case in which a swab had been left in a special jury gave a verdict against the surgeon, but the Union appealed to the Court of Appeal, who overruled the jury's findings and ordered a new trial, of which order, however, the plaintiffs have not taken advantage. It cannot be said, of course, that this is a verdict in favour of the surgeon; it is tantamount to "not proven," but the solicitors say that there are two very important matters inherent in the decision. In the first place it makes it clear that the case of James *v.* Dunlop (1931) is not an authority for the principle that the surgeon is *ipso facto* liable for a miscount, but that all that case decided was that on the particular facts there was negligence. Secondly, the decision means that the principle of *res ipsa loquitur* (that the facts speak for themselves) has no application to a case of this kind. It was held by the majority of the Court of Appeal that in such a matter it was the duty of the plaintiff alleging negligence to prove it, and that it would not be safe to beg the question of proof by suggesting that certain things could not happen without negligence.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY OCTOBER 14 1939

PROGNOSIS IN TOXAEMIAS OF PREGNANCY

In the not very distant past it was commonly supposed that women who survived eclampsia and its immediate risks made a quick recovery and could later undergo further pregnancy without fear of renewed danger. There is now abundant evidence to show that this view is incorrect; a considerable proportion of these women are permanently crippled in health, and there is a ten to twenty times greater liability to a recurrence of the eclampsia in subsequent pregnancy. The exact nature of the residual disease has been the subject of much discussion, but it has been generally assumed to be a chronic nephritis, occult or revealed, resulting from glomerular damage. In a recent paper read before the British Congress of Obstetrics and Gynaecology Professor F. J. Browne and Miss G. H. Dodds[1] presented results of a comprehensive study of the after-histories of 400 patients who had been under treatment for pregnancy toxaemia in University College Hospital since the inception of the obstetrical unit twelve years ago. Most of these patients had been repeatedly examined over a period of many years. This valuable paper throws much light on the question of prognosis, and while certain previous beliefs are confirmed others are clearly disproved.

The chief facts brought to light by the analysis are the findings that continued hypertension was present in a large proportion of the patients in the eclamptic and pre-eclamptic groups, and that chronic nephritis of the type characterized by albuminuria, high blood urea, or impaired kidney tests was not present in any case. This latter observation in particular is at variance with current teaching, although several recent writers have prepared us for this view. Thus, Theobald in 1933 stated that the Registrar-General's returns did not show any significant difference in the death rate from Bright's disease between married and unmarried women, or even between women and men. In considering this question it must be remembered that chronic cardiovascular change is intimately bound up with the function and pathology of the kidney, and it may therefore be fair to say that current teaching is more at fault with regard to its definition of nephritis than to its basic meaning. Be that as it may, it is safe to say that chronic glomerulo-nephritis can no longer be regarded as a sequel of toxaemia of pregnancy.

Hypertension (defined as a blood pressure in excess of 130/75) was present in 60 per cent. of eclamptic and in 50 per cent. of pre-eclamptic patients. There is therefore no support for the prevalent belief that eclampsia carries a less dangerous remote prognosis than does a continued pre-eclamptic toxaemia. To some it may seem that the standard for defining hypertension is set too high. If, however, a modified standard of 140/90 is used, 30 per cent. of patients in the eclamptic group still register an excessive blood pressure. Browne and Dodds believe that in these patients there is a familial tendency to hypertension, and that pregnancy merely hastens its onset. It would be interesting to know the incidence of hypertension in a comparable group of healthy non-parous women of similar ages drawn from a same area; possibly such an analysis will later be forthcoming. Another important observation is the fact that albuminuria may linger after pre-eclamptic toxaemia for twelve or even fourteen months before it permanently disappears. In spite of this the kidney behaviour as revealed by functional tests is apparently normal. This delayed healing has in the past been mistaken for evidence of glomerulo-nephritis; the necessity for a prolonged observation is thus emphasized.

Patients showing recurrent toxaemia in succeeding pregnancies were in most cases found to have hypertension continuing between the pregnancies. Sixty-five patients known to have hypertension before pregnancy, or at least before the twentieth week of pregnancy, and in whom no other sign or symptom of disease could be detected, were followed through a total of eighty-five pregnancies. In this group 9.2 per cent. died within the twelve months under review. In spite of this high death rate it is stated that pregnancy does not appear to have an obviously detrimental effect, and the high death rate is to be explained by the assumption that the expectation of life in this group is already very poor. True chronic nephritis of the glomerular type complicating pregnancy was found in only seventeen women. It is interesting to know that nine of these patients passed through pregnancy without any obvious aggravation of the original chronic nephritis. On the other hand, five patients in this group died in the period under review; the opinion generally held regarding the gravity of this condition is thus confirmed. A blood urea level of over 40 mg. per cent., the presence of albuminuric retinitis, or increasing albumin in the urine are danger signals which urgently call for termination of pregnancy.

This investigation illustrates the value of clinical observation patiently continued over a long period of years. It is doubtful whether such work would be possible except in a special department staffed by whole-time, or substantially whole-time, workers. At a time when university policy regarding the establishment of "clinical units" is being subjected in certain quarters to adverse critcism, this publication comes as a striking example of the valuable research which is now being fostered by the system. We look forward with interest to further contributions regarding pathological and biochemical studies which have been made concurrently with the present clinical investigation of pregnancy toxaemia.

---

SOCIAL HYGIENE IN WAR TIME

The British Social Hygiene Council, which was originally known as the National Council for Combating Venereal Diseases, came into existence twenty-five years ago as a result of what we may presently cease to call the "great war." Naturally, therefore, it has felt an increased sense of responsibility in view of emergency conditions, the increase in the armed forces, and the feeling of general insecurity, all of which bring their own psychological dangers. During the war of 1914–18 it is estimated that about 400,000 men of the British forces were treated for venereal disease, which meant their withdrawal from military service for an average of five or six weeks, while the damaging effect on the civilian population and the children was apparent during later years. The incidence of venereal diseases among the civil population is thought to be lower now than it was in 1914, though there are no figures available for the earlier year because no free treatment centres had then been established, and it would not be relevant to take the immediate post-war period, when conditions were quite abnormal. The twenty-fourth annual report of the council (published in the latter part of July) calls attention to the number of militiamen under training, the doubling of the strength of the Territorial Army, the recall of a number of Army reservists, and the expansion of personnel in the Navy and Air Force. During the present year, before the crisis had ripened into war, 700,000 young men were or had been in camp and depot, with their necessary removal for shorter or longer periods from normal conditions of employment and family life.

The council holds that it is essential that education on the place of sex in life and guidance in sex behaviour should be given to all young men while under discipline. Medical instruction on the dangers of venereal disease is provided by the military authorities, but some more positive preventive measures are considered necessary. The incidence of both syphilis and gonorrhoea in the defence forces fell steadily in recent years. In 1921 in the Army the admissions to hospital for all forms of venereal disease were 74 per 1,000 strength; in 1931 this figure had fallen to 32, and in 1936 to 27.3. In the Navy there has been a fall from 113 per 1,000 strength in 1921 to 69 in 1931 and 57 in 1936; while the Air Force showed an admission rate of 36 per 1,000 in 1921, which had fallen to 14 in 1931 and 9 in 1936. Nevertheless there are a definite number of new cases, and the question which arises is where the women and girls who were the partners of these infected men obtain treatment, if they obtain it at all. A perplexing element in the situation is the discrepancy between the number of men and of women who have sought treatment for gonorrhoea at the centres—nearly four men to one woman—which suggests, after allowing for other factors accounting for sex difference, that there are probably a large number of women in the community suffering from gonorrhoea in various stages without ever seeking treatment. In centres such as Edinburgh, where an adequate social service is attached to the treatment centre, and where close co-ordination exists between the various medical services of the municipality, the numbers of men and of women are almost equal. From a questionary issued to medical officers in charge of 186 treatment centres in England and Wales a year ago it appeared that there were only three whole-time and twelve part-time venereal diseases almoners. In one county (Staffordshire) a detailed inquiry was undertaken. In the two county borough centres the cases of recent infection for gonorrhoea numbered 267 males and 100 females, and only 125 contacts had been brought under medical care at the centres, the untraced contacts numbering 242. Neither centre had a trained almoner or social service worker. In another group of ninety-four county patients, partners or wives were traced in only twelve cases, leaving eighty-two untraced contacts. An obvious stumbling-block in the way of the almoner making inquiries as to contacts is the risk which he or she runs of an action under the law of libel, and in a conference with naval authorities at one of the major ports it was found that this was a real deterrent to such social service in connexion with the centres. It is felt that communications between medical men and their official representatives, the almoners, should be regarded as privileged, but it will need either an amendment of the law or a test case before that can be established.

The revival of D.O.R.A. has also concerned the council, which is anxious to prevent a renewal of the difficulties that developed during the last war through the introduction of powers under that Act which were at variance with both public opinion and the voluntary treatment scheme. A suggestion has been forwarded to the Government with regard to the kind of section which might be embodied in emergency regulations without arousing the controversy which followed the introduction of 40 D in the original D.O.R.A. This concerns persons who are in an infectious condition, refuse treatment, and expose others to risk; and who it is felt should be placed under suitable control with facilities for treatment on modern lines.

SALUTE TO HARVEY CUSHING

The death last Saturday of Harvey Cushing removes a great surgeon and humanist. For many years British surgery has acknowledged his fertilizing mind and pen, and there are few if any surgical clinics concerned with operations on the brain that have not been inspired by his pioneer work. In America he is rightly looked upon as one of the greatest figures that the United States has produced in medicine—the man who created a new field of surgery and established a school whose ideals and methods have influenced surgeons everywhere. Harvey Cushing had pupils and admirers throughout the civilized world: universities, colleges, and learned societies delighted to honour him. In no country was he held in higher regard and esteem than in Great Britain, where every neurological clinic recognized him as the leader of intracranial surgery. His influence and achievements are part of the history of modern medicine. It was well said of him six months ago: "Harvey Cushing has flown higher and sustained his flight more consistently than any of his medical contemporaries.". With regard to his pioneer studies of pituitary tumours we read: "He held the key to endocrinology. . . . The story of the pituitary is not yet complete, but the work of Harvey Cushing has accelerated progress in one of those inspired bursts of speed that characterize great epochs in the history of disease."

RESIGNATION OF SIR FREDERICK MENZIES

Widespread regret will be felt at the announcement that Sir Frederick Menzies has resigned his position as medical officer of health and school medical officer to the London County Council. The regret will be accentuated by the fact that the retirement has come about at his own request, a year earlier than it would have fallen due under the age limit, owing to the virtual disappearance for the duration of the war of the L.C.C. public health department and the hospital services as a unit organization. In seeing his work dispersed and his plans for the future indefinitely postponed Sir Frederick Menzies shares the distressing experience of many others who have to do with public health and hospitals at the present time. The exigencies of the war have uprooted in a day what it took many careful years to plan. But the London County Council service had been built up to an efficiency which made it a pattern to the whole country, and indeed to public health work everywhere. Sir Frederick Menzies has had a very full career in the public service. It would be tedious to recount all the departmental committees and voluntary bodies of which he has been a member; but mention should be made of his work on the departmental committee some ten or twelve years ago which was concerned with the training and employment of midwives, and on the more recent interdepartmental committee which has had to do with the nursing services. He was also one of the founders of the Central Council for Maternity and Child Welfare and of the Central Council for the Social Welfare of Girls and Women. He first entered the service of the London County Council thirty years ago as a part-time officer, while he was deputy medical officer of health for the borough of Stoke Newington. A year or two later he came on to the whole-time establishment of the L.C.C., and was immediately charged with some large constructive enterprises, having to do particularly with the provision of tuberculosis dispensaries, with facilities for the diagnosis and treatment of venereal diseases, and with all the undertakings which are comprehended in the term maternity and child welfare. In 1926 he succeeded the late Sir William Hamer as the head of the public health and school medical services of the Council. It was as a school doctor in 1909 that he first became associated with the Council's work. At that time the number of school children examined each year, the number treated, and the provision made for treatment facilities were almost negligible. To-day, or until the war interrupted this great social service, the number of examinations, routine or special, and of reinspections is not far short of half a million a year, and the number of children treated at the school treatment centres or elsewhere is well over 300,000. Under Sir Frederick Menzies's guidance the transfer to his Council of the duties imposed by the Local Government Act, 1929, took place with such smoothness, notwithstanding the complicated nature of the services to be transferred and the vast area and population to be covered, that hardly any of the transferred staff or the patients realized that in a night—actually on the last night of March, 1930—a great new hospital authority had come into existence. This work meant the taking over by the public health department of seventy-five hospitals, with a total accommodation of about 70,000 beds, provided for practically all classes of diseases, together with a staff of some 19,000, and in addition the whole of the Poor Law district medical work for the county and a vast ambulance organization. All the services in the sphere of medical administration, whether conducted under public health or Poor Law powers, were unified under the control of the county medical officer of health, and the immediate successful development and co-ordination of the transferred services in London was of immense value as an inspiration and model to the country as a whole. All who have come into contact with his vigorous personality and practical mind will hope that Sir Frederick Menzies in his retirement may find abundant opportunity for placing his knowledge and experience at the disposal of official and voluntary organizations. We can ill afford to lose one who was described by the public orator at the University of Edinburgh some years ago at the conferment of an honorary degree as "one of the foremost exponents of preventive medicine in this country."

OPIUM: BOON AND BANE

In *The Trail of Opium*[1] Miss Margaret Goldsmith has, in nineteen chapters, told the story of the use and abuse of opium from prehistoric times to the latest operations at Geneva under the League of Nations. The book is pleasantly written and illustrated with pictures of opium dens and smokers and some of the ingenious contrivances adopted by illicit traffickers. There is nothing of the official apologist for the Indo-Chinese opium trade in these pages, and most of the authorities referred to are those who have written critically of Governmental action or inaction. The unedifying story of the East India Company's opium policy is related, leading to the conclusion that it was conducted on the cynical principle enunciated by Warren Hastings. He declared: "Opium is not a necessary of life, but a pernicious article of luxury, which ought not to be permitted but for the purpose of foreign commerce only, and which the wisdom of the Government should carefully restrain from internal consumption." The so-called "Opium Wars" of 1839 and 1857, officially asserted to have had no connexion with opium, were then condemned by Mr. Gladstone as unjust and disgraceful. The part played by the Earl of Shaftesbury and Mr. Cobden in opposition to the Indo-Chinese trade and the invidious attitude of Sir John Bowring are referred to. The constitution and conclusions of the Royal Commission of 1894, which justified the export of Indian opium to China, partly on the financial ground that the revenue derived from it was indispensable for the efficient government of India, are criticized. Mr. John Morley, in 1906, when Secretary of State for India, admitted that that Commission had "failed to satisfy the consciences" of those who had studied the question. A new policy of concurrent reduction of production of opium in China and its export from India was initiated in 1908. The author summarizes the work of the Shanghai Commission of 1909, and of The Hague and Geneva conferences and conventions, and concurs in the conclusion of the League of Nations that the limitation of the production of opium is essential alike to the suppression of illicit traffic and to the restriction of it and its alkaloids to medical and legitimate purposes. The advocacy of this fundamental necessity for dealing with the raw materials from their source is familiar to readers of the *Journal*, which has urged the adoption of this policy for the last twenty years. Due credit is given by Miss Goldsmith to the successful work of Russell Pasha and the anti-narcotics bureau in Egypt. Attention is called to the large proportion of revenue in the Straits Settlements derived from opium sales and also in British North Borneo and Brunei. The concluding chapters show how the "six-year plan" announced by China to rid the country of opium, of which at present it is one of the largest producers, is frustrated by the policy pursued since the Japanese occupation. According to the American representative on the Advisory Committee at Geneva, huge quantities of Iranian opium have been consigned to the Japanese army and firms in North China and Shanghai. From these sources drug-shops and clinics, under Japanese and Korean protection, are supplied, and so the drug is peddled to the Chinese. According to Dr. Wellington Koo, "a new form of chemical warfare" is thus added to military invasion and bombardment. *The Trail of Opium*, while perhaps not entirely free from some anti-opium prepossession on the problem, is well worthy of study by students of social welfare who are alive to the perils of narcotic addiction.

HIGH BLOOD PRESSURE

The problem of hypertension still bristles with difficulties, and the more we know about the condition the less inclined are we to dogmatism about causation. That it is by no means easy to evaluate experimental and clinical evidence in this field has been clearly noted in recent reviews.[1] [2] It seems to be generally accepted that arteriosclerosis must be regarded as a secondary or coincidental change in essential hypertension, while the absence of increased cardiac output or viscosity of blood in early cases of this disorder points unmistakably to peripheral vasoconstriction of some form as the fundamental pathological disturbance. The obvious suggestion that a disorder of the blood-pressure regulating mechanisms, especially those related to the carotid sinus, might be concerned is not entirely borne out on investigation, since hypertensive patients usually show normal vasomotor reflexes from this area. These findings do not, however, entirely remove the possibility that some limitation of the efficiency of the "moderator" mechanisms may be a factor. The theory that ischaemia of the medulla may play a part is apparently negatived by the normal functioning of the respiratory centres in patients with hypertension, and it seems clear that attention must be focused on nervous and humoral factors affecting the peripheral vasomotor endings of the autonomic nerves. Pickering pins his faith on chemical factors, mainly as a result of experiments on the blood flow through the hypertensive hand, which shows no abnormal increase when nervous influences are removed by raising the temperature, and he concludes that chemical forces are at work at the periphery. It must be admitted that it is apparently easy to produce pressor bodies by experimental ischaemia of the kidney. On the other hand, humoral agents have not yet been practically demonstrated in actual cases of hypertension, and it appears that the blood pressure of normal individuals does not rise when they are transfused with large volumes of blood from patients with hypertension. Such obstacles to a clear-cut case may have encouraged other observers to look more closely at the constitutional and psychological characteristics of the patient with high blood pressure. The difficulty of obtaining patients for investigation before the clinical picture and aetiological situation are confused by late vascular disease seems to have been overcome in a number of cases of essential hypertension which have been examined by American psycho-analytic investigators. Their studies reveal that these patients showed as common characteristics external poise, gentleness, and amiability. But, according to these workers, this docile and unaggressive façade concealed a strong rebellion which was much more representative of their real nature. Further confirmation of these interesting observations is required. It is not improbable that emotional disturbance may be the connecting-link between the neurogenic and humoral factors in hypertension.

A MEDICAL MISSION IN CHINA

The League of Nations sent out a medical mission early in 1938 to assist the Chinese authorities to protect the civil population against epidemics, and an interesting account[1] of the work of the French contingent in the south of China has recently been given by M. A. Lasnet. He decided to follow the territorial organization already used by the Chinese medical service, and therefore sent to each of seven districts a medical officer with staff and a lorry, setting up his own headquarters in Canton. Co-operation with the Chinese local services, with the national anti-epidemic service, and with certain units of the Red Cross which were in the neighbourhood complicated the work of the mission but made it much more effective than it would have otherwise been. The laboratory was the central point, and without it nothing could have been done: its task was to carry out diagnostic tests and manufacture sera and vaccines. The three chief diseases which had to be dealt with were small-pox, cholera, and malaria. Small-pox is endemic over the whole of South China, especially in the Kwangsi districts. In spite of the initial difficulties, the mission performed in the course of a few weeks 1,200,000 vaccinations. Cholera is a summer epidemic, and constituted a very serious problem. A large staff was occupied in investigating, isolating, and treating the patients, disinfecting water supplies, inspecting markets, and other duties. A million and a half vaccinations were performed. The campaign against malaria had to be restricted to the distribution of quinine, as only a long-term engineering policy would free those marshy plains from the parasite. The mission took out over 1,500,000 tablets, but really needed four or five tons. It also had to set up, against the tradition of centuries, a sanitary organization in Kwangsi: to build latrines, sewage tanks, and incinerators; to protect wells; to carry out education and propaganda by many different means; and to instruct the authorities in running health services. It had to do all this under intermittent bombardment by Japanese aircraft, and afterwards under threat of invasion of the country. At the time of M. Lasnet's report the mission was still active.

ARTIFICIAL LIMBS AND AMPUTATIONS

The fine work undertaken by the Ministry of Pensions in providing artificial legs and arms to the 42,000 officers and men who suffered limb amputation through service in the war of 1914–18 is well known to the medical profession. The unprecedented demand for limbs stimulated the production of improved technical devices and higher standards of material and workmanship, while the ingenuity of the technician has been guided into the desired direction by the Ministry's surgeons responsible for choosing the most suitable limb for the particular case and supervising its fitting to the stump in accordance with the surgical requirements. Limb-fitting has thus become a newly and highly developed technique in surgical practice, and the Ministry can lay claim to have become a pioneer in the development of the modern surgery of amputations and in the design and construction of all types of artificial limbs and appliances. Beyond providing limbs for pensioners it meets the requirements of the Service Departments, and recently, by arrangement with Queen Mary's (Roehampton) Hospital Committee, the facilities at that hospital and the Ministry's limb-fitting centres in the provinces have been made available for civilian patients throughout the country. Lectures and demonstrations have also been given at Roehampton to surgeons nominated by public and local authorities and civil hospitals. An account of the special knowledge and experience gained in the organization of this service for the provision of artificial limbs is given in a handbook prepared by medical officers of the Ministry of Pensions entitled *Artificial Limbs and their Relation to Amputations*, which has just been issued by H.M. Stationery Office (price 3s.; post free 3s. 4d.). Its preparation was initiated by Dr. J. H. Hebb, the Director-General of Medical Services, before his present service with the Ministry of Health. The book deals with every important aspect of the subject, including the leading features of present-day principles and practice in the surgical fitting of limbs and details of specifications of various types of artificial limbs.

The Emergency Committee of the London County Council has received with regret the resignation, on health grounds, of the county medical officer of health, Sir Frederick Menzies, K.B.E., K.H.P. It is recommending the Council, at its meeting on Tuesday next, to accept the resignation with effect from November 2, and to place on record the Council's high appreciation of his services as medical officer of health for the past twenty-eight years. The Emergency Committee is also recommending the Council to appoint Dr. W. Allen Daley, the deputy medical officer of health, to succeed Sir Frederick Menzies as medical officer of health.

The Medical Research Council, at the invitation of the Ministry of Health, has formed a Therapeutic Requirements Subcommittee, which will advise the Ministry and the medical and pharmaceutical professions on matters relating to economy in the use of drugs and therapeutic substances. All communications regarding the work of the subcommittee should be addressed to Dr. C. H. Hampshire, 44, Hallam Street, London, W.1.

Lord Horder has, at the invitation of the Minister of Pensions, accepted appointment as honorary consulting physician to the Ministry.

WAR WOUNDS AND AIR RAID CASUALTIES

The following article is a supplement to the series of lectures on war wounds and air raid casualties printed in these columns*

CHEMICAL WARFARE AND THE DOCTOR—II

BY

E. M. COWELL, C.B.E., D.S.O., T.D., F.R.C.S.
A.D.M.S., 44th (H.C.) Division T.A.

Technique of Attack by "Gas"

Service medical officers should study *Gas*, by Major-General C. H. Foulkes (1936), where a full account is given of the various methods of employing chemical warfare in the field. These include the use of drift-gas from cylinders, mists and mixtures from projecters fixed electrically, Liven's drums, Stokes's motor bombs, "M" generators (thermo-generators on the smoke-candle principle, for generating clouds of the arsenic mists), sprays from aeroplanes, as well as various types of gas shell fired by the artillery.

Gas attacks on the civil population will be made from the air. Mitchener and Cowell, in their *Medical Organization in Air Raids*, 1939, quote General Golovine, who gives statistics showing that the complete over-whelming of a capital city by gas is impossible. Repeated attacks may be made by small formations of three to nine machines, or larger numbers—twenty-seven to thirty-six. As the air defence of this country becomes stronger this menace is proportionately diminishing. It is possible for gas to be sprayed by a low-flying machine or clouds to be laid at a height. The spray from the former may be seen coming from the machine and falls like rain; from the latter the mist may arrive from some distance, its presence being only appreciated from its effects.

For the success of a gas attack weather conditions must be favourable. Clear, mild, still nights, with an absence of mist or rain, afford the best chances for success, both for non-persistent and persistent gases. Heavy rain and a high wind will minimize the toxic effects. Clear sunny days cause rapid dissipation of the non-persistent gases; a raised ground temperature increases the volatilization of the persistent gases and gives rise to a high local concentration.

Counteraction of Gas Attacks

The object of any gas raids undertaken against the civil population will be to inspire panic, confusion, and terror, with such a lowering of national morale that peace will be insisted on at any price. The air menace may be averted in four ways: (1) Reliance on agreements, pacts, and action by such bodies as the League of Nations; (2) active defence, by the provision of a powerful Air Force; (3) passive defence—anti-aircraft units, batteries, searchlights, etc.; (4) air raid precautions. No. 1 needs no comment. The second and third are becoming stronger every day in this country. With regard to air raid precautions the Government's plans are gradually being perfected. But further organization and liaison between various departments, provision and training of more personnel, and repeated exercises and practice are required to render this arm of defence as efficient as the second and third.

The doctor not a member of the medical branch of the fighting forces will help in A.R.P. work. It has already been realized by the Home Office, Ministry of Health, and the British Medical Association what an important part the medical practitioner can play, whether surgeon, physician, or family doctor. He can help not only in preserving the calmness of the public, and preventing the effects of chemical warfare by correct prophylaxis, but also, by his knowledge of both first aid and treatment of gas, save life and hasten recovery.

It is essential that the whole nation be made gas-conscious. This applies not only to members of the A.R.P. services, including all medical personnel, but also to all members of the public. Refugee and evacuation camps may be attacked by gas as well as the densely packed centres of the cities. Further instruction is needed, and a stricter gas discipline, with frequent respirator practice, is urged. Details of protection by sealed rooms, protective clothing of different types, and the wearing of one of the three types of respirator are to be found in the Home Office Manuals. Dressing stations, first-aid posts, and operating theatres in vulnerable areas should not only be splinter-proofed but gas-proofed.

All doctors are advised to practise wearing an anti-gas respirator. Familiarity with the general service type will ensure the comfortable wearing of the civilian duty and civilian anti-gas types. Details may be obtained from the books, but actual frequent practice is essential. The doctor should be able to get his respirator on in ten seconds or less and wear it for at least one hour, even with spectacles on, without the eyepieces dimming or any loss of technical efficiency. One can lecture for forty minutes on the respirator alone without repeating oneself.

It is quite feasible to perform surgical operations wearing a general service respirator, even when the surgeon has to wear glasses. Wearing the haversack at the back instead of the front of the chest ensures a sufficient supply of air when wearing sterile clothing. Theatre sisters should be taught to wear either a civilian duty respirator or, better, the G.S. pattern slung at the back, in which position it will not get in the way when stooping over instruments.

Prompt diagnosis is the first essential. It must be at once ascertained whether the "casualty" has really been exposed to gas, and, secondly, if so, the nature of the gas must be determined. A record of each case should be made and preserved on the special form prepared by the Ministry of Health. Information on the following points can generally be given by the patient or a friend: (1) condition of exposure—that is, air, spray, exposure to contaminated clothing, etc.; (2) nature of the smell; (3) duration of exposure; (4) immediate effects; (5) late symptoms; (6) when did the exposure occur?

War Gases and their Effects: Group I—Lacrimators

The liquid lacrimators may be sprayed or dropped by bombs from the air. C.A.P. requires heat. The presence of one of these substances causes an immediate irritation of the sensory-nerve endings of the conjunctiva and cornea. Profuse watering of the eyes and spasm of the

---

* Received for publication on August 4.

lids temporarily blind the victim. Further concentrations may cause mild respiratory discomfort. No permanent lesions are produced, and when removed from the contaminated atmosphere all symptoms disappear in one to two hours. C.A.P. may irritate and redden the skin. An account of one case was personally communicated to me by Dr. A. C. Coleman. A young lady stayed twenty minutes in a C.A.P. chamber. A few hours later she developed severe urticaria, which fortunately immediately responded to injections of adrenaline. Perfect protection is afforded by the respirator.

First Aid.—Diagnose on the immediate lacrimation and blepharospasm. Apply respirator and remove to clear atmosphere. Irrigate the eyes with warm saline (very seldom necessary). Reassure the patient; he will recover within twelve hours. Do not send him to hospital. Established cases do not require any special treatment.

Group II—Sternutators

These are the arsenic compounds, and require heat or detonation to form them into a fine mist of minute particles. This gas cloud may be almost invisible. There is a latent period and some minutes elapse before symptoms appear. Thus symptoms may arise or become worse after putting on a respirator; an untrained person tends to take off his respirator, thinking he is no longer being protected. This is in direct contrast to Group I, where symptoms are immediately relieved by putting on the respirator. The symptoms are those of severe pain in the nose and sinuses, with repeated sneezing, burning of the throat, sore eyes, aching gums, and possibly nausea or vomiting. Mental distress may be a prominent feature, and inability to think or concentrate is generally experienced. Although alarming, the symptoms generally disappear in an hour. No permanent damage is done, and these cases need not be admitted to hospital. Modern respirators contain cellulose pads to filter off the arsenic smokes.

First Aid.—Diagnose on symptoms and the history, and do not be deceived by the severity of the symptoms and the anxiety of the patient. Apply respirator; remove to clear atmosphere. Reassure the patient; recovery will occur in an hour or two. Do not send to hospital. If the pain in the sinuses is very severe, light chloroform inhalation will give relief. For a painful nose or throat 5 per cent. sodium bicarbonate solution may be used as a wash or gargle.

Group III: Vesicants

MUSTARD

Mustard is a very insidious poison. It may escape immediate detection and does not produce symptoms for some hours. Repeated exposure may lead to hypersensitivity. Lesions may result from spray from the air, splashes from bursting bombs, or slow vaporization from contaminated buildings, ground, clothing, etc. On the skin no immediate sensory effect is appreciated. The poison penetrates clothing and enters the skin deeply and quickly, producing an erythema only after some hours. Local oedema and capillary stasis follow; later the erythema deepens in colour, a pale centre appears, and a vesicle containing yellow serum is formed. This does not contain mustard. Intense itching is usually noted, and the moist parts of the body are chiefly affected. Secondary infection is liable to occur and healing is slow. The healed scars may be pigmented for a time.

Exposure to vapour only may produce extensive effects on the eyes, temporarily blinding the subject within a few hours after exposure. Contamination by droplets of splash or spray is more serious, and may lead to permanent blindness from corneal scarring. Symptoms may begin within half an hour, and soon the eyelids become painful and swollen. Intense oedema of the lids follows, together with swelling and reddening of the conjunctiva. Corneal opacities appear, the ocular conjunctiva may ulcerate, the tension is increased, and a profuse muco-purulent discharge takes place. Photophobia and spasm of the lids may be intense.

If the respirator is not put on soon enough then the nose, larynx, trachea, or lungs may be affected. Epigastric pain and vomiting may occur from the swallowed saliva. The effects, however, do not persist. Renal complications have been noted in fatal cases. Local oedema of the penis may cause retention of urine.

Mustard Vapour.—If in from twelve to twenty-four hours after exposure to a dilute mustard vapour the eyes become red, the voice is husky, and the skin erythematous a positive diagnosis may be made. Prevention consists in wearing protective clothing, applying the respirator, and washing in soap and water or rubbing in bleach ointment for one minute. First aid consists in changing all clothing, complete bathing of the body, and repeated eye lavage. This suffices for mild cases. Note that speed is essential: cleansing must be undertaken within two minutes for liquid and fifteen minutes for vapour, otherwise burns will result. The same applies to Lewisite, except that the poison is appreciated at once and the characteristic smell is always found.

Liquid Mustard.—Yellow detector disks reveal splashes of mustard as bright red spots (red for danger). If clothing is found contaminated it must be removed as soon as possible and the patient treated as mentioned above. If the eyes are contaminated warm saline irrigation must be carried out immediately and be maintained at hourly intervals. In the open, water from a water-bottle should be poured into the eyes, followed by a drop of liquid paraffin.

LEWISITE

Lewisite resembles mustard in its action, but is less insidious. It is early detected by its odour and has a shorter latent period, both in the eye and on the skin. In extensive burns acute arsenical poisoning may result. On the skin an immediate stinging sensation follows the application of liquid lewisite. Erythema occurs within thirty minutes; vesication, too, is early, and is complete within twelve hours. Clinically the effects of lewisite and mustard can now be sharply distinguished. The lewisite blister is clearly defined: it covers the whole erythematous area and is filled with a cloudy fluid containing leucocytes and arsenic. The mustard blister has a surround of erythema and is full of a clear yellow fluid, but contains no mustard. On dry clothing lewisite is less effective than mustard, and when the clothing is wet the lewisite loses much of its effectiveness owing to rapid hydrolysis. The fine spray of lewisite is even more dangerous to the eyes than that of mustard. Immediate irritant symptoms follow. In fifteen minutes an acute conjunctivitis occurs, oedema of the eyelids, pain, and photophobia rapidly supervene, and in three to nine hours the whole painful picture is produced, an effect which is only seen with mustard at the end of twenty-four hours. The ultimate prognosis is graver also.

Since the presence of lewisite is readily appreciated the respirator is usually put on early and affords protection. As in the arsenic smokes, the symptoms of irritation may appear even after the application of the respirator. In the absence of a respirator nasopharyngitis follows, and bronchitis may be established in twenty-four hours, which may lead to bronchopneumonia and death.

TREATMENT OF VESICANTS

Skin.—So long as droplets of mustard are visible on the skin bleach ointment will lessen the severity of the burn. This is made by mixing equal weights of "super-tropical" bleaching powder and white petroleum jelly. It is stable in ordinary climates. If the contamination is extensive, bleach paste is easier to apply. Bleach paste consists of one part (by volume) of "supertropical" bleaching powder mixed with two parts of water. The affected area is swabbed for several minutes until no further odour remains. Any of the following solvents may be used: petrol, methylated spirit, paraffin, etc. Care must be taken to avoid fire; the contaminated swabs, after careful handling, must be burned. Cleansing with soap and water removes the surface "gas" and will prevent burns if carried out within five minutes. The dresser should wear gloves. This method should not be attempted if erythema has begun, but swabbing should be employed. If there is a massive contamination, the application of bleach ointment is advisable. In the case of established lesions, erythema, if mild, will clear up as in sunburn, leaving a slight pigmentation and desquamation. Tannic acid jelly or solution should be useful. With vesications the aim will be to prevent secondary infection. Mustard burns should be treated on the surgical principles outlined by Mitchiner and others. Thorough cleansing—under an anaesthetic if necessary—is followed by the application of a tannic acid compress—layers of lint or gauze soaked in a 2½ per cent. solution of tannic acid, freshly made; this is left *in situ* for several weeks if desired.

Eyes.—As soon as the patient comes under medical care, and while he is being cleansed in the shower-baths, an opportunity is taken to irrigate the eyes with 2 per cent. sodium bicarbonate solution. If the eye is contaminated with liquid mustard do not wait for the onset of signs or symptoms, but continue the alkaline lavage as often and as long as possible. This treatment becomes difficult as the oedema and spasm of the lids increases. To relieve this apply 1 per cent. sterile atropine ointment twice a day (and in all cases where the cornea is damaged). Do *not* apply cocaine. Do *not* bandage the eyes—apply a light shade and instil liquid paraffin at frequent intervals. If the discharge becomes muco-purulent 2 per cent. argyrol twice a day is indicated. The treatment of corneal ulcers, with or without hypopyon, is best left to an ophthalmic expert. With vapour contamination only the prognosis is better and the patient may be immediately reassured. In mild cases irrigate every two hours with 2 per cent. sodium bicarbonate solution, instil liquid paraffin, and apply a shade or keep in a darkened room. In more severe cases treat as for liquid contamination.

The Respiratory Tract.—Rhinitis will respond to warm douches of 5 per cent. sodium bicarbonate solution. When there is laryngitis, rest the voice, keep in the fresh air, and give a paraffin spray or vapour inhalation. (Menthol, 10 grains, tinct. benzoin. 1 oz.; sig., 1 drachm to a pint of boiling water.) Some 2 per cent. of the mustard cases in the great war ended fatally. The majority of these deaths were from bronchopneumonia. To prevent this complication keep cases where the lungs are involved in special wards, warm and well ventilated. Isolate any case of secondary infection as it occurs. Menthol is useful in allaying coughing.

As pointed out in the *Medical Manual* already referred to, it is wise to send patients as soon as possible to a special convalescent centre. This will prevent the onset of "anxiety" neurosis and such conditions as functional photophobia and aphonia. Finally, doctors looking after civilian gas casualties should remember that gassing does not in itself cause a permanent state of ill-health. Undoubtedly many gassed patients will develop neurasthenia and apply for disability pensions. Properly handled, this state of affairs will not eventuate.

PROTECTIVE MEASURES

(1) There is the standard suit fully described in the Home Office manuals. None of the recent official publications, however, mentions the important work of Major Crowden of the London School of Tropical Medicine and Hygiene. Writing in the *R.A.M.C. Journal*, this officer describes a method whereby a man can continue to perform hard manual work in full protective clothing for several hours without ill effects. A light drill shirt is put on over the waterproof and kept constantly wet with cold water. The loss of heat by evaporation keeps the wearer cool. (2) Several other types of clothing exist for troops in the field. (3) For first-aid services there are the following: (*a*) rescue and first-aid parties—a heavy standard suit; (*b*) ambulance drivers—long coat, gloves, gum-boots, curtain, and respirator or eye shield; (*c*) undressers—protective apron with sleeves, gum-boots, and respirator (generally civilian duty). The methods of decontaminating clothing and buildings, etc., are fully described in the various Home Office manuals.

Group IV—Lung Irritants

These gases may be discharged from air bombs or cylinders carried on low-flying aircraft. The gas is heavier than air and is carried down wind. Immediate application of the respirator gives complete protection, but speed is essential. A single breath of phosgene may be very dangerous.

Pathological Action.—All lung irritants act on the bronchial tubes and alveoli, causing acute pulmonary oedema. A lacrimatory effect is also produced. Chloropicrin is four times and phosgene ten times more toxic than chlorine. On post-mortem examination the chief changes are pulmonary oedema with disintegration of the alveoli. The blood becomes concentrated and tends to form thrombi. Pulmonary oedema may occur within two hours of the gassing. In the first twenty-four hours the lungs are found to be full of blood and are oedematous, with patches of emphysema alternating with collapsed areas. A pleural effusion may be present. After the second day the oedema begins to disappear, but a secondary infection leads to pneumonic patches and pleurisy. The haemoglobin may rise to 140 per cent. in the blood, and is associated with pulmonary or systemic thrombosis.

Clinical Types.—Two groups may be distinguished: the acute type with violent onset, and the acute type with insidious onset. When the onset is violent phosgene in heavy concentration and chlorine and chloropicrin will cause immediate symptoms. The patient coughs, catches his breath, and complains of a pain in his chest. The breathing becomes rapid and shallow; deep breathing brings on a painful cough. Retching and vomiting occur and the patient is knocked out. With the onset of oedema the breathing becomes rapid and shallow and the patient becomes blue, with distended veins. (See *An Atlas of Gas Poisoning*, H.M. Stationery Office, 1939.) In phosgene poisoning this blue phase may be passed over and quick collapse follow, with a rapid pulse and symptoms of toxic shock. Here the patient may die in two to three hours after exposure. This group of acute cases may be classified into (1) mild cases—flushed face, increased respiration rate, and cough; (2) severe cases—"blue" type, with a full pulse; (3) severe cases—"grey" type, with toxic shock. Type (1) soon recover; Type (2) do well if the pulse does not rise above 100; Type (3) do badly, and death results from circulatory failure or bronchopneumonia. In the group in which onset is delayed persons exposed to phosgene go on with their duties for a few hours and then suddenly collapse with a rapidly increasing pulmonary oedema, often fatal. Sir William Horrocks described to me how this delayed action was discovered in 1915. Some young pigs were exposed to a low concentration of phosgene and appeared none the worse. Next morning, however, they were all dead.

In the early stages very few physical signs are to be found. Later the percussion note may not be impaired, but the breath sounds become feeble, especially over the back, where fine rales appear. Blue cases, which respond to oxygen, may do well, and the pulmonary oedema is also over within four or five days. Grey cases with heart failure do badly. Bronchopneumonia often supervenes. In the great war 80 per cent. of lung-irritant deaths occurred within the first twenty-four hours.

Diagnosis.—There is a distinctive smell, and the history will help. Chlorine and chloropicrin produce urgent symptoms even in low concentrations. Relief is immediate on applying the respirator. Phosgene and diphosgene, however, even though smelt, can be breathed without coughing in low but lethal concentrations. Suspect casualties should be carefully questioned and examined. If it is certain the patient has been exposed to a lung irritant he should be kept at rest for twenty-four hours and watched. If the exposure has been short and there are no symptoms, he may be discharged after a further twenty-four hours.

First aid must be begun as soon as a positive diagnosis is made. The patient must be treated as a stretcher case, be kept warm and as quiet as possible, and be put on a light diet. Make preparations for giving oxygen and performing venesection if signs of lung injury supervene (dyspnoea, tachycardia, cyanosis, frothy expectoration, and concentration of the blood).

Treatment of Established Cases.—Suspect cases must be kept at rest and observed for twenty-four hours. If no symptoms have arisen in the next twenty-four hours they may be discharged. In the acute stages the treatment consists in rest, warmth, venesection, and oxygen. If the patient is tided over the first few days the oedema will absorb and recovery is possible. Treat all lung casualties as stretcher cases and after admission to hospital keep them quiet in bed. All contaminated clothing must be removed as soon as possible. As in the treatment of wound shock, it is most important to keep the patient warm. Venesection is carried out on the appearance of cyanosis: 15 to 20 oz. (400-600 c.cm.) are withdrawn by acupuncture. It is possible that further experience may show that subsequent introduction of normal saline intravenously may be beneficial. If the cyanosis deepens and pulmonary oedema increases, oxygen is initiated. Venesection is harmful to the grey cases. Oxygen may be required to be given continuously for some days. Nurses should be instructed in the use of an oxygen tent, closed or open pattern, nasal catheter, or Haldane's mask. An average of five litres a minute will be required for each patient. In the great war it was found that no patient in whom a pink colour was obtained by the use of oxygen died from pulmonary oedema.

Expectoration may be encouraged by posture. The Tor table (Mitchiner and Cowell) provides a simple method of lowering the patient's head to allow the serous fluid to escape from the lungs. No drugs were found to be of value in the great war. If pneumonia supervenes, some of the new drugs may be tried; but no opportunity has yet arisen to test their efficiency under these conditions. In treatment of the convalescent the remarks made with regard to mustard will apply here also.

Group V—Paralysants

The diagnosis of this group presents no difficulties. *First Aid*: For both HCN and H_2S prolonged artificial respiration with administration of O_2 and CO_2 is indicated. In these cases some form of artificial respiration by apparatus, such as an "iron lung," Eve-Riley rocking stretcher, or the Tor tilter, may save life. Full details are to be found in the *Medical Manual of Chemical Warfare.*

Surgical Treatment of Gas Casualties

It will probably be found that the number of wounded and gassed cases will vary inversely—that is, there will be wounded only and no gas, or vice versa. In individual cases decisions must be made according to the circumstances. A man contaminated with mustard must be stripped and cleansed and reclothed before being admitted to the pre-operation ward and theatre. General anaesthesia may be inadvisable in the case of lung-irritant poisoning, but gas-and-oxygen preceded by menthol inhalation will probably be safe in mild cases. Operating theatres, as already noted, should be splinter-proof and gas-proof. If these precautions have not been taken the surgeon and all the members of his team should be prepared to work in respirators if necessary.

Concluding Remarks

Undoubtedly many gas casualties will arise among women and children. The children will require extra nurses, and will probably fare worse than adults. I saw infants with mustard burns in some of the villages near the line in France during the last war, but only in small numbers. They made constant demands on their mothers.

When gunpowder was introduced the men of the time said, "How terrible; cannot we go back to the humane bow and arrow?" The same has been said of chemical warfare. But with careful education, preparation, organization, discipline, and determination it will be easier to protect the people of this country against gas than against high-explosive or incendiary bombs.

A short bibliography is given below: for a very full list of authors (826) the reader is referred to Hanslian, Vol. i, *Der Chemische Krieg,* 1937.

I wish to acknowledge my indebtedness especially to the most excellent *Medical Manual of Chemical Warfare,* 1939, which should be read by all doctors.

DISPERSAL OF RADIUM IN WAR TIME

We have received from the chairman of the Emergency Measures Committee of the National Radium Commission the following preliminary memorandum on dangers of the dispersal of radium in war time, written by A. R. Greatbatch, B.Sc., of the Research Department, Woolwich.

Dangers from Aerial Bombardment

In considering special dangers from aerial bombardment particular attention must be given to the disruptive action of a high explosive bomb upon radium containers and the probable dispersion of radium dust over a wide area. The effect of such disruptive action cannot be stated in precise terms or with exact detail, as the extent of the damage will depend upon a number of factors, including the type and size of bomb, the general protection afforded by the building housing the radium, the material and design of the container, and its actual position with regard to the bomb when the explosion occurs, etc.

It is therefore necessary to examine the effect of a bomb explosion in rather general terms and apply them to the particular case of radium. For this purpose it is usual to differentiate between the blast effect and that due to the fragmentation.

Blast Effect

Blast effect is caused by the extraordinarily high speed of the explosion and the succeeding pressure wave. In the case of a 500-lb. bomb—a size which may be expected to be used by enemy aircraft—any object within a range of from 20 to 25 ft. would be subjected to extremely high stresses. Large objects, unless exceedingly strong, would be shattered and smaller objects if suitably placed may, in addition, be hurled away with a velocity approaching that of the velocity of a bullet leaving the muzzle of a rifle. Glass containers within this range would undoubtedly be completely dispersed, and unprotected metal radium needles would almost certainly be disrupted and the contents scattered. Any body or envelope surrounding a needle would afford it some protection, and it is even conceivable that a needle buried in a human torso would escape destruction under some circumstances. Generally speaking, the stronger the envelope the greater the protection, and it is considered that a reasonably large measure of protection would be given by a suitably designed steel container which, unless made of special bullet-resisting steel, would require to have walls of 3 in. thickness or more entirely surrounding the radium.

Effect of Fragmentation

The danger from fragmentation is of a different nature. Here there is a possibility that a radium container may be struck by one of the many thousand bomb fragments which are hurled by the force of the explosion at velocities reaching double or even treble that of the muzzle velocity of a bullet. The danger range may extend to over 100 ft. from the bomb, and a direct hit by a fragment within this area would shatter a container unless heavily protected in the manner already described.

The protective value of the building which houses the radium should not be overlooked nor overrated, and it should be related to the fact that modern armour-piercing bombs dropped from a height of 10,000 ft. or more are capable of penetrating through about 5 ft. of concrete or about 30 ft. of earth. Thus to attain complete protection from both blast and fragmentation from a 500-lb. H.E. armour-piercing bomb it is necessary that the radium should be covered by well over 30 ft. of earth. The recommendation of the conference that radium should be sunk to a depth of 50 ft. in the ground will therefore ensure safety from danger of radium dispersal in all circumstances, including a direct hit. Similar safety might be attained by heavy concrete buildings of the requisite thickness, but the cost would be very high.

HOARDING OF OXYGEN AND NITROUS OXIDE CYLINDERS

The Ministry of Health in a notice issued on October 7 reminds hospitals, private individuals, and industrial concerns that it is contrary to the national interest for them to hoard oxygen and nitrous oxide cylinders, whether filled or empty. While there has been a definite response to the appeal made at the beginning of September the Ministry is informed that there appears to be a renewed tendency to hold undue supplies. The adequacy of the existing supplies can only be ensured if cylinders are not held in excess of actual requirements and if they are kept in constant circulation. Empty cylinders should be returned with the minimum of delay to the suppliers by whom they were issued.

Correspondence

Radium Precautions

Sir,—Dr. Cochrane Shanks is being wise after the event. There have been no air raids, therefore all precautionary measures have been scare measures. In April a letter appeared in your columns (also in the *Lancet* and *Nature*) outlining a scheme whereby radium could be got into safe keeping as an emergency measure. Not a single dissentient voice to this scheme was publicly raised. It was put into operation, and on the eve of the declaration of war it is probably true to say that over 95 per cent. of the country's radium was safely at a depth in boreholes.

Within four days of the declaration of war we were parties to discussion as to how this radium could be got out of the boreholes and put to the service of cancer and other patients under reasonable conditions of safety. These discussions have led to the formulation of a practical scheme which has for the last week been under consideration by the Ministry of Health. Dr. Shanks strikes a false note when he holds those who have been concerned with these measures of emergency, and then with schemes of war-time treatment, as responsible for the death of cancer patients, so far denied radium treatment since September 3.

If Dr. Shanks has any real doubts about the danger of dissemination of radium under the action of high explosives, we would recommend him to read the article by Mr. Greatbatch, entitled "Dangers of the Dispersal of Radium in War Time" which you have for publication in the current issue. [See left-hand column.]

Dr. Shanks's vision of the radium service of a hospital as being carried on with the commodity all tucked away in the basement safes is rather at variance with the everyday experience of it being where it is wanted—namely, in the wards, clinics, and operating theatres.

This letter may serve a purpose if only to remind your readers that the actions taken in the first instance were persistently stated to be emergency measures, and that since the outbreak of war efforts have been, and are being, made to get radium back into use under reasonable conditions of safety.—We are, etc.,

Sidney Russ,
London, W.1, October 9. George F. Stebbing.

Organization of the Emergency Medical Services

Sir,—Professor A. W. Sheen (*Journal*, October 7, p. 741) has raised a question of great importance which should receive immediate consideration. During the last war the Military Orthopaedic Hospitals (afterwards called Special Military Surgical Hospitals) were organized under the direction of Sir Robert Jones. The principles upon which their organization was based were:

That the surgical staff consisted of orthopaedic surgeons or at least of surgeons who possessed a special aptitude for and interest in the mechanical side of their work.

That the hospitals should be fully-equipped and staffed not only for the surgical and mechanical side of their work, but also for all forms of physical treatment and for rehabilitation by physical exercise, games, and occupational therapy.

That the treatment from as early a stage as possible right down to the completion of functional recovery should be carried through in one institution and under one directing head.

There can be no doubt that these hospitals had a great success. Unfortunately the principles upon which they worked were not adopted by civilian hospitals during the post-war period. But they were brought back into prominence by the British Medical Association's report upon the treatment of fractures, and the complete fracture department recommended in the reports of the Interdepartmental Committee on the Rehabilitation of Persons injured by Accident is practically an orthopaedic unit in this sense. If such units were necessary for civilian injuries, surely they are more so in war. Should we not get on with their organization and arrange for the transfer of suitable cases to them at as early a stage of treatment as possible?—I am, etc.,

London, W.1, Oct. 9. R. C. ELMSLIE.

Planned Psychotherapy in War Time

SIR,—Many comparisons have been drawn between the preparedness of the nation now and in 1914. Your correspondence columns bear striking testimony to one great difference: whereas in 1914 the majority of the medical profession were sceptical as to the value of psychotherapy, to-day we are discussing the best means of utilizing it for the rehabilitation of the inevitable psychological casualties. Dr. Geoffrey Evans bids us look in the first place to ourselves; and it is true that no doctor can remain a "neutral observer," so closely is the sufferer observing him. In the next place comes Dr. Telfer's plea for the establishment of local treatment centres, a practical step which some of us were hoping to see included as additional benefits under National Health Insurance before the outbreak of war altered the face of things. But we shall have to put our own house in order, remembering, as Rudyard Kipling said of the construction of tribal lays, that every single school of psychotherapy may be right in the sense that in skilled hands each of several methods may be successful. Do not let us therefore emphasize our differences too vigorously, lest Authority, puzzled by them, makes them the excuse for doing nothing at all. I have reason to believe that this is a real danger, and we are all agreed it would be a real disaster.—I am, etc.,

London, W.1, Oct. 10. W. LANGDON-BROWN.

Industrial Dermatitis

SIR,—The letters which have been appearing in the *Journal* since August on the above subject raise many points of practical importance. When, as in cases of workmen's compensation, medicine and the law meet for the common purpose of doing justice they necessarily approach the same point from different angles. The law must concern itself with words and the possible interpretation of them. Its definitions must be clear and precise. In medicine, whether general or special, such well-defined lines can rarely be drawn. It is therefore very desirable, as Dr. Ingram points out (September 9, p. 584), to quote the wording of the Act correctly when making any criticisms of it. "Dermatitis produced by dust or liquids" are the words that the law gives us in the way of guidance.

There is happily no definition of "dermatitis" or of "dust" or of "liquids." Indeed, the very vagueness of the wording is its strength. Occupations are so varied and the physical and chemical factors concerned are so many and so rapidly increasing in number that any attempt at a closer definition would weaken rather than strengthen the purpose of the Act. If any change is to be made in the future wording it might well be to replace the term "dermatitis" by the still more vague words "disorder of the skin" or "skin eruption." When the Act was drawn up the term "dermatitis" had no defined place in the category of diseases of the skin; to-day it has been applied, with more or less accuracy, to certain particular groups to which many skin eruptions properly recognized as of occupational origin certainly do not belong.

There is one point in Dr. Ingram's letter which I venture to think is perhaps a little too dogmatic. He says: "If a substance is suspected of causing dermatitis in an individual, then the application of that substance to the skin—in the form of a 'patch test'—will prove whether or not it is capable of producing dermatitis in that particular individual." Whilst a positive reaction may be decisive, a negative result hardly warrants the opposite conclusion. All parts of the skin are not exactly the same in their reactions to an irritant, and unless the dust is applied to the same part of the body, for the same period of time and under the same conditions as it was when at work, the comparison of its effects hardly seems justified.

Some of your correspondents suggest that if a person, known to have suffered off and on from what we used to call eczema, gets an attack while employed it is wrong that he should receive compensation for "dermatitis produced by dust or liquids." This will depend on circumstances. Such a person may be one whose skin is hypersensitive and readily flares up into a typical generalized eruption by undue exposure to dust or liquids which would have no such effect on a normal skin. In such a one this particular attack of dermatitis may rightly be said to have been produced by dust or liquid to which he has been exposed in his work.

There is one point which I think has not been alluded to in this correspondence, but on which some interesting and suggestive observations have been recorded by MacCormac in the *British Journal of Dermatology and Syphilis* (1937, **49**, 409). From time to time cases undoubtedly due to occupation occur in persons who have for years, perhaps all their working life, been exposed to identical working conditions as regards dust and liquids, yet they have never suffered from skin trouble before. This is sometimes urged by the other side as decisive against its occupational origin. Actually, however, this argument omits one important factor—namely, that the workman has never been the same age before! Like other systems of the body the skin undergoes changes in structure and composition at different periods of life. The skin of an infant is not the same as that of an adult; that of old age differs from that in the prime of life.

It is well known that in many infants who suffer severely from eczema during the early months of life the trouble disappears completely with the oncome of childhood. In common parlance (which sometimes contains more than a grain of truth), "they grow out of it"! Similarly, as age advances and degenerative changes take place in the tissues, skin troubles do arise. May it not be that the sensitivity of the skin to irritants also increases—"they grow into it"? Nor must it be forgotten that "age of tissues" does not always correspond with number of years.—I am, etc.,

Sheffield, Oct. 1. ARTHUR J. HALL.

Psychological Treatment Centres

SIR,—I see among various letters in the *Journal* of October 7 one headed "Psychological Treatment Centres" (p. 743). It does not yet appear to be generally known that some of the pre-war out-patient departments for this purpose have been reopened and new ones are being established in convenient institutions under a Ministry of Health scheme.

Encouragement from M.O.H.s is, of course, very desirable and I am sure will be forthcoming if the preventive aspect is kept in mind, but those who experienced anything of the worst Barcelona air raids declare that the strongest minds get shaken by high explosives, so that much of the work may turn out to be therapeutic rather than preventive, and far from quibbling about methods of psychotherapy perhaps we shall be only too glad to use "any good school."—I am, etc.,

London, N.4. R. F. FIDLER.

Emergency Treatment of Burns

Sir,—I am surprised that the first serious criticism (*Journal*, October 7, p. 745) of the use of picric acid in first-aid posts should come from America. Surely most of us have seen the man who has been incapacitated for many weeks through an extensive dermatitis as the result of the application of picric acid to a small burn which might otherwise have kept him off work for a few days. In burns in children treated with picric acid toxic erythematous rashes are seen even more frequently than in adults, and in a recent series of 400 burns and scalds treated in a children's hospital I have had ample opportunity of dealing with the results of first-aid treatment with this drug.

Like Dr. R. L. Sutton, I appreciate that this method of treatment has not been advocated without careful consideration, but I would be interested to learn of the difficulties in the way of the use of tannic acid, even in relatively unskilled hands. From a fairly extensive personal experience I can fully endorse Dr. Sutton's claims for gentian-violet in hospital practice. Unfortunately, gentian-violet is not always available as a first-aid application, and it may prove unpopular among first-aid workers, whose hands and clothes will certainly become generously stained. Would it not be preferable to use tea in place of picric acid? Tea is available in all houses and in many first-aid posts! The simplest method is to make lumberjack's tea by boiling a handful of tea in a pan of water. The dressing is soaked in this strong solution when cool, and bandaged in position. Adequate cleansing and re-coagulation will of course be carried out in more appropriate surroundings. —I am, etc.,

Glasgow, Oct. 7. Wallace M. Dennison.

Physical Medicine in War Time

Sir,—The letters of Dr. W. Garton (September 16, p. 622), Mr. J. S. Kellett Smith (September 23, p. 664), and Dr. C. B. Heald (September 30, p. 699) have interested me enormously, but they are dealing with the treatment, by physical medicine, of the later results of war injuries.

During 1914 to 1919 I was stationed in Boulogne, and I started physical treatments in a small way at No. 7 Stationary (Officers) Hospital, to which I was then attached, in October, 1915. The work was so successful that, on the suggestion of General Sir Arthur Sloggett, the British Red Cross Society erected and equipped a department, attached to No. 83 General Hospital, with a large treatment room, wards for officers and other ranks, waiting rooms, consulting-rooms, etc., which was opened in June, 1917, and of which I was put in charge. Naturally the type of cases that were referred for treatment were of the milder sort—for example, myalgias (lumbagos, etc.), sciatica, and other neurites and neuralgias, synovitis (chiefly knees), sprains, strains, contusions, the paralyses, aphonias, etc., after shell-shock, and so on. A victim to any of the above is as much *hors de combat* for the time being as one with a more serious wound or illness, and it was found that if such cases were evacuated to England they were usually sent to some small hospital in the country and very little was done for them. By treating them on the spot we found that nearly 80 per cent. were made, and kept, available for military service in France. In other words, there was a genuine economy of man power.

Of course a staff of nurses trained in the administration of physical treatment and of masseurs is necessary, but these are easier to procure now than when I started the department; I had to teach all the nurses myself, but I was fortunate in securing excellent masseurs.

If the war is to go on through the winter it would be well worth considering the establishment of such a department at a base in France without delay. Should the scheme be thought worth considering I have the full reports of the work done in my department, and I should be glad to show them to the proper authorities.—I am, etc.,

Cheltenham, Oct. 2. J. Curtis Webb.

Anaesthesia in War Time

Sir,—Most anaesthetists will agree with your correspondent "G. D. G." who advocates the use of Shipways apparatus for war surgery, and a set of Boyle's bottles make a most excellent Shipway. There is one difficulty, however, in that a set of bellows for the apparatus appears to be unobtainable. I have tried for several weeks in vain to purchase the ordinary Junker bellows. Gas and oxygen, however, appear to be readily available.

I am surprised that attention has not been called to the great value of vinesthene-ether mixture used with an open mask for war surgery. The induction is quick and pleasant, and relaxation can be obtained with light anaesthesia. This appears to be an ideal method for use by students, nurses, and inexperienced anaesthetists.

Finally, I would like to make a very strong plea for the use of gas-and-air analgesia for painful dressing of war wounds. At the Wellhouse Hospital we have used gas-and-air analgesia for all painful dressings since the winter of 1933, and we are deeply impressed with its immense value. The patient is given twenty breaths of gas and air before the dressing is started and the administration is continued during the dressing. Very few patients indeed fail to obtain relief.—I am, etc.,

New Barnet, Oct. 7. John Elam.

Sir,—I have read with amazement a letter from your correspondent "G. D. G." on anaesthesia in war time in your issue of October 7. He advocates the use of chloroform and ether in military surgery and rules out all the newer anaesthetics which have so largely replaced chloroform and ether in civilian practice, greatly to the benefit of the patient. He bases his contention on experiences in the great war and would like us to put the clock back twenty years in order to conform to the practice of that period. He states that in this war we shall be operating on men in a sound physical state, which to my mind is an extraordinary description of men who are likely to be suffering from shock or haemorrhage or toxaemia, and possibly a combination of all three. I have little doubt but that much of the mortality, and particularly the morbidity, of the last war was in fact due to saturating these casualties with protoplasmic poisons such as chloroform and ether.

"G. D. G." refers to modern anaesthetic machines as contrivances. I can only say that that may be how they appear to the uninitiated. Finally, he says that without access to mortality figures one can safely say, speaking from actual experience, that deaths due solely to chloroform or ether were an unknown factor. I quite agree that without mortality figures one might safely say anything.—I am, etc.,

Portsmouth, Oct. 8. G. M. Herriott.

Sir,—May I endorse most strongly all the points made by "G. D. G." (*Journal*, October 7, p. 744). I gave many hundreds of anaesthetics in casualty clearing stations during 1916–17–18, and taught selected sisters as well. I found that using a small brazier's foot-pump for the Shipway (a football bladder made a good reservoir and stabilizer) saved much weariness and left a free hand. The administration of gas and oxygen was possible in static conditions, but fifty bottles of chloroform and ether have only the weight and bulk of one gas cylinder and therefore an immense advantage for mobile and field work.—I am, etc.,

Oct. 8. W. F. B.-S.

Infectious Diseases in War

Sir,—My object in seeking your space is because the work I have been doing in the epidemiological field during the past fifteen years leads me to believe that taking a correlative view of so-called "infectious diseases" instead of considering each to be an entity caused by a specific micro-organism affords greater guidance in preventing and combating them. I imply that so-called "infectious diseases" are acute manifestations of disease caused by microbial invaders. The manifestations of disease produced are identical and are brought about in the same way as when the invaders are physical agents and chemical poisons; because the area in the body which is attacked and the lesion generated are determined by and are the result of the chemico-physical changes undergone by the host's first line of defence (which resides in what I call the protein particles in the plasma). Indeed, most of the signs and symptoms and the majority of the lesions produced are the direct result of the damaged or changed protein particles which develop invasive properties.

For the sake of description, microbial invaders can be divided into those which cause infections from without and from within. The former are more independent, they subject the protein particles to more profound chemico-physical changes, they circulate in the body and enter the lesions that are produced, a more perfect immunity is established against them, they cause relapses and not fresh infections, they are prevented from becoming active with greater ease, and they are better combated with chemotherapeutic than with immunological preparations. The latter reside in the large intestine, which they seldom leave, they develop in cycles, which makes them more active at certain times than at others, they cause fresh infections, they are prevented from being active with great difficulty, and their activity is better combated with immunological than with chemotherapeutic preparations. Micro-organisms which now act as invaders from without are, in my view, either retrogressive or progressive phases of parent forms, which evolved from micro-organisms that entered the intestinal canal with the food, and they began their career as harmless saprophytes. As these changes are continuous there are some micro-organisms which have not yet gained complete independence and others which are beginning to become independent. These two groups of micro-organisms unite the two divisions. The factors which keep these processes dynamic are unfavourable climate, unwholesome food, inadequate elimination of the waste products of food, insufficient air and outdoor exercise, and worry. Man has influence over all these factors with the exception of climate, and were he to use this influence properly the incidence of so-called "infectious diseases" would be reduced to a level which could never be attained with immunological preventive measures.

A so-called war-time "infectious disease," trench-fever, is the result of a number of these factors acting in unison and without necessarily the assistance of micro-organisms to so damage the host's resistance as to make the protein particles act as invaders. So-called venereal diseases are caused by micro-organisms which have completely gained (syphilis) and nearly so (gonorrhoea and soft sore) their independence. The *Vibrio cholerae* has not yet become completely independent, as it is only capable of causing an infection when the time is ripe. The *Pasteurella pestis* is completely independent, and the same may be said of the Spirilla and Spirochaetae. The Rickettsiae invade and cause disease most readily when the proteus group of micro-organisms is active in the intestinal canal. The Clostridia have gained their independence, but they do not cause a manifestation of disease until they have subjected some of the protein particles to a certain chemico-physical change which results in the production of the so-called "toxin." The toxin is a product of the invaded and not of the invader. All the other infections mentioned in your annotation of September 30 (p. 694) are interconnected and they fall into the class of infections from within, they are caused for the most part by mutative forms of the *Bacillus coli communis*, and their activity is responsible for a syndrome to which the name "influenza" can legitimately be given. Some of the causative micro-organisms are sub-phases, or retrogressive forms of the parent micro-organisms; the streptococci, for example, from Friedländer's bacillus. Others are progressive forms like Eberth's bacillus from the *Bacillus suipestifer*. Both of these types of micro-organisms are becoming independent. Friedländer's bacillus plays the greatest part in the production of the common cold and influenza. It is completing a cycle this coming winter, when a severe epidemic may be expected, in the process of which parts may be broken off from the protein particles to which the name "filterable viruses" is given. These filterable parts of the host's main resistance are most readily formed during a pandemic, the next of which may be expected in the winter 1946-7. The streptococci become most active when Friedländer's bacillus is inactive. One of the forms causes scarlet fever, and the changes the protein particles undergo as a sequel are responsible for measles. The retrogressive changes—that is, the development into so-called ultra-microscopic viruses—the protein particles may then undergo cause variola, varicella, herpes zoster, mumps, anterior poliomyelitis, and encephalitis lethargica, whereas the progressive changes, which I call "re-hydration" and "hydration," result in the production of German measles, glandular fever, and the various forms of leukaemia. The activity of the streptococci stimulates the diphtheroid bacilli to develop into the Klebs-Loeffler bacillus, with the possible production of diphtheria. The last war was fought in a non-typhoid era, which partly explains the low incidence of typhoid fever. A new era began in 1930, and as the *Bacillus suipestifer* is growing more active a higher incidence of the infection may be expected in the present conflict to whatever extent preventive inoculation is practised.

Infections from within are not spread by the passage of micro-organisms. A so-called "infectious" individual produces an environment (for want of a better word) an entrance into which by another individual can only result in the latter becoming a victim provided the micro-organism in the colon of the entrant is on the threshold of becoming pathogenic and the main defensive mechanism in the plasma of developing invasive properties. Were more known of the nature of the protein in the plasma the riddle of disease would be solved.—I am, etc.,

London, W.1, Oct. 2. J. E. R. McDONAGH.

Urine Testing by Medical Boards

SIR,—I am sure many medical members of military boards would feel grateful to you for improving the present unsatisfactory arrangements (in fact, their complete absence) whereby recruits are not instructed beforehand of the necessity to enable the board to examine their urines. A large proportion of them empty their bladders just before their arrival, with obvious results. A simple reminder enclosed with the calling-up notice would go a long way to minimize what at times is a serious hindrance to the smooth working of this (at present) most important branch of medical work on a nation-wide scale. A similar suggestion was recently made from the lay side, but for an unknown reason it was not taken due notice of by the respective authority. There would thus appear to be an opportunity for a request by the appropriate medical sources.—I am, etc.,

London, W.10, Oct. 3. G. DE SWIET.

Evacuation

SIR,—The outspoken remarks by Dr. I. C. Keir in your issue of October 7 (p. 745) on the need for education in "the rudiments of personal cleanliness, self-respect, and (incredible as it may seem) the use of a lavatory" should be a source of inspiration to the Board of Education and the Ministry of Health. It is well known that personal hygiene is not on the syllabus of the training colleges. It is easy to understand, therefore, why it is not in the curricula of the schools. The parents have been compulsorily educated for some three generations, and have learnt to ignore the necessity of this subject as one that should be taught, so they are unable to instruct their children. Dr. Keir has opened our eyes to the gap in our learning. May it be hoped that those who are in power will see that it is filled.—I am, etc.,

London, W.1, Oct. 7. OCTAVIA LEWIN.

"Black-out" Problems

SIR,—There is an urgent problem which calls for solution if the health of our civilian population is not to be seriously affected—the maintenance of a "black-out" which excludes light without excluding fresh air. Many people are now spending long periods in rooms inadequately ventilated. The periods will be longer in the darker days of winter. Already one has only to travel in public vehicles and mix with one's fellows to see that a number of people are suffering from colds. What effect will present conditions have on the spread of pulmonary tuberculosis and other infectious diseases as well as on the general health? The rationing of coal, gas, and electric light will affect the problem of heating. Inadequate illumination affects eyesight. "Blacking out" is not easy, and such blacking out as can be quickly replaced (for example, at night if removed for sleep) calls for special methods. There must be many methods for meeting the problems of ventilation, heating, and eyestrain, so I write to "ventilate" the subject.—I am, etc.,

London, W.1, Oct. 6. M. E. Ormsby.

Urethrography

Sir,—Perhaps the authors responsible for the coinage of that inelegant word "urethrography" may be permitted to make a few comments on the article under this title by Mr. James Kemble in the *Journal* of September 30 (p. 683).

In our work, which was described in a monograph entitled *The Radiographic Examination of the Male Urethra,* we had neither the advantages of the modern hot cathode tube nor of the fluid type of lipiodol. Radiographic technique has made great strides since 1925. But the experience which we gained in breaking new soil may be of some value in developing the theme on modern lines. It is impossible to obtain a satisfactory radiograph of the filled prostatic urethra unless the exposure is made while the opaque fluid is actually passing along this segment at the critical moment. To accomplish this a *constant stream* must be flowing through the urethra into the bladder. The use of a glass syringe was found to give good results in some cases, but it was discarded in favour of a simple manometric method which was much more positive. By employing this technique the whole urethra, anterior and posterior, and the bladder base are shown simultaneously on one film.

The dorsal position of the patient was used in the first experiments, but was given up in favour of the ventral position. With the patient supine, unless the rectum is quite empty the base of the bladder will receive impressions which simulate those normally produced by intravesical projection of the prostate. In the prone position this source of error is eliminated. Also, as the urethra is relatively anterior, a film placed next to the pubis will give sharper definition than one under the buttocks. Injection with the patient prone is quite simple. Lastly, a film taken after evacuation of the opaque fluid from the bladder is of definite value as an index of the amount of residual urine. Urethrography has found a place in some of the leading urological textbooks in America, and it is encouraging to find evidence of renewed interest being taken in the method on this side of the Atlantic.—We are, etc.,

Paul Cave.
London, W.1, Oct. 3. G. L. S. Konstam.

Manzullo's Tellurite Test for Diphtheria

Sir,—In your issue of June 24 (p. 1291) you wrote concerning some recent Manzullo tests, "Reliance on the test would deprive one case in six of necessary immediate serum treatment and lead to the unnecessary administration of serum to nearly 50 per cent. of non-diphtheritic cases."

It seemed to be of interest to discover how the test acted in Dublin. By the kind permission and with the help of Dr. C. J. McSweeney, the medical superintendent, I applied the test to seventy-five unselected patients admitted to Cork Street Hospital with pharyngeal exudate. Forty-three patients diagnosed as diphtheria and positive on culture yielded thirty-eight positive and five negative M (Manzullo) results; eleven "clinically doubtful," confirmed by culture, yielded two negative M results; seventeen cases of follicular tonsillitis gave six positive and eleven negative M results; while four cases of Vincent's angina all showed deep blackening—that is, positive M results. Thus in fifty-four diphtheria patients seven (13 per cent.) gave a false M negative result, while among thirty-one non-diphtheria patients ten (33 per cent.) gave a false positive. These figures for Dublin agree fairly closely with those in your note.—I am, etc.,

J. G. Tynan, M.B.,
Dublin, Oct. 5. Assistant Medical Officer, Cork Street Hospital.

Medico-Legal

DRUG ADDICT'S POSE AS DOCTOR

William Arthur Young, a morphine addict, at the end of July called on a Hampstead doctor and said that his name was Alexander McLean, that he was a doctor from Canada, and that four years ago he had had a serious operation, as a result of which he was in great pain. He asked for a prescription for morphine. The doctor found scars confirming his story and prescribed for him. Next day Young returned, saying that the prescription had been ineffective, and asked for another. He appeared to have a good knowledge of the medical profession, and the doctor gave him a prescription for 5 grains. A few days later he called again, saying that he had accidentally dropped most of the tablets down the sink. He obtained a prescription for 5 grains more. Next day he borrowed 10s. As he did not return the doctor made inquiries, and when Young came back ten days later asking for another prescription he was arrested and charged with unlawfully possessing 10 grains of morphine. He had on him a syringe and five needles.

Young pleaded guilty and told the court (*Times*, August 28) that he had called on other doctors and got prescriptions for morphine. The authorities stated that he had obtained 74 grains from eight different doctors at Brighton in nine weeks, and that at other towns he had collected 1½ grains a day during May. He had had five previous convictions. He had trained as a male nurse. Mr. L. R. Dunne, the stipendiary magistrate, sentenced him to twelve months' imprisonment, saying that his only possible chance was to be placed somewhere where he could not get drugs and would receive medical attention to fortify him against the craving for them.

Universities and Colleges

UNIVERSITY OF OXFORD

A decree was approved in Congregation on October 6 permitting any member of the University during the period of the present emergency to supplicate for a degree in absence on any degree day provided he has received permission from the Vice-Chancellor and Proctors on the grounds that he was prevented from taking the degree in person by reason of military service or other such urgent cause.

UNIVERSITY OF CAMBRIDGE

For the present the University Library will be open on weekdays from 9 a.m. to 1 p.m. and again from 2.15 p.m. until 4 p.m.; on Saturdays from 9 a.m. to 1 p.m. only. During the winter months it will be necessary owing to lighting restrictions to close at 3.30 p.m.

UNIVERSITY OF ST. ANDREWS

At a graduation ceremony held on October 6 the honorary degree of LL.D. was conferred upon William Graham Campbell, M.B., C.M., L.D.S., lecturer in orthodontics in the University of St. Andrews.

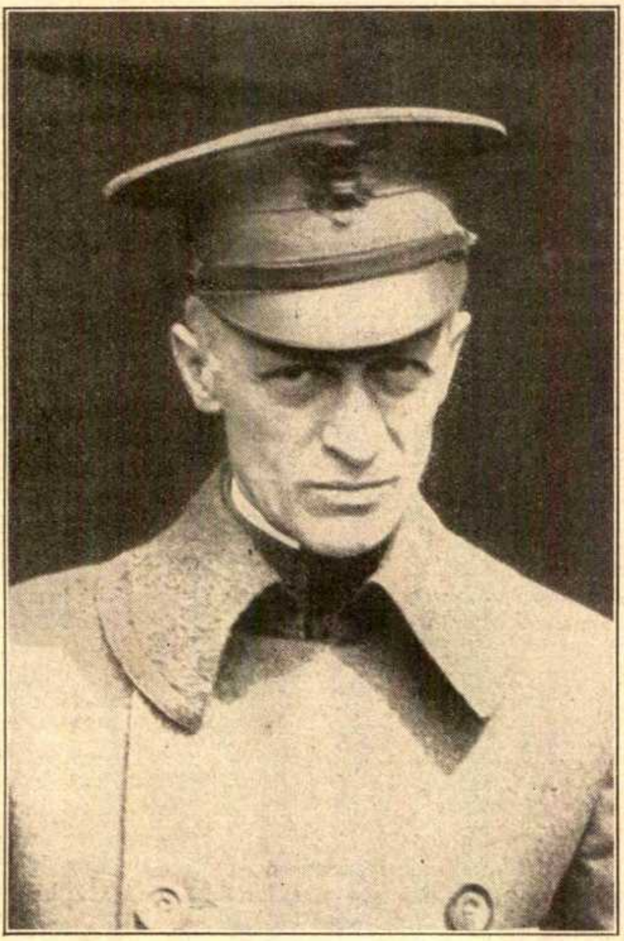
ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

At a meeting of the Royal Faculty of Physicians and Surgeons of Glasgow held on October 2, with Dr. John Henderson, President, in the chair, the following were admitted Fellows of Faculty: Anne Cunningham Aitkenhead, M.B., Ch.B., David Clowes Williams, M.B., Ch.B.

Obituary

HARVEY CUSHING, C.B., M.D.
Hon. F.R.C.P., F.R.C.S.

We record with deep regret the death at Newhaven, Connecticut, on October 7 of Professor Harvey Cushing, the great American surgeon who was a Foreign Member of the Royal Society, a Foreign Corresponding Member of the British Medical Association, and an Honorary Fellow of the Royal College of Physicians of London and the Royal College of Surgeons of England. Harvey Williams Cushing was born on April 8, 1869, at Cleveland, Ohio; his brother E. F. Cushing (1862–1911), professor of paediatrics, his father Henry Kirke Cushing (1827–1910), professor of obstetrics and gynaecology in the Western Reserve Medical School, his grandfather Erasmus Cushing (1802–93), who came to Cleveland from Massachusetts in 1835, and his great-grandfather David Cushing, jun. (1768–1814), were medical men. His mother's family—the Williamses—migrated before 1812 from Connecticut to Ohio to create the "Yale of the West." Brought up among the traditions of the Western Reserve it was thus not unnatural that he should graduate in Arts at Yale and during his busy life return to Cleveland in reminiscent mood on ceremonial occasions, among them the dedication of the new medical buildings of the Western Reserve University (1924) and the Allen Memorial Medical Library, Cleveland (1926).



Johns Hopkins Hospital

Like W. S. Thayer, educated medically at Boston (M.D.Harvard, 1895), and a resident at the Massachusetts General Hospital, Cushing followed him to the Johns Hopkins Hospital, Baltimore. Here he probably made the final decision between the career of a physician or a surgeon; this must have been difficult for the only man except King Edward VII, when Prince of Wales, to become in later life an honorary fellow of both the Royal College of Physicians of London and the Royal College of Surgeons of England. But in an address on "The Physician and the Surgeon" (1922) he took as his text the dictum of Lanfranchi (d. 1315) that "no one can be a good physician who has no idea of surgical operations, and a surgeon is nothing if ignorant of medicine." In the Hunterian Laboratory of experimental medicine at the Johns Hopkins he worked quietly for years at experimental surgery and pathology, becoming associate in surgery in 1899 and associate professor of surgery in the University 1903–12.

Neurological Surgery

In 1905 he decided to restrict his professional activities to neurological surgery, and in that year gave an address on "the special field of neurological surgery" at Cleveland, and wrote on "comparative surgery, a new development in the teaching of operative surgery." In 1912 he was appointed Moseley Professor of Surgery in Harvard University and surgeon-in-chief to the newly opened Peter Brent Brigham Hospital, Boston, Mass., where in the next twenty years (1912–32), perhaps the most actively productive period of his life, he built up a great school of neurosurgery. For his seventieth birthday L. Eisenhardt, J. F. Fulton, and M. E. Stanton prepared his bibliography for the Cushing Society; this showed that he had written three hundred and thirty papers, addresses, and reports, and that almost exactly the same number (327) of papers had been contributed from his clinics and laboratories by his pupils. In 1912 the first of his thirteen published books appeared, the great monograph *The Pituitary Body and its Disorders: Clinical States produced by Disorders of the Hypophysis Cerebri*. This was the stimulating foundation for the widespread research work on the pituitary, and led up to his syndrome of pituitary basophilism known as Cushing's syndrome (1932). His other professional works were mainly on various forms of cerebral and intracranial tumours.

War Service

In March, 1915, Cushing left Boston for France with the Harvard Unit to serve in the American Ambulance at Neuilly, and after working there and seeing the organizations of the French and the Royal Army Medical Corps returned to Boston. In March, 1917, he took a very active part in organizing the United States Army Base Hospital No. 5, and in May sailed again as its Director for France. He became an operating surgeon with the British Expeditionary Force, and in June, 1919, was transferred to the medical headquarters of the American Expeditionary Force as senior consultant in neurosurgery. In October, 1918, he became seriously ill with acute polyneuritis, but recovered sufficiently to reach England in the middle of January, 1919, and the United States on February 20. *From a Surgeon's Journal, 1915–1918*, stated to be edited anonymously, and not published until 1936, contained his diary of his arduous war service.

Cushing's Life of Osler

Early in 1920 Lady Osler asked Cushing to write the life of Sir William. This labour of love was completed in 1925 and published by the Clarendon Press at Oxford. One of the best medical biographies and, like Sir Rickman Godlee's *Lord Lister*, by a surgeon, it gave a wonderful picture of a great personality, and was described as "the happiest fusion of the objective and subjective that biographical art has ever turned out in our rich literature" (Arnold C. Klebs). It was remarkable for the absence of Cushing's name from the text and index. It was, however, mentioned that on the day the Oslers finally left Baltimore "someone unscrewed and took away the unpretentious 'Dr. Osler' door-plate." This relic, it may be added, afterwards reposed on Cushing's writing-desk.

The first four chiefs of the Johns Hopkins Hospital—Welch, Osler, Halsted, and Kelly—greatly influenced the generation they so successfully trained up to follow the Hopkins tradition which they created. Of their pupils many became famous, and particularly Cushing, who certainly resembled Osler in personality, mentality, generosity in giving help and credit to others, in power of work and of self-effacement. Like Osler, he died a few months after his seventieth birthday had been enthusiastically celebrated by his friends and pupils. He had the same keen interest in medical bibliography, history, and book collecting. As a writer he had a clear, concise, and allusive style; for instance, at the Lister Centenary celebrations at Edinburgh in 1927 he compared Abraham Lincoln and Lister "in their service to the proposition that all men are created equal. Lister freed man from the shackles of sepsis; Lincoln, a race from those of slavery."

Cushing deservedly received many honours in Europe as well as in America; for war services C.B.(Mil.) and the Legion of Honour; a Foreign Member of the Royal Society, twenty-one doctorates from universities, and many honorary memberships of scientific and medical societies. In 1913 he was selected to give the address in surgery entitled "Realignments in Greater Medicine: their Effect upon Surgery and the Influence of Surgery upon them," at the seventeenth and last International Congress of Medicine held in London. He was then 44 years of age; the reader of the address in medicine, on "Medical Prognosis: its Methods, its Evolution, its Limitations," was Professor A. Chauffard (1855–1932) of Paris, being fourteen years his senior.

When in 1932 Cushing's time at Boston came to an end he returned to Yale as Sterling Professor of Neurology (1933–7) and consulting neurologist to the New Haven Hospital, and on account of failing health gave up the Sterling chair to become director of studies in the history of medicine.

Humphry Rolleston.

Harvey Cushing at Home

Sir Arthur MacNalty sends the following account of "A Day with Dr. Harvey Cushing," written after his visit to the United States this year, and adds a personal tribute:

On June 26, 1939, I went by train from New York to New Haven, Connecticut, and proceeded to the New Haven Hospital, where I found Harvey Cushing working in his room. There he was, clad in a grey suit, with his clear-cut classical features like a Roman cameo, his figure as slight and upright as that of a young man, his keen eyes lit up and his face smiling a welcome to me. Papers and casebooks were on his desk, the shelves behind him were lined with books, surgeons and house-men in white coats and attentive secretaries formed his suite. With a few words of instruction he dismissed the suite and we sat down to talk. His serious illness two years ago had given his friends cause for considerable anxiety, and I was glad to find him in good health and as mentally alert as of yore. He had recently celebrated his seventieth birthday by bringing out a large book on *The Meningiomas*, in which he records the after-histories of his cases and his wealth of experience as the leading cerebral surgeon of the world to-day. He expressed his gratification at the Honorary Fellowship which the Royal College of Physicians had recently conferred upon him. "I never expected such an honour," he said with a twinkle in his eyes; "it makes me a sort of professional hermaphrodite, physician and surgeon too!"

He is now professor emeritus of Yale University and consulting neurologist to the New Haven Hospital, where he has rooms, laboratories, and full facilities for continuing his own neurological investigations and for directing and inspiring younger workers in the same field. Neither does the biographer of Osler forget his literary activities. He told me he was writing a bibliographical life of Vesalius on which he had been collecting material for forty years, the subject being originally suggested to him by Osler. After showing me his laboratories and the work on which he is engaged, Dr. Cushing introduced me to his colleague, Dr. Zimmerman, who described to me his research work on encephalitis lethargica. Dr. Cushing then took me to his delightful New England house with a wide veranda in front and approached like an English mansion by a carriage-drive. On the way we passed the Gothic grey stone buildings of Yale University set in green sward. Yale is very much the Oxford or Cambridge of the United States, and I was informed that in recent years the system of colleges has been introduced, which brings it even closer to the parent universities of England.

Dr. Cushing had invited four Yale professors, in whose work he knew I would be interested, to meet me at luncheon. These were: Dr. George Blumer, clinical professor of medicine; Dr. George H. Smith, professor of anatomy; Dr. Ira Hiscock of the public health department; Dr. Middleton C. Winternitz, professor of pathology. At luncheon we had a most interesting conversation which ranged over many subjects: Osler, Welch, the present condition of Johns Hopkins University, progress in public health in the United States, and advances in our knowledge of epidemic diseases of the central nervous system. Dr. Cushing showed me his vast library, which contains a number of rare editions of medical authors of the fourteenth, fifteenth, and sixteenth centuries. He possesses one of the most complete collections in the world of the works of Vesalius. We then left Dr. Cushing to take a siesta and the professors took me to the Medical University buildings to see something of the research work in progress there. I then returned to the New Haven Hospital and had the pleasure of a long talk with Dr. Cushing on public health work in the United States. Dr. Cushing strongly holds the view that social health legislation in the United States must be gradually built up, and that a revolutionary scheme would defeat its own objects and might antagonize the medical profession. Dr. Cushing with his wonted courtesy insisted on seeing me off by the evening train to New York.

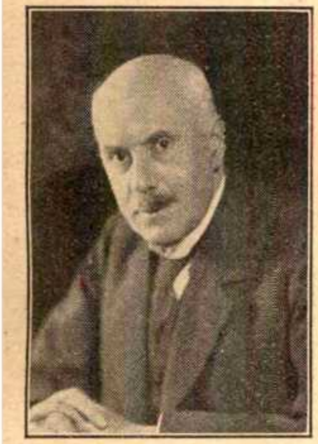
Now those hands which wielded pen and scalpel with equal skill are at rest and the great name of Harvey Cushing passes into history. A fortnight ago I received a last gift from him, the bibliography of his writings, prepared on the occasion of his seventieth birthday by the Harvey Cushing Society. Eighty-nine pages of close print are barely sufficient to record the work which he did for the advancement of cerebral surgery, of knowledge of the endocrines, and of neurology generally. His biography of Osler is a classic, the wonderful tribute of one leader to another. As my little sketch of that pleasant day at New Haven shows, Harvey Cushing was investigating and working up to the end. It was a full and glorious life, and we who loved and admired him will ever find joy in his remembrance.

[The photograph reproduced is by the "Topical" Press Agency, Ltd.]

JOHN DIXON COMRIE, M.A., B.Sc., M.D.

Physician to the Royal Infirmary, Lecturer on the History of Medicine in the University, and Vice-President of the Royal College of Physicians, Edinburgh

We regret to announce the death of Dr. John D. Comrie, on October 2, at his home in Manor Place, Edinburgh.



John Comrie was born at Peterhead, Aberdeenshire, where his father practised, on February 23, 1875. An only child and the son and grandson of medical men, it was not unnatural that medicine should become his calling. When his father retired he came to live in Edinburgh, and it was at George Watson's College and at the University of Edinburgh that Comrie received his undergraduate training, taking degrees in Arts, Science, and Medicine, the last with first-class honours. After holding appointments as resident physician and surgeon in Edinburgh and Glasgow he spent a year in London as clinical assistant with Sir David Ferrier at the National Hospital, Queen Square, and with Mr. Marcus Gunn at Moorfields. The following winter he devoted to pathology, working in the laboratory of Professor Virchow in Berlin and that of Professor Obersteiner in Vienna. Returning to Edinburgh in 1902, Comrie engaged for a time in general practice, but for many years past he had practised as a consulting physician. Among successive appointments which he held were those of clinical tutor, assistant pathologist, and assistant physician to the Royal Infirmary. In 1927 he was appointed a full physician, and at the time of his death he was the senior physician to this institution. For a period he was pathologist to Leith Hospital, and for several years he was physician to the Deaconess Hospital, Edinburgh. From 1921 onwards he delivered a course of lectures on the practice of medicine in the School of Medicine of the Royal Colleges. In 1909 he was appointed to the newly instituted lectureship on the history of medicine, a post which he filled with distinction up to the time of his death.

A man with an essentially academic outlook, Comrie had a variety of interests and activities. He was a prolific writer, publishing among other works a book on *Diet in Health and Sickness*. In 1912 he inaugurated, as general editor, the Edinburgh Series of Medical Textbooks, and a little more than a year ago he was appointed Editor of the *Edinburgh Medical Journal*. But it is especially as a learned medical historian, for in this province he had a wide reputation, that Comrie's name will live in the annals of the Edinburgh School. Here his familiarity with the dead languages served him in good stead. *A History of Scottish Medicine*, a second edition of which appeared in two volumes, was a contribution of special importance.

Comrie was an enthusiastic Territorial. During the great war he was in charge of wards at the 2nd Scottish General Hospital; later he served in France as lieutenant-colonel of a large medical division in a general hospital; and in 1919 he accompanied the British Expeditionary Force to Northern Russia as consulting physician.

The British Medical Association had in Comrie a keen supporter. He presided over the Section of the History of Medicine at the Annual Meetings in 1927 and 1930, and for many years he had been an active worker both on the Council of the Association and on the Journal Committee. At the time of his death he was chairman of the Scottish Committee, the Scottish Central War Committee, and the Consultants and Specialists Group Committee for Scotland.

There was something very likeable about John D. Comrie. His figure was imposing, his manner unassuming, somewhat hesitating, almost prim. He had a kindly outlook and was a friendly fellow. All who knew him will recall the characteristic twinkle so often in his eye, an accompaniment of a very pawky humour. He was a *persona grata* with his colleagues not only in *res medica* but at the festive board. Dogged at times by indifferent health, the way in which he stood up to his disability and the handicap which it imposed evoked their admiration.

To his widow, the daughter of the late Mr. Archibald Hewat, and to his three daughters we offer our sympathy.

E. B.

[The photograph reproduced is by Elliott and Fry, Ltd.]

Dr. Ganesh Sawh writes: As a former President of the Edinburgh West Indian Students' Society, I wish to place on record the sincere regret that will be felt by all West Indian graduates who, during their Edinburgh career, came into contact with the late Dr. John D. Comrie. He understood the problems of students from the far-off Colonies, and was always kind and sympathetic towards them. As a lecturer in systematic medicine and a teacher of clinical medicine his fame was well known to all West Indians, and they would flock to attend his lectures and clinics. Within my knowledge no West Indian student would have considered his medical education complete had he not at some time attended the clinics of the late Dr. Comrie. He was often acclaimed by them as one of the best clinical teachers of their time. Dr. Comrie has set an example which it will be difficult for others to follow. The excellence of his teaching will, however, bear fruit in the gardens of the West Indies, where many Edinburgh graduates will reflect on the soundness of their early clinical training under a master in the art of teaching.

We regret to announce the death in his sixtieth year of **Dr. Charles Michael Roberts** on September 2. He was born in India and came at an early age to England, where he was brought up. Roberts received his medical education at St. Thomas's Hospital, where he obtained the first entrance scholarship in natural science. Qualifying M.B. in 1904 and B.S. in 1906, he entered the Indian Medical Service in 1907, but left it in 1908 to buy a practice in Woking. He took up *x*-ray work shortly before the last war, joining the R.A.M.C. in 1915, and was with various hospitals in France and Salonika until 1919. He became a clinical and later a chief assistant in the *x*-ray department at St. Bartholomew's Hospital, a post he eventually gave up on account of failing health. He was supervisor to the British Red Cross Society Curative Post, Woking, and was also radiologist to the Victoria Hospital, Woking. His kindly, cheery personality will be very much missed both by his colleagues in London and Woking and by those who knew him well. He leaves a widow, three sons, and a daughter.

Dr. **John McFarlane William Pollard** died suddenly at Cheltenham on September 26. He was a student at Guy's Hospital, and obtained the D.P.H. of the English Conjoint Board in 1912; before this he had graduated M.B., B.S.Lond. and taken the M.D. degree in tropical medicine. After serving as resident medical officer to the Central London Ophthalmic Hospital he took the certificate of the London School of Tropical Medicine and then joined the Nigerian Medical Service, of which he became assistant director. Dr. Pollard was elected a member of the British Medical Association in 1907, and was a Fellow of the Society of Tropical Medicine and Hygiene. Since his retirement from the

Nigerian Medical Service in 1928 he had held the post of honorary refractionist to the Cheltenham Eye, Ear, Nose, and Throat Hospital.

Dr. Walter Edward Turner died on September 28 in his sixty-sixth year at Eton House, Hanging Langford, near Salisbury. He studied medicine at St. Mary's Hospital, and took the M.R.C.S. and L.R.C.P. diplomas in 1900. Dr. Turner was for many years medical superintendent of the Central Middlesex County Hospital, and in 1932–3 served as chairman of the Willesden Division of the British Medical Association. He retired from his post at the Central Middlesex County Hospital on account of ill-health at the end of 1935, and was succeeded by Dr. H. Carter.

Dr. Margaret Scoresby-Jackson, elder daughter of the late R. E. Scoresby-Jackson, M.D., F.R.S.Ed., died on September 29 at Worthing. She studied for the profession at the London School of Medicine for Women, at University College Hospital, and at the University of Durham College of Medicine, Newcastle-upon-Tyne, and graduated M.B., B.S. at Durham in 1924, proceeding to the M.D. two years later. She had been clinical assistant in the out-patient department at the Bethlem Royal Hospital, with care of mental defective patients, and clinical assistant in the neurological department at Guy's Hospital, and contributed to the *Journal of Mental Science* in 1927 a paper on the fragility of the red blood cells in mental disease. Dr. Scoresby-Jackson was a member of the British Medical Association and the Medical Women's Federation, and a Fellow of the Royal Society of Medicine.

Dr. Francis John Russell died at his home in Lee Road, Blackheath, on September 30. A student of the London Hospital he qualified M.R.C.S., L.R.C.P. in 1905, and was a member of the British Medical Association for most of his professional life. At the close of 1937 he was appointed emergency officer for making the arrangements for war-time service among the medical men of Greenwich and Deptford, and did a considerable amount of clerical and other work in this respect early last year.

Dr. John Allison, who died suddenly on October 1, aged 76, at Kettering, Northants, had been a member of the British Medical Association for forty-seven years, and in 1899 was president of the South Midland Branch. Educated at the University of Edinburgh, he took the M.B. and C.M. degrees in 1886, and proceeded M.D. in 1895; in the following year he obtained the diploma of F.R.C.S.Ed., and in 1900 the D.P.H. of the English Conjoint Board. After graduating he served as resident surgeon at the Edinburgh Royal Infirmary, and became a Fellow of the Obstetrical Society of Edinburgh. At Kettering he held for many years the post of medical officer of health to the urban district council and honorary surgeon to the Kettering General Hospital. He held a commission in the R.A.M.C.(T.), and attained the rank of lieutenant-colonel.

The death took place on October 1 at Surbiton of Dr. George Frederick Cooper, formerly of Longcroft, Loughton, at the age of 78. He studied medicine at St. Thomas's Hospital, and after taking the M.R.C.S. and L.R.C.P. diplomas graduated M.B., B.S.Lond., with a gold medal, in 1884. At St. Thomas's he served as house-surgeon and resident accoucheur before making his home in Chile, where he obtained the M.D. degree at Santiago in 1886 and became medical officer to Pisagua Hospital and the Nitrate Railways, Tarapaca. Dr. Cooper joined the British Medical Association in 1885 and remained a member up to the time of his death.

The following well-known foreign medical men have died: Dr. Albert Brault, honorary physician to the Paris hospitals and member of the Académie de Médecine, aged 88; Dr. Valentin Cantinieaux, the Belgian urologist; and Dr. Francis Hoeffer McMechan, an anaesthetist of Cincinnati, honorary member of the Section of Anaesthetics of the Royal Society of Medicine, and editor of several journals of anaesthesia.

Medical Notes in Parliament

On October 9 Mr. Oliver Stanley presented a Bill to prevent the price of goods of such descriptions as might be specified by the Board of Trade being raised above a basic price by more than an amount referable to increases in certain specified expenses. The Bill was read a first time.

Health of the Evacuated Population

Dr. Summerskill asked on October 5 whether, in determining a suitable reception area for children in country districts, investigations were made concerning the cleanliness and safety of the local milk supply. Dr. Elliot replied that the primary considerations in determining the reception areas had to be those of transport and accommodation. Such consideration as was possible was given to other relevant factors, including any abnormal risks from infectious disease from food and water supplies, as ascertained from public health and other reports.

Dr. Elliot told Sir Waldron Smithers on October 5 that his attention had been called to the condition of evacuated children suffering from various diseases, including whooping-cough, impetigo, scarlet fever, and verminous heads. He had drawn the attention of local authorities to the matter in a circular recently issued on public health services in the reception areas. Arrangements were being made for the medical inspection in the evacuating areas of the smaller numbers of school children now being moved under the Government scheme.

In answer to Sir Charles Cayzer, Dr. Elliot said he had instructed evacuating local authorities before dispatching any further parties to the reception areas to carry out a medical inspection and, where necessary, the efficient treatment of all children to be included in the parties.

Mr. Butcher asked on October 5 whether, in order to alleviate hardship and suffering to unaccompanied children coming from evacuation areas, the Board of Education would authorize medical officers of health in reception areas to provide dental, orthopaedic, and ophthalmic treatment in cases of special need without the consent of the parents. Mr. Kenneth Lindsay answered that as regards dental treatment the Board was advised that where there was evidence that the child had received such treatment in the past it might be assumed that the parent would agree to further treatment, but that the administration of a general anaesthetic should, if at all possible, be avoided unless the consent of the parent had been obtained. In other dental cases treatment should be limited to emergency treatment. Cases requiring immediate orthopaedic or ophthalmic treatment were likely to be rare, and except in such cases the consent of the parent should be obtained.

Dr. Elliot will consider whether in special circumstances, such as when a doctor certifies that it is advisable, facilities can be arranged to enable parents to visit their children in reception areas in cases of illness.

Doctors and First-aid Posts

Sir Francis Fremantle asked Dr. Elliot on October 4 if his attention had been drawn to the absence of arrangements for the continuous medical supervision of first-aid posts and for the continued training of the first-aid parties attached to such posts; and what action he proposed to take. Dr. Elliot replied that arrangements were made before the outbreak of war whereby a medical officer attached to each first-aid post undertook for an annual fee to conduct the collective training of the personnel of the post under the general supervision of the medical officer of health. These arrangements were still in operation.

Sir Francis Fremantle contended that what was now required called for an infinitely greater amount of work than in peace. He said medical officers could not attend without further remuneration. Dr. ELLIOT remarked that he would later in the week receive some doctors who took part in the organization of first-aid posts.

Doctors released from E.M.S.

Sir FRANCIS FREMANTLE inquired on October 4 whether Dr. Elliot would arrange for medical practitioners now engaged for duty in hospitals wholly or partially empty to be released for civil practice with liability to immediate recall in case of need. Dr. ELLIOT replied that he would do so. Letters had been sent to a number of whole-time members of the Emergency Medical Service offering to release them for civil practice under certain conditions.

Increased Drug Prices

Mr. DAVID ADAMS asserted on October 5 that since the outbreak of war vegetable drugs, essential oils, and medicinal chemicals had doubled and even trebled in price, and that certain of these were being withheld altogether from the market. Mr. OLIVER STANLEY replied that he found there had been substantial increases in the price of a number of goods of this class. Inquiries were being actively pursued, and discussions had been arranged with representatives of the wholesale and retail drug trades.

Proprietary Medicines: Postponement

On October 5 Dr. ELLIOT recalled that Sir John Simon announced on August 4 that it was intended to appoint a committee to examine both the control and the taxation aspects of the proprietary medicines question. Dr. Elliot said that in view of the outbreak of war the appointment of the committee had been postponed. The question of legislation must remain in abeyance.

Paying for Billeting

It was announced in Parliament last week that a proportion of the cost of billeting evacuated school children is to be recovered from parents. The average cost to the Government at present is roughly 9s. a week for each child. Parents or other persons responsible for evacuated children will be asked to pay the full charge of 9s. if they can afford to do so, but the Government recognizes that in many cases there will not be a corresponding relief to the family budget, and they have accordingly fixed a contribution of 6s. a week as the standard charge. Parents who cannot afford to pay as much as 6s. will pay a smaller amount appropriate to their means. The date on which liability to pay starts is fixed for October 28.

Excess Profits Tax and the Professions

In Committee of the House of Commons on the Finance Bill on October 5 Sir HENRY MORRIS-JONES opened a discussion on the clause imposing an Excess Profits Tax. He said there was no reason why any individuals who got an accretion of their income during the war should escape this additional taxation.

Sir JOHN SIMON said there was attractiveness in the argument that this tax should include the professions, but if it were applied to all individuals it would be a third general tax. A person starting in the practice of a profession might find his income at the beginning was materially less than it would become in the course of years of successful practice. There was no justification for treating that man as having made excess profits.

The clause was agreed to and the committee stage was completed.

Institutional Treatment of Tuberculosis

Captain PLUGGE asked what arrangements were being made to continue the treatment of consumptives who had been moved from the institutions in which they were receiving treatment. Dr. ELLIOT replied on October 9 that any consumptive requiring institutional treatment should receive it. Accommodation was available for such treatment. He was investigating the question of releasing certain hospitals and sanatoria from the Emergency Scheme altogether.

School-leaving Age

In the House of Commons on October 9 the Education (Emergency) Bill, which has passed the House of Lords, was read a second time. Mr. KENNETH LINDSAY, who moved the second reading, said that the Bill suspended the raising of the school age from 14 to 15. This would otherwise have taken effect on September 1 last under the Education Act of 1936. In all the evacuation areas and most of the neutral areas schools were still closed. In the reception areas, where the schools were working a double-shift system or some other expedient, there was very great difficulty in providing the sort of education visualized between the ages of 11 and 15 when the legislation was passed. The building operations to meet the requirements of reorganization were held up by the prior claims of the Services and supply departments, and the procedure of granting exemptions also could not possibly be worked at present. After the war the Government would review the whole position. This was a Bill for suspension, and not for repeal.

If compulsory schooling was to finish for the time being at 14, they had done what they could to counteract what was admittedly a step back by setting up a new body called the National Youth Committee, whose declared object was to safeguard the educational and recreational interests of young workers between 14 and 18. That was being done immediately, and might help to remedy some of the conditions, particularly in the evacuation areas. At one place in Surrey the whole dietary of a group of evacuated children had been planned, and included fruit and vegetables on a scale which the children had never seen before. The Department proposed to exploit this situation to the full and to make the most of this period.

The Education (Emergency) (Scotland) Bill, which postpones the raising of the school age in Scotland, was read a second time on the same date.

Milk Grants.—On October 2 Sir REGINALD DORMAN-SMITH informed Brigadier-General Clifton Brown that the Milk Industry Act, 1939, which provided for the payment of quality premiums in respect of tuberculin tested and accredited milk and milk from attested herds, remained in force, and the premiums would accordingly continue to be paid for those categories of milk by the Milk Marketing Board. The premiums were independent of the bonus payable under the Tuberculosis (Attested Herds) Scheme.

Medical Attention for Dependants of Men on Service.—On October 3 Dr. ELLIOT told Mr. Dobbie that medical assistance was available at the cost of Service funds for the wives and families of regular soldiers and certain classes of reservists if they were living at or near a Service station. A similar privilege existed in the R.A.F. Apart from these special provisions the medical services provided for the population generally were, of course, available wherever and whenever they were required.

Dietary of School Children.—Mr. KENNETH LINDSAY remarked on October 5 that there was still scope for considerable improvement in the meals provided for necessitous undernourished school children. It was not the case that the normal present diet consisted of meat, potatoes, and dried vegetables. Under normal conditions fresh fruit was recommended as an essential when planning the dietaries. Local education authorities were advised that each midday meal should include either fresh fruit or fresh vegetables. The inclusion of dishes made with cheese was also recommended.

Gas-and-oxygen for War Wounds.—On October 10 Dr. SUMMERSKILL asked the Secretary of State for War if he would advise the medical staffs of military hospitals that whenever possible they should use gas-and-oxygen analgesia in the dressing of war wounds of a severe character. Mr. HORE-BELISHA replied that he was advised that the medical staff of military hospitals were fully aware of the value of this treatment, and would use it in all appropriate cases.

Inspection of Factories in War Time.—Sir JOHN ANDERSON said on October 5 that the work of the factory inspectors generally was necessarily abnormal in many respects at the present time, though still closely related to their normal function of watching and advising on the safety, health, and welfare of factory employees. Arrangements were made early in the year for the inspectorate to devote much of their time to assist in the launching of the provisions of the Civil Defence Act as to air raid shelter in factories. It was hoped that this work would shortly be completed. The strength of the inspectorate was being kept under review, and some additional appointments were being made.

Notes in Brief

Through the Swiss Minister in London the German Government has given an assurance that it will abide by the Geneva Protocol of 1925 prohibiting the use of gas and bacteriological methods of war provided that the British Government will also observe the Protocol.

No special provision has been made to attach to the staff of the Ministry of Information persons connected with the medical press. The Minister of Health will be responsible for all publicity necessitated by the work of his Department.

Medical News

As from Monday, October 16, 1939, the Library of the British Medical Association will be open from 9.0 a.m. to 5.0 p.m. (1.0 p.m. Saturday) until further notice.

The Governing Body of the British Postgraduate School at Hammersmith has decided to carry on postgraduate instruction for the present.

The West End Hospital for Nervous Diseases, at its out-patient department (73, Welbeck Street, W.), continues to provide daily clinics at 2 p.m. (Saturdays excepted). The in-patient department (Regent's Park) has been reopened to 50 per cent. of its normal peace-time capacity.

Professor Hartmann, the president, has decided that the Academy of Medicine of Paris will meet every fortnight during the war.

The Medical Benevolent Society for the East and North Ridings of the County of York (including the City of York) held its thirty-first annual meeting on September 27 at the rooms of the York Medical Society. The reports of the honorary treasurer and the honorary secretary were adopted, and the grants sanctioned in previous years were again agreed upon, and in one case increased. Votes of thanks were passed to Dr. C. H. Milburn, the retiring president; to Dr. C. Howard Jackman, the retiring honorary secretary; and to Mr. Herbert Locking, F.C.A. New members were elected and the following officers appointed: president, Mr. B. G. Sandys-Belas, Middlesbrough; president-elect, Dr. F. C. Eve, Hull; vice-president, Dr. G. F. Longbottom, Middlesbrough; honorary treasurer, Dr. D. Matheson Mackay, Hull; honorary secretary, Dr. W. W. A. Kelly, York; honorary assistant secretary, Dr. J. D. Burrows, York.

The annual dinner of the West Riding of Yorkshire Edinburgh Graduates Association will not be held this year owing to the war.

The issue for September 23–30 of *Paris Médical,* which is now appearing fortnightly instead of weekly, is devoted to pharmacology, and contains a review of pharmacology in 1939 by Professor M. Tiffeneau.

Poliomyelitis at the present time is on the decline in Sweden: 3,000 cases were notified in 1936, 1,931 in 1937, 1,450 in 1938, and only 69 in the first quarter of 1939, as compared with 155 for the same period of 1938. The disease is more prevalent in the country than in the towns. The age distribution has changed. In 1936 the group most affected was not from 0–5 but from 10–15.

The Bradford Hospital and Convalescent Fund has been compelled to suspend its many winter activities for the time being. Nearly all the usual committee meetings have been postponed, but members are devoting their energies to gaining financial support for the contributory scheme in view of the probable drying up of many sources of ordinary income. The executive committee at its last meeting decided that dependants of contributors who have joined the Royal Navy, the Army, or the R.A.F. should have all the privileges of the scheme without payment of contributions for six months after the contributor's enlistment. After six months those dependants who wish to continue membership may enrol at any depot in the city without observing the usual three months' waiting period.

EPIDEMIOLOGICAL NOTES

Infectious Diseases and Evacuation

Incidence of Infection.—The effect upon the incidence and distribution of the acute infectious diseases of the evacuation of susceptible subjects from densely populated areas to rural districts is becoming more evident as the weeks pass. Little can be said with certainty at this stage on total incidence, as the observed increases in respect of the two principal notifiable diseases—diphtheria and scarlet fever—are no higher than might be expected when schools reopen and the winter months approach. Nor should too much importance be attached to the low incidence of these diseases compared with 1938, since differences as great between consecutive years are by no means uncommon.

The figures for large towns such as London, Manchester, Birmingham, and Liverpool for the week under review show that the principal epidemic diseases have fallen to approximately a quarter of their expected level, presumably on account of the evacuation.

Certain diseases such as enteric and cerebrospinal fevers, in which the attack rate among adults is relatively high, have not undergone any great change; but we may observe that the notifications of enteric for the past four weeks have been 77, 77, 77, and 71; the figures for the corresponding weeks last year were 32, 36, 45, and 27. The rates for puerperal pyrexia in the large towns have also fallen, but not equally, perhaps because of the varying success of particular evacuation schemes.

Susceptibles in Reception Areas.—Mass evacuation has brought in its train problems with which public health authorities in reception areas are only now being faced. Avoidance of spread of infection among the relatively susceptible subjects in rural areas has been sought by providing separate schools or by staggering the hours of school attendance, but there is a limit to the application of these measures, especially with the coming of winter. More success may be anticipated from an intensive immunization campaign, chiefly against diphtheria and to a lesser extent against scarlet fever and whooping-cough. The experience of South Shields may be cited in this connexion. In 1938 there were 598 cases of diphtheria, more than the total for the preceding ten years, with 61 deaths, while in the first nine months of 1939, when immunization was adopted, deaths have fallen to 32 and cases to 409, a large proportion of which were carriers. Among 13,000 children adequately immunized cases have been few and mild and no deaths have been recorded.

Problems of Isolation.—The insufficiency of isolation accommodation in reception areas has afforded opportunities of assessing the merits of home nursing of cases of infectious diseases. The absence of ordinary hygiene and cleanliness in many groups of evacuees, among whom impetigo, scabies, and pediculosis have been rife, has necessitated the provision of additional isolation accommodation in many districts. Local authorities are naturally averse to extensive financial commitments, as the duration and intensity of evacuation remain uncertain.

No. 38

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended September 23, 1939.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (*a*) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1939					1938 (Corresponding Week)

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS.—All communications should be addressed to the Advertisement Manager (office hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are

EDITOR OF THE *BRITISH MEDICAL JOURNAL, Aitiology Westcent, London.*

SECRETARY, *Medisecra Westcent, London.*

The address of the B.M.A. Scottish Office is 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh;* telephone 24361 Edinburgh), and of the Office of the Cumann Dochtúirí na h-Éireann (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin;* telephone 62550 Dublin.)

QUERIES AND ANSWERS

Dermatological Out-patients

Dr. W. GRIFFITH writes in reply to Dr. P. Farrell's question (October 7, p. 752): St. John's Hospital for Diseases of the Skin, 5, Lisle Street, Leicester Square, which had to suspend its services for A.R.P. purposes, has now resumed its normal activities. Out-patients are seen daily at 2 p.m., except Saturdays, and the in-patient department has been reopened.

The Secretary of St. John's Hospital informs us that the out-patient department is open daily from Mondays to Fridays at 1.30 to 3.30 p.m., and that patients who can afford to do so are expected to contribute towards their consultation, treatment, etc., according to their means.

Income Tax

Appointment—Board and Lodging

"C. H." asks what is the basis of liability in the case of an appointment "at so much per year plus emoluments—for example, board or part board with rooms and other perquisites . . . not payable in cash."

⁂ Emoluments not receivable in cash are not liable to assessment unless they are capable of being converted into cash—as, for instance, in the case of a free residence which the employee is permitted to let for a rent. This general principle was laid down many years ago in the leading case of Tennant *v.* Smith. If, however, the terms of the appointment are such that the employee is entitled to a stated salary which is subject to deductions for board, lodging, etc., then the whole salary—and not that amount less the deductions—is assessable to tax.

LETTERS, NOTES, ETC.

Hallucinations

Dr. DORIS ODLUM (London, W.1) writes: The articles on hallucinations by Dr. P. K. McCowan and Dr. Macdonald Critchley in your issue of September 23 recalled two hallucinatory experiences that occurred to me some years ago. I have never met anyone who has had a similar experience, so I assume it to be unusual. At the age of 16 I went to hear Elgar's *Apostles* performed at the Three Choirs Festival at Worcester Cathedral. It was a very exciting experience, and I was in a somewhat "exaltée" emotional state after it. That night I heard the whole oratorio over again in a kind of twilight state which was not like a normal sleep. The reproduction was absolutely accurate—orchestral, solo, and chorus parts were exactly as they were performed the morning previously. About two years later I had a similar experience after my first visit to the opera in Paris to hear *Tannhäuser.* The whole opera passed through my mind exactly as I had heard it that evening. On waking I could not recall anything but one or two of the leading themes. I am fond of music but not especially musical, and usually only recall a few phrases of anything I hear. I should be interested to know if others have experienced or heard of a similar phenomenon.

Evacuated Children

Dr. ARTHUR PAIN (Thorney, Peterborough) writes: I should like to draw your attention to a matter concerning evacuated children. We are going to be paid for the extra work that these children entail. We have over 200 children in our village. At least thirty of them are suffering from impetigo; this means a huge amount of work for our district nurse, and they are seeking her advice on many matters. Our nursing association only just pays its way, and is not in a position to give extra remuneration. I think that some means should be found to give these nurses some additional remuneration for the extra and useful work they are doing.

Dangerous Drugs in the United Kingdom

The annual report to the League of Nations of Great Britain and Northern Ireland for the year 1938 on traffic in opium and other dangerous drugs follows on lines which have become almost stereotyped—no new laws or regulations, no administrative changes, and no difficulties in effectuating the International Conventions of 1912 to 1931; no opium, coca, or Indian hemp are cultivated here, and the manufacture of morphine, heroin, codeine, and dionine is restricted to two firms and that of cocaine to one. The prevalence of addiction in the United Kingdom is repudiated, only 519 persons—273 women and 246 men—are known to the central office as addicts; and morphine is the drug most favoured, that of heroin being a bad second. Of the 519 addicts, 134 are reported to be medical men, five pharmacists, two dentists, and two veterinary surgeons. Prepared opium—that is, for smoking—which is widely used in the Far East and in some of our Colonies, is totally prohibited here. Nearly 12,000 ounces of British-made morphine were exported in 1938, the largest consignments being to New South Wales, Canada, South Africa, and India. There were fifty-nine prosecutions during 1938 resulting in forty convictions: twenty-three were punished by fine, sixteen by imprisonment, and one by penal servitude.

Position of War Blinded

"If war should come there will be many cases of blindness caused by hostile activities, but we have taken all steps possible to deal with the situation as it arises." These words appear in the seventieth annual report of the National Institute for the Blind, 224, Great Portland Street, London, W.1. The position of newly blinded persons—whether members of the fighting services, police, or private individuals—is far different from that which existed in 1914. Since then there has come into being an important scheme of co-ordination which has brought about an advancement probably greater than in any other branch of welfare work. To-day, any person losing his sight becomes straightway the responsibility of his local authority and all interested voluntary agencies, all of which work in close co-operation with the National Institute. Their common aim is the welfare of the sightless; and the Institute has opened its doors widely to all who can usefully co-operate to that end. Its council of eighty members represents the bulk of official and voluntary interest in our blind population. At the time of the outbreak of war this vast co-operative movement was carrying forward its humanitarian work in an ever-widening field, and the work is not to be allowed to slow down. During war the needs of the blind are greater than at any other time.

Economy of Coal Gas

Householders and others faced with new fuel problems will find useful three new publications of the British Commercial Gas Association, 1, Grosvenor Place, S.W.1. One is a "Weekly Record Card" on which can be kept a simple account of the amount of gas used each week, thus checking quarterly consumption. The card is provided with metal tabs for easy hanging up. Another card, "Don't Waste the Gas," gives fuel and food economy hints as well as instructions for meter reading. A pamphlet, "How Gas Rationing affects You" brings the Government rationing regulations down to terms easy to understand.

TREATMENT OF CLOSED FRACTURES OF RADIUS AND ULNA*

BY

St. J. D. BUXTON, M.B., B.S., F.R.C.S.

Senior Orthopaedic Surgeon to King's College Hospital

It seems logical to adopt a standard form of treatment for certain fractures, if such is followed by a normal and lasting function, and is achieved in as short a time as possible. Axis and skeletal traction are considered up to date in the treatment of fractures. In forearm fractures my experience in their use is small and is never likely to be greatly increased, as other methods appear preferable. It is my intention to lay stress on the appreciation of the anatomical relationship of the radius and ulna at the superior and inferior radio-ulnar joints when fractures of the forearm are treated.

In the review of nearly 400 cases of forearm fractures it has been interesting to study the length of time each case has been under treatment. To make this possible the cases reported are only those treated from start to finish in one institution. Cases treated in nursing homes and other hospitals and those referred after some treatment—a considerable number—are excluded. This method of investigation has advantages in that the work has been in one clinic and the immediate setting has been carried out, in the greater number of cases during a five-year period, by casualty officers and orthopaedic house-surgeons, who show the utmost keenness and are severely critical of the success of their work, but are in no sense of the word experienced until it is time for them to pass to other appointments. Hence methods are advocated which are considered the simplest and seldom necessitate the admission of the patient to hospital: further manipulative or operative methods are employed only when they fail. Of 374 fractures it is found that twenty-eight were treated by open operation (7.4 per cent.). This low figure is accounted for by the large number of greenstick fractures in the series, for 75 per cent. of the fractures occurred in patients under the age of 20.

It is obvious that hospitals in industrial areas have in their clinics a far greater proportion of closed forearm fractures in adults than occur in this series, and my own experience is enlarged by accidents seen elsewhere. However, the detail of the treatment of the common injury, simple as it may appear, is worthy of consideration.

Group I—Bamboo and Greenstick Fractures with Little or No Displacement

After *x*-ray examination a plaster is applied, usually no anaesthetic being required. Records show that some of the slight injuries were treated on Carr's splint. A child is safer at school with the plaster on, and seldom does a parent meddle with it. The type of plaster employed is standardized for all the fractures under discussion.

	No. of Cases	Upper Third	Middle Third	Lower Third	Average Time Under All Treatment (Weeks)	Longest Time Any One Case Under Treatment (Weeks)
Radius and ulna	31	0	9	22	6.2	12
Radius ..	58	0	5	53	5.8	9
Ulna.. ...	4	1	2	1	6.7	10
Group as a whole	93	1	16	76	6.2	12

METHOD OF APPLYING PLASTER-OF-PARIS BANDAGE

The elbow is bent to a right-angle, and the forearm supinated and wrist slightly dorsiflexed. A thin slab of plaster is applied to the back of the arm and extensor surface of the forearm, extending from the lower border of the axilla to the metacarpal necks. This fits accurately on to the skin, and by two lateral cuts is made to fold round the elbow, coming forwards just over the epicondyles. It should cover slightly more than the posterior half of the skin area of the limb. A piece of wool is placed in front of the elbow. A flannel or plaster wool bandage is applied round hand, forearm, and arm to secure the plaster to the skin and to act as padding for the flexor surface of the forearm and antecubital fossa. A plaster bandage is wound round the limb from metacarpal necks to lower axillary border. This is never pulled tight, but folded to and fro and moulded in. The most distal turn should be round the neck and head of the metacarpal of the index finger and not in the apex of the web between thumb and index finger. A second bandage similarly applied may be required. During the moulding process an attempt should be made to produce a slight furrow along the front and back of the forearm in the line of the space between radius and ulna, but the inclusion of a piece of wood in the plaster to serve this purpose is unnecessary.

When the plaster extends only to "just above the elbow" some movement will take place at that joint, so that the plaster will cut in at the back of the arm and in front at the fold of the joint.

The patient is instructed to move the shoulder, fingers, and thumb straight away, and in some cases is advised to attend the massage department for assistance. Swelling of the hand may result from the injury itself or a plaster splint applied too tightly or incorrectly. Flexion contracture of the fingers may be due to haemorrhage in the forearm muscles, too tight a plaster, or the beginning of Volkmann's ischaemic contracture.

---

* Read in the Section of Orthopaedics and Fractures at the Annual Meeting of the British Medical Association, Aberdeen, 1939.

Group II—Greenstick Fractures with Angulation of One or Both Bones, which were Treated by Closed Methods

	No. of Cases	Upper Third	Middle Third	Lower Third	Average Time Under All Treatment (Weeks)	Longest Time Any One Case Under Treatment (Weeks)
Radius and ulna	114	11	64	39	8.6	16
Radius ..	44	1	11	32	7	11
Ulna.. ..	6	1	3	2	7.7	11
Group as a whole	164	13	78	73	7.8	16

When any angulation is present the child is anaesthetized and the fracture is completed, so that the forearm bones can be fixed in plaster in anatomical alignment. If this is not carried out deformity will follow which may or may not straighten out subsequently. If one bone only is affected the supination-pronation range of movement may be limited for some time and the other bone may bow as it grows. The completion of the fracture is simple if carried out over a rubber-padded wedge of wood. At first there is a fear of doing damage or of causing displacement, but it is quickly overcome. When one bone is angled in the upper third and the other two or three inches lower down, the forearm should be placed obliquely over the wedge. Reference will be made to re-fractures in children later; because of these, six weeks' complete fixation and a week in the posterior half of the plaster is considered necessary.

Group III—Fractures Other than Greenstick, which Required no Reduction, or in which Reduction was Contraindicated

	No. of Cases	Upper Third	Middle Third	Lower Third	Average Time Under all Treatment (Weeks)	Longest Time Any One Case Under Treatment (Weeks)
Radius and ulna	5	0	3	2	9.5	20
Radius ..	10	0	3	7	8.4	19
Ulna.. ..	14	2	6	6	14.8	20
Group as a whole	29	2	12	15	10.9	20

The injuries recorded in this group have been treated on similar lines. The patient usually reaches hospital wearing a first-aid appliance with the forearm pronated. Manipulation into full supination is painful, so that an anaesthetic is necessary for the application of the plaster. The fractures of interest in Group III are those of the ulna alone. If there is a crack only, or a fracture with one or more loose fragments lying close to the bone, union will not be delayed. Both the fractures of the upper third of the bone took longer than the average time to unite, and one took twenty weeks. The average is nearly double that recorded for the radial fractures, but possibly extra care was employed. In this series there was no case of non-union in the lower third, the recognized danger area.

There is no doubt that the basis of Baldwin's operation is well founded, as periodically patients seek treatment for non-union of the ulna three inches or so above the wrist when fixation has been brief. When further fixation or physiotherapy fails to produce union a bone graft is advisable. Consolidation of graft and bone is more likely to occur if a tibial graft is used in preference to a sliding graft from the ulna.

Group IV—Fractures Other than Greenstick with Overlap or Angulation, which were Treated by Closed Reduction

	Total	Upper Third	Middle Third	Lower Third	Average Time Under All Treatment (Weeks)	Longest Time Any One Case Under Treatment (Weeks)
Radius and ulna	39	2	17	20	9.3	26
Radius ..	14	3	2	9	9.3	24
Ulna.. ..	7*	2	2	3	9.4	13
Group as a whole	60	7	21	32	9.3	26

* Includes two cases of fracture of the upper third of the ulna with dislocation of the upper end of the radius.

Treatment of fractures in this group is one of the most difficult problems in fracture surgery. Success in alignment by closed reduction is economical in the patient's time and saves pain and further operative treatment.

Radius and Ulna.—When there is *angulation* this is corrected and a plaster is applied under an anaesthetic. *When there is overlap* the patient is anaesthetized and traction and countertraction applied. Manipulation will frequently succeed in reducing the transverse and, less often, the oblique fractures. If neither bone hitches the fractured ends are turned backwards towards the extensor surface of the forearm and an attempt made to hitch them. This method is easily understood by those who employ it in open reductions. Should this fail a method worthy of trial is to manipulate the radius only and, if this hitches, employ the radius as a lever and pull out to full length the fragments of the ulna. The reverse of this is less easy.

(i) If alignment and end-to-end apposition are achieved—that is, "both bones hitched"—plaster is applied in the manner described. For its application with the patient recumbent the arm is abducted to a right-angle, the elbow flexed to a right-angle, and the fingers, pointing to the ceiling, held by an assistant. It is most important to mould in the interosseous space to prevent it "being crowded," as there is a great tendency for the upper radial fragment to tilt towards the ulna.

(ii) If neither bone can be hitched the decision has to be made as to whether to employ fixation with the bones in the position of overlap or to proceed to another method of reduction. It is universally accepted that unreduced fractures of the lower third of both bones, at the same level, in children are followed by full function and a perfect radiographic appearance after a few years. This may also apply to fractures of the upper third, but the prognosis is less certain. In adults overlap of both bones should be corrected.

(iii) If one bone is hitched and the other not, the decision whether full function will be obtained is usually difficult. In children, when the radius is hitched and not the ulna, plaster is applied; but when the ulna is hitched further treatment is advised. In adults, risk as to ultimate function is taken if alignment is not restored. Should it be found that good alignment with ample separation of the radius and ulna cannot be obtained with the forearm fully supinated, but is possible, say, in mid-position, the limb should be put in plaster in this position. Similarly, full wrist dorsiflexion or slight palmar flexion—although undesirable on general principles—may enable the surgeon to place the bones in better alignment.

The treatment advocated when manipulation has failed is considered subsequently, when operations on forearm bones are discussed.

The value of physiotherapy in these cases of imperfect reduction is worthy of consideration. The most valuable form is what may be termed "preventive." If the patient moves the fingers and thumb from the day of the fracture, which is always possible in closed fractures, there should be no stiffness of finger-joints, and the wrist and elbow will regain their movements if their fixation has been in the correct position. As pronation is a movement of necessity, the patient will regain this if the mechanical relations of bones and radio-ulnar joints allow it and the muscles and their nerve supply are intact. The muscles will be assisted by physiotherapeutic measures when fixation can be released.

RADIUS

As overlap of the radius may be associated with a complete separation of the lower epiphysis of the ulna, or in adults with subluxation or dislocation of the inferior radio-ulnar joint, it is important that the skiagram should include the wrist-joint. Theoretically, it should be easier to reduce by manipulation a fracture of the radius alone than one of both bones, as the ulna can be used as a lever. This is seldom the case, as fractures of the radial shaft are usually oblique and will not hitch. If manipulation fails to correct an overlap in the distal half of the radius, further measures should be adopted to correct this in an adult; but it is not always necessary in a child. If the inferior radio-ulnar joint is not in anatomical alignment open reduction is advisable (see below).

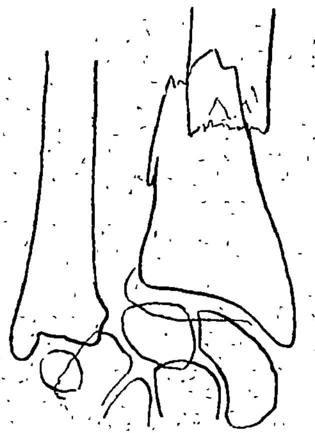

FIG. 1.—Sketch to illustrate fracture of radius with overlap and dislocation of inferior radio-ulnar joint.

ULNA

No discussion on fractures of the ulna alone is complete unless adequate thought is given to the "fracture of the ulna in its upper third associated with an anterior dislocation of the upper end of the radius." The anatomy of the fracture is an angulation or overlap of the ulna, with displacement of the head of the radius above the capitellum, the orbicular ligament being torn. The radial head may be within or have penetrated the anterior ligament of the elbow-joint. There is shortening of the length of the forearm. The injury is most common in childhood, when the ulna is usually broken in the upper third; after the age of 15 the ulna tends to be broken nearer the centre of the shaft. The injury is not to be confused with (*a*) oblique fracture of the olecranon with forward dislocation of the radius and ulna, with intact orbicular ligament usually occurring in the early "teens"; nor with (*b*) fracture of the upper third of the ulna with fracture of the radial neck in adults.

A correct diagnosis is essential for the treatment. Error may occur owing to the skiagram not including the elbow-joint, so that there is lack of appreciation of the dual injury. Early and correct treatment should produce a normal elbow. Unsuccessful treatment or delayed treatment may be followed by limitation of movement and weakness, particularly if a false joint is formed at the site of ulnar fracture. All the cases that have been treated by manipulation and plaster, or by operation, within a few days have full movement and no disability, whereas all cases operated on after delay have disability, including the case of a boy aged 4. The immediate treatment consists of reduction and fixation.

Reduction.—Unless the head of the radius has passed through the anterior part of the capsule, which is probably rare, the reduction of this dislocation causes no difficulty. As length is given to the forearm by such a manipulation, the ulna tends to come into alignment. However, this is not sufficient, for the length of the forearm should be maintained by the ulna, so that there is joint space between the head of the radius and the capitellum. If the surgeon relies on the length of the forearm being maintained by the radius, the radial head is likely to be pressed against the capitellum. In that position redislocation is liable to occur, or if it does not erosion of articular cartilage and subsequent traumatic arthritis will follow. Hence the alignment of the ulna is the primary consideration. When the fracture is transverse or oblique with a notch, it should be possible to manipulate the bone until it is hitched and full length obtained. Probably during the manipulation the upper end of the radius has slipped back into place. If the ulnar reduction is difficult traction and counter-traction with manipulation can be tried, or the manipulation can be repeated after reduction of the head of the radius.

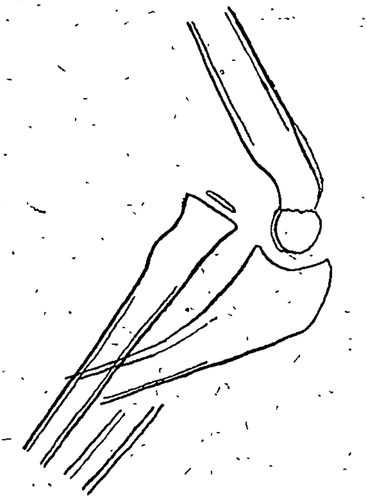

FIG. 2.—Sketch of typical fracture of upper third of ulna with forward dislocation of upper end of radius.

Fixation.—As soon as the surgeon feels confident that he has achieved the reduction, a plaster is applied as for a fracture of the forearm. At the same time traction and countertraction should be applied by a band round the arm tied to a hook or held by an assistant, and by traction on the fingers. Moulding to keep the upper half of the radius back is as important as that to maintain the ulnar alignment. This plaster is removed in six weeks, and the posterior half worn for another two weeks.

There is likely to be criticism of this position of the arm, as acute flexion is reputed to be the position of choice after setting this fracture-dislocation. But it is recognized by advocates of this position that redislocation may occur. In acute flexion no attempt is made to keep a joint space, and the cup on the head of the radius may not remain in correct relation to the capitellum. Further, the alignment of the ulna is far more difficult to control in this position than when the elbow is at a right-angle. Although some orthopaedic surgeons may favour the acute-flexion position and take exception to the position advocated, probably all agree that the best functional end-results are to be expected if the ulna has been allowed to heal with no deformity or shortening.

INDICATIONS FOR OPEN OPERATION

On the Ulna.—(*a*) Failure to reduce the overlap of the ulna. (*b*) Rare cases when the upper end of the lower ulnar fragment has penetrated the skin. An open reduction is likely to enable the surgeon to hitch the ulna and give it full length, and internal fixation is not required unless there is a constant tendency to angulation. (*c*) In late cases with angulation of the ulna or non-union of the fracture.

On the Radius.—(*a*) When reduction is not achieved by manipulation the outer side of the elbow-joint should be explored and the entanglement of the head in the soft structures relieved. (*b*) When redislocation of the radius occurs: it is contended that this is not an indication for operation on the radius, as it can be controlled by proper reduction of the ulna and moulding of the plaster. (*c*) In late cases of unreduced dislocation the question may arise whether a greater range of movement will occur if open reduction is employed. It is considered that an open reduction of the dislocation and of the fracture by separate incisions is indicated if the patient is seen during the second to sixth week or so.

After a long interval in an unreduced case it may be tempting to remove the head and neck of the radius, but little is to be gained by this, and the arm is likely to be weaker.

On the Orbicular Ligament.—Fascial grafts to repair or replace the orbicular ligament can be employed. If an open reduction of the dislocation is indicated a stitch without a graft will assist in the healing. When a case is operated on a few weeks after the injury an attempt to make a new ligament is desirable. In the late unreduced cases such a repair is not likely to be followed by good function. The fixation of the fascial graft to the ulna is difficult.

OPERATIVE TREATMENT OF FRACTURES OF RADIUS AND ULNA

If manipulation fails to correct displacement of the fracture the surgeon has to decide on the next procedure. This decision should be made immediately, because an operation will be more difficult after a few weeks, and its result is likely to be less effective than if it is undertaken as soon as the skin is adequately prepared. It has been stated already that failure to correct overlap of forearm bones in children does not necessarily indicate that further intervention is advisable. The procedures possible are:

Closed Reduction by Mechanical Methods.—(*a*) By axis or skeletal traction: neither of these has appealed to me in treating the fractures under discussion, and my experience is limited. (*b*) Manual traction assisted by manipulation of Steinmann's pins inserted into one or both fragments.

Open Reduction.—When carried out within a few days of the injury open reduction makes it possible to restore anatomical alignment with little trauma to the tissues. The pain is slight after two days, and function is restored in a reasonable time. Provided adequate skin preparation is undertaken and the operation is done under such conditions as are suitable for any bone surgery, the risks of complications are minimal.

Group V—Fractures Other than Those Shown in Groups I-IV which were Treated by Open Operation owing to Overlap, and Failure of Closed Reduction

	No. of Cases	Open Reduction	Plating One or Both Bones	Bone Graft	Average Time Under All Treatment (Weeks)	Longest Time Any One Case Under Treatment (Weeks)
Radius and ulna	22	16	5	1	20.2*	112
Radius ..	4	0	4			
Radius lower third with separated ulnar epiphysis ..	1	1				12
Ulna upper third with dislocation upper end radius ..	1	1				12
Group as a whole	28	18	9	1		

* If 2 cases under treatment for 112 and 52 weeks are excluded, the average length of time under treatment is 15 weeks.

OPERATION

This is as follows. (*a*) Application of pneumatic tourniquet after exsanguination of the limb. (*b*) Exposure of the fracture and a length of the shaft above and below this. (*c*) Incision and raising up of the periosteum and attached muscles in the axis of the limb. (*d*) Elevation of each end of the fracture by grasping the shaft an inch from the fracture with bone-holding forceps which will fit the radius or ulna. (*e*) Removal of clot and other intervening substance. (*f*) Realignment and hitching of the bones by grasping each fragment; this is possible by traction, or angulation into the wound, hitching, and straightening. It may be necessary to carry out this on each bone. It is my routine to restore the radius first. If the ulna has hitched as the length of the forearm is re-established, the bone is not exposed. If the ulna has not hitched the radial wound is packed and the ulna realigned through a second incision. The ulnar fracture will generally dovetail in and fit snugly. This wound is closed and the radius is then realigned.

(*g*) *Fixation.*—(i) In most cases requiring operation the fracture of the radius and ulna is oblique, but there are notches at the fracture, which can be fitted in. So the operation is limited to an open reduction. If the bone fits snugly and does not bow, the periosteum and overlying muscles are stitched, the wound closed, and plaster applied. A small dressing is used and a plaster slab applied to skin and dressing on the extensor surface of the limb. More padding is applied before circular turns are made. (ii) Internal fixation is advisable in all cases of fracture of the radius in the upper third owing to the tendency for the upper fragment to swing inwards, and in every case in which there is doubt as to whether the radius will stay in correct alignment. A thin plate with two screws in each end is used. Obviously the risk of inserting a plate by Lane's technique is small, and nothing can be more disheartening than the occurrence of angulation or slipping of the bones during the closure of the wound or application of the plaster-of-Paris after an "open reduction" without fixation. Plating of the ulna is seldom necessary. A bone graft may be employed if a long loose fragment makes the application of a plate to the two ends of the shaft difficult. Cases of non-union of bone after plating radius and ulna are known to us. It is usually possible to obtain the history and serial skiagrams. This serious complication appears to be due to fixation of the plate to the shaft although the fractured ends are not in apposition, to loosely fitting screws, to the introduction of sepsis, or to splinting of an inadequate type or for too short a period. In some cases more than one of these factors has been present.

All the cases reported in Group V are known to have full function. The case under treatment for 112 weeks is interesting in showing difficulties which may be encountered.

A girl aged 8 had a transverse fracture at the junction of the middle and lower thirds of the radius and ulna, with overlap of the bones. At the time of the primary reduction, which was satisfactory, it was noted that she had blue sclerotics. She had not broken any other bones. Just before she was due for discharge she fell down and re-fractured the limb, producing a similar fracture. It was again reduced satisfactorily. Shortly after the child left hospital the mother thought the plaster was dirty, so she immersed the whole limb in water. When this plaster was removed the arm was tense and the child developed the signs of an ischaemic paralysis. She was under treatment for many months for this, and union of the bone was delayed. While still under treatment she broke it again, but the setting was not satisfactory and an open reduction was carried out. That was in 1936, and the child now has a normal arm.

The patient under treatment for one year was a man of 36 who had the radius and ulna plated. The records suggest that he wished to attend hospital until litigation was settled. Apart from these two cases the average period of treatment is 50 per cent. longer than when treatment is by closed reduction.

Complications

Swelling of the forearm is a frequent sequel to reduction and application of plaster-of-Paris. This should be treated by incising the plaster up the middle of the front of the forearm, and not by enlarging the opening for the fingers and thumb. If the patient is not relieved the incision should extend the whole length of the plaster. The plaster should be prised open, and later can be fixed together by elastoplast. *Re-fracture* occurred in this series in ten children; of these, three had re-fractures twice and one three times. It is difficult to determine how many of these sustained a subsequent injury sufficient to break a normal bone. When some years ago it was first noticed that re-fractures were occurring, the length of fixation was increased; but study of the records does not suggest that this eliminated the complication, to which attention was drawn by me (Buxton, 1926). *Volkmann's ischaemic contracture* (Garber, 1939) occurs in a small number of cases treated either in plaster casts or splints. It may be accompanied by median nerve paralysis. Its recognition should be followed by removal of splinting and elevation of the limb. If pain persists and voluntary movement is still greatly restricted, operation is indicated within a few hours. *Median nerve paralysis* without contracture was seen in one case in the series. Delayed operation restored function. Ulnar nerve injury has not been observed. *Synostosis* of radius and ulna is recorded as a not uncommon sequel to infected fractures of radius and ulna, but must be rare in closed fractures. *Decalcification* of the forearm bones and carpus may follow closed fractures in children and adults, but is less common than around the ankle. It appears that imperfectly reduced fractures are more liable to this complication than those which have been perfectly aligned.

Conclusion

In the treatment of forearm fractures two principles must form the basis of treatment: the correction of displacement of the bones and the fixation of the limb for a sufficient length of time to prevent the risk of displacement. The patient has seldom to be in bed; for even after operation he can be up in a few days. The shoulder and fingers should be moved by the patient himself from the beginning of the treatment. The superior and inferior radio-ulnar joint must be in perfect anatomical position after setting a forearm fracture.

Summary

The progress of nearly 400 fractures treated in one hospital has been studied. These are considered in five groups.

Stress is laid on recognition and treatment of dislocation or subluxation of the superior or inferior radio-ulnar joint with fracture of a single forearm bone (fracture of upper half of ulna and forward dislocation of upper end of radius, and fracture of lower third of radius with dislocation of inferior radio-ulnar joint).

Volkmann's ischaemic contracture is recorded.

CLINICAL SIGNIFICANCE OF TUBERCLE BACILLI IN THE URINE

BY

C. E. DUKES, M.Sc., M.D., D.P.H.

Pathologist to St. Peter's Hospital for Stone and St. Mark's Hospital, London

The term "urinary tuberculosis" is used to describe a clinical condition characterized by tuberculous lesions in the urinary tract, by the presence of urinary symptoms, and by the excretion of pus and tubercle bacilli in the urine. The term "tuberculous bacilluria" is employed to cover an occult or subclinical tuberculous infection associated with the excretion of tubercle bacilli in the urine but unaccompanied by any urinary symptoms. Tubercle bacilli are to be found in the urine in both these conditions, but it is important to decide whether the case is one of established urinary tuberculosis or of simple bacilluria. The object of this paper is to compare the results of urine tests in these two conditions.

Tuberculous Bacilluria

Tuberculous lesions of the urinary organs, whatever be their location, are almost invariably the consequence of a blood-stream infection from an active tuberculous lesion in some other organ in the body. All the evidence goes to show that the kidney is the first part of the urinary tract to be affected and that the renal lesion is at first bilateral. Tubercle bacilli brought to the kidney by the blood stream give rise to minor tuberculous lesions unaccompanied by signs or symptoms. Most of these are undetected and heal spontaneously without causing any discoverable injury. So long as these minor lesions persist, tubercle bacilli may be excreted in the urine in small numbers. Conversely, whenever tubercle bacilli are found in the urine it may be assumed that pathological lesions exist in the kidney, though a particularly thorough examination may be necessary to discover them. A perfectly healthy kidney cannot excrete tubercle bacilli.

This type of occult or subclinical tuberculous infection of the kidney, accompanied by tuberculous bacilluria, may occur in any form of tuberculosis, but it is specially likely to be found in forms of tuberculosis spread by the blood stream, such as disease of bones and joints. Harris (1930) proved the existence of tuberculous bacilluria in sixteen out of forty-three adults and nine out of sixty-seven children with tuberculous bone lesions. Band (1935) also found tubercle bacilli in the urine of twenty-five out of 174 patients with extra-urinary tuberculosis. He watched these patients for several years, but only two subsequently developed renal tuberculosis. Tuberculous bacilluria is not so common in pulmonary tuberculosis, and Menton (1932) found only one case in seventy-six patients examined. However, the proportion of positive findings must depend on the frequency with which tests are carried out. Mack (1937) found fifteen cases of tuberculous bacilluria in twenty cases of extra-urinary tuberculosis, but some of his cases were examined several times. One patient was examined on fourteen occasions, but only four tests were positive.

The suspicion may arise that a tuberculous bacilluria is simply the first sign of clinical renal tuberculosis, which may manifest itself with the usual signs and symptoms at a later date. This is not necessarily the case. Many patients suffering from tuberculous lesions in other organs of the body than the urinary tract, but exhibiting tuberculous bacilluria, have been kept under observation for several years, yet no urinary symptoms have developed. In fact, further tests have shown that the kidneys have ceased to excrete tubercle bacilli, and it may be assumed that the minor lesions in the kidney have healed. We are now in a position to group together the features which characterize the excretion of tubercle bacilli in tuberculous bacilluria. They are as follows:

(1) Only a few tubercle bacilli are excreted in the urine, and it is very rare for them to be discovered in stained films of the centrifuged deposit. Guinea-pig inoculation is nearly always necessary for the demonstration of tuberculous bacilluria. (2) The excretion of tubercle bacilli is intermittent, so that the test may be positive on one occasion and negative on another. (3) The urine is clear in appearance and does not as a rule contain pus or blood, but at the time when tubercle bacilli are being excreted microscopical examination will reveal an excess of leucocytes in the urine. (4) In cases of tuberculous bacilluria the excretion of tubercle bacilli may cease when the patient's general health improves.

Urinary Tuberculosis

As already stated, there is abundant evidence that the minor tuberculous lesions of the kidney responsible for tuberculous bacilluria may heal spontaneously; on the other hand, a small proportion progress and give rise to clinical urinary tuberculosis. No hard-and-fast line can be drawn between tuberculous bacilluria and clinical urinary tuberculosis, but in general it may be said that clinical urinary tuberculosis is accompanied by symptoms, by constant abnormalities in the urine and pathological changes in the kidney, demonstrable by radiology and by renal function tests. Since in most cases the patient only comes for medical examination when urinary symptoms have developed it follows that tuberculous disease of the urinary organs is rarely discovered in the preclinical phase. Now, the symptoms of urinary tuberculosis are not directly due to disease of the kidney but are caused chiefly by the passage down the ureter of irritating material and by the extension of the disease to the ureter and bladder. In fact, most cases of urinary tuberculosis are not diagnosed until the tuberculous lesion in the kidney has broken down and discharged its contents into the renal pelvis and infected the ureter and bladder. The disease is now at such an advanced stage that it may require to be treated by nephrectomy if only one kidney is affected.

Surgeons have often declared that nephrectomy is the only treatment for unilateral tuberculous disease of the kidney, because the disease cannot heal by natural means. This statement should be qualified by saying that natural cure is unlikely in any case of urinary tuberculosis discovered by a surgeon, for the simple reason that the surgeon has discovered it too late. In the earlier pre-clinical stage the disease might well have been arrested and cured by medical treatment. Up to the present the only patients who have had the good luck to have their renal tuberculosis discovered in the pre-clinical or occult stage have been those who happened to be selected for inclusion in a research or who enjoyed the services of an exceptionally thorough clinical pathologist. A much larger number of cases might be discovered and be given timely medical treatment if urine tests were carried out as a routine in extrarenal tuberculosis, especially in disease of bones and joints which are obviously haematogenous in origin. Regular examination of the urine with inoculation into guinea-pigs might thus reveal cases of tuberculous bacilluria in the pre-clinical stage. Surely it is as important to watch over incipient tuberculosis of the urinary organs as it is to carry out repeated examination of the chest or of the rate of blood sedimentation.

Comparison of Urinary Conditions

We may now compare the condition of the urine in clinical urinary tuberculosis with the state of affairs in tuberculous bacilluria. The chief points of distinction are as follows:

1. In clinical urinary tuberculosis the urine contains large numbers of tubercle bacilli, and they can generally be found in stained films of the centrifuged deposit. Cultures and guinea-pig tests are rarely necessary for the diagnosis of clinical urinary tuberculosis. It is better to repeat the microscopical examination two or three times and to make films from the deposit of a twenty-four-hour specimen of urine. When these tests have been negative, and I have proceeded to cultures and guinea-pig tests in order to allay the importunity of a surgeon, I have nearly always found the cultures and guinea-pig tests also to be negative. It often happens that something else is discovered during the six to eight weeks required for animal inoculation tests, and by the time the little guinea-pig has ploughed its lonely furrow the interest in his behaviour has considerably declined.

2. The excretion of tubercle bacilli is constant, and acid-fast bacilli can be found in films almost each time the urine is examined. I have proved this by repeating urine tests frequently, and in most cases of urinary tuberculosis it has been possible to find tubercle bacilli each day the urine was examined. In six cases of urinary tuberculosis in which acid-fast bacilli were relatively scanty I collected each specimen of urine the patient passed over a period of twenty-four hours (usually fifteen to twenty samples) and examined each one with the object of finding out at what time of the day or night tubercle bacilli were excreted in largest numbers. As a rule tubercle bacilli were most easily found in the urine passed first thing in the morning. This was not due to any influence of the hour, but simply to the fact that these samples were the most concentrated and contained the largest quantity of pus.

3. In urinary tuberculosis the urine always contains a few pus cells, and often the pyuria is sufficient to cause a definite

turbidity. I have never found tubercle bacilli in films of urine which did not contain a very few pus cells or a few red blood corpuscles. If a very dilute and watery urine is sent for examination and no pus or blood or bacteria are found in the films the best plan is to arrange to examine a more concentrated specimen or the deposit from a twenty-four-hour sample.

4. In urinary tuberculosis the excretion of tubercle bacilli will continue as long as the tuberculous lesion can discharge freely into the urinary tract. Whenever tubercle bacilli are found easily in films from the centrifuged deposit of the urine one can be sure that there is an open tuberculous lesion of the urinary tract, and if acid-fast bacteria are found in urine collected from one kidney it is certain that there is a tuberculous lesion of the kidney discharging into the renal pelvis. I reached this conclusion as the result of dissection of sixty tuberculous kidneys removed by nephrectomy before I knew of the work of Medlar (1932), Lieberthal and von Huth (1932), and Kjaer (1937). In each of these sixty cases I had examined the urine before operation, and in some had found tubercle bacilli in films, whereas in others the diagnosis had been based on guinea-pig tests, on cultures, or by other means. Whenever tubercle bacilli had been found in films the subsequent dissection of the kidney revealed an open tuberculous lesion. The smallest focus was a small tuberculous ulcer situated on the apex of a renal papilla. Next in size were small caseating lesions communicating with one of the calices. Tubercle bacilli were present in largest numbers in the ulcerating type of tuberculous lesion with extensive cavities. The films were generally negative in closed tuberculous lesions associated with calcification. In one case with double renal pelvis and double ureter I found pus and tubercle bacilli in the urine from the upper ureter, but the urine from the lower ureter contained no pus, and no tubercle bacilli were seen in films. On examining the kidney after it had been removed by nephrectomy I found an open tuberculous cavity communicating with the upper renal pelvis, whereas the tuberculous lesion of the lower pole was "closed" and had no direct communication with the lower renal pelvis.

Summary

Tuberculous bacilluria is the result of an occult or subclinical tuberculous infection of the kidney, and may occur in many different forms of extrarenal tuberculosis, especially in disease of bones and joints. Tubercle bacilli are present in the urine in small numbers only and are rarely found by microscopical examination. Guinea-pig tests are necessary to demonstrate tuberculous bacilluria. The excretion of tubercle bacilli is intermittent. The urine is generally clear in appearance, though containing an excess of leucocytes. The excretion of tubercle bacilli may cease when the patient's general health improves.

In clinical urinary tuberculosis the urine contains large numbers of pus cells, and these can generally be found in stained films. Guinea-pig tests and cultures are rarely necessary. The excretion of tubercle bacilli is constant, and will continue as long as an open tuberculous lesion can discharge freely into the urinary tract. In clinical urinary tuberculosis the urine always contains a few pus cells, and often the pyuria is sufficient to cause a definite turbidity. These points enable a distinction to be made between results of laboratory tests in tuberculous bacilluria and in clinical urinary tuberculosis.

A PSYCHOLOGICAL ASPECT OF THE REARMAMENT PROGRAMME

BY

S. BARTON HALL, M.D., D.P.M.

Honorary Psychiatrist, Liverpool Royal Infirmary

It is forty-six years since Sir William Mather, at the Salford Engineering Works, found that reduction of weekly working hours from fifty-three to forty-eight resulted in an actual increase in total output. During the present century, and before the war of 1914–18, there gradually accumulated evidence which further illustrated the positive relation which modification of working week bore to increase of output. These findings were confirmed by the Health of Munition Workers Committee (1917 and 1918). Knight, writing in 1928, summarized his comments as follows:

> (i) Every reduction in the working day leads to a decrease in accidents, spoiled work, sickness, and absence. (ii) The reduction of working hours from twelve to ten leads to an increase in hourly and daily output. (iii) The reduction of working hours from ten to eight leads to a further increase in hourly and daily output, except in operations whose speed depends mainly on the speed of machinery. (iv) The reduction of working hours below eight, though increasing hourly output, does not usually lead to an increase in daily output.

To some engaged in medical, and particularly in psychiatric, practice it is becoming apparent that these lessons, even if they have been learnt, are not being adequately applied at the present time, and the aim of this communication is to enlist the help of the profession in drawing attention to the problem before its effects begin to make themselves felt not only upon the health of individuals concerned but upon the vigour with which the nation can continue to prosecute its cause.

Statement of the Problem

Among cases of psychoneurosis investigated at a psychiatric out-patient clinic, and in which occupational factors are prominent, there has lately come to be included a type of breakdown that can be ascribed to a situation having fairly well-defined features. The clinical characteristics, though of less striking interest than the features of the situation from which they derive, have exhaustion in some form as their common basis, and they may be grouped as follows:

(*a*) Relative failure referred to cognitive function in its finer aspects, such as attention and its associated processes of application, concentration, recent memory, maintenance of train of thought, and ability for expression. (*b*) Diminution of instinctive "drives" as displayed by some failure of emotional life, volitional and conative trends such as ability for interest, affection, capacity for "looking forward," general resilience and spontaneity—the "personality" of the patient in the sense used by Mayer-Gross (1938).

The features of the underlying situation found to be common to all cases were: (i) Skilled nature of occupation. (ii) High degree of individual, or collective (foreman), responsibility. (iii) Atmosphere of "rush" and pressure reinforced by knowledge that work was connected directly or indirectly with the nation's emergency and rearmament programme. (iv) Continuous "overtime" work, with resulting extension of working week considerably beyond normal working conditions. (v) Relatively high wages, and increased opportunity for wage-earning partly contributed to by Item iv.

Illustrative Case Material

A. B., aged 29, worked as a fitter in an arms factory. From the age of 14 to 28 he had worked in a similar capacity making machinery used in biscuit manufacture ("that suited me fine—moving about on all different types of work"). Before his breakdown he was working seven days to the week, his hours being distributed in the following way: Monday to Friday inclusive, 8 a.m. to 10 p.m. (with breaks totalling one and a half hours); Saturday and Sunday, 8 a.m. to 5 p.m. (break one hour) On alternate Sundays he was allowed off. His total working week was seventy and a half to seventy-eight and a half hours. From time to time he had the opportunity of working occasional "bursts" from 9 a.m. Monday to 5.30 p.m. Tuesday, continuously save for the usual breaks (one hour dinner, half an hour tea), together with a rest period of three hours for sleep. His weekly earnings averaged £7 15s. It was during one of the "thirty-two-hour bursts" that the patient "felt something snap" inside his head—the start of his breakdown. He complained of inability to shift his mind from one thing to another, mental depression, and pains in the limbs. He stated that "crowds overface me." He spontaneously observed that "chronic monotony set in with me; I'd never been used to being tied in the one place." He volunteered the view that his breakdown was attributable to overwork.

C. D., aged 57, was a foreman electrician to a large shipbuilding yard, where he had worked as improver, journeyman, charge-hand, and foreman for forty years. During the long years of slump and depression in trade, in which the shipbuilding industry was seriously involved, the patient had no difficulty in shouldering the responsibility, that of chief in his own department, for the whole yard. With the advent of rearmament, however, and the securing of large Government contracts the position changed very materially, and the firm were constrained to reopen a yard that had lain idle. Five weeks before being referred for psychiatric investigation the patient had had what he described as "an improvement" at work—he had been made foreman over the two yards—"and they're mad busy." He was delighted at first, had welcomed his promotion with enthusiasm; then, ten days before being seen, "something seemed to strike me in the back of the head." He complained of inability to concentrate, weakness in the legs, worry about his work, pain at the back of the head, and the feeling that he was "worn out." He expressed the view that if he had his old job back (that is, responsibility for one yard only) his difficulties would disappear.

E. F., aged 27, was a tool-setter in an aircraft factory, where he first began work in April, 1938. For three to four months before being referred for psychiatric investigation he had been working seven days a week and on continuous overtime, his hours being distributed as follows: Monday to Thursday inclusive, 8 a.m. to 8 p.m. (breaks totalling one and a half hours); Friday, 8 a.m. to 6 p.m. (break, one hour); Saturday and Sunday, 8 a.m. to 5 p.m. (break, one hour). His weekly earnings amounted to over £8. He complained of mental exhaustion, mental depression, physical feelings of tiredness, and lack of natural inclinations and appetites.

In six consecutive cases of the material under review the weekly working hours were: 76, 65, 74½ (average), 71½, 73½, 76½. The figure in the second case (65) is admittedly lower than the others, but this apparent advantage was offset by the fact that the patient, a charge-hand electro-plater in an aircraft factory, was a night worker, and had been so continuously for four years. Throughout the series studied relatively high wages were found to be the rule, remuneration for skilled tradesmen being commonly £7 to £8—and even up to £10—a week.

Discussion

To avoid confusion and unnecessary multiplication of terms it would perhaps be simplest to apply to the condition under review a term previously used by Tredgold (1933)—namely, that of "acute neurasthenia." It may be recalled that Tredgold did not use this term in a general sense, but restricted its application to a condition in which there occurs "marked failure of mental capacity" and to which "physical fatigue becomes superadded, and the individual suffers from a general nervous exhaustion. In addition to the incapacity for sustained efforts, either mental or physical, there is inability to make decisions, faulty attention and memory, loss of emotional control, and increased irritability."

To persons versed in applied psychology, whether in its social, industrial, or medical aspects, it will be apparent that the common factors enumerated above represent a combination of inducements, moral and material, that may be calculated to stimulate every department of the ego. The appeals of patriotism, self-esteem, the team spirit, and the position of personal responsibility (with associated unconscious concomitant of superiority), though indispensable to the successful prosecution of armed conflict, may, if pressed too far, reach a point when ultimate efficiency and output are threatened. Aside from all idealistic consideration, however, material urges may be no less dangerous. We shall not be surprised if we find that, after several years of unemployment, the skilled artisan welcomes the prospect of work, to say nothing of the opportunity of earning £7 or £8 weekly, even if in turn there is demanded of him continuous overtime and a 70-hour week.

From a study of the case material it is obvious that failures of patients in the series may have been contributed to by factors—personal, individual, constitutional—other than the circumstances of excessive working hours; but such factors—and they are to be found in a proportion of individuals composing any community—may not lead to breakdown unless additional and extreme external stress be applied. It may be that the perfectly adjusted personality would not break down under the conditions described; that in the absence of some constitutional predisposition, or mental conflict such as may derive from underlying discontent or unhappy personal relations, failure is impossible. It is realized that under the sustained and powerful emotional stimulus of a great national cause and effort individuals may achieve levels of performance substantially higher than may be gained in the course of their routine peace-time occupation; in the light of past experience, however, it would seem questionable whether demands so excessive as those described above can be satisfied by workers without jeopardizing, ultimately if not immediately, their total productive capacity, and it is contended that, in the type of case referred to, actual working conditions have been the exciting cause.

It may be argued that these conditions of employment are not obligatory, that the worker who is aware of strain is at liberty to take time off—as, for example, on Saturday afternoon or Sunday. The quality of insight is, however, by no means universal in its distribution, and in practice the inducements, already noted, to working all available hours prove too strong. It may further be objected that a small number of isolated cases referred to a psychiatrist afford an inadequate basis upon which to introduce the problem. There is no disputing, however, the previous scientific findings as to working conditions on the one hand, and on the other the prevalence of the 70-hour week applied to the armament industry in its various aspects throughout the country.

Conclusion

No attempt has been made in these observations to investigate or discuss the subject from the standpoint of industrial psychology in any scientific way. Nor has reference been made to methods of treatment found effective in the cases concerned. While it is true that in the majority prognosis is favourable, the conditions responding satisfactorily to psychological treatment and general measures, the object has been to call attention to the discrepancy between previous scientific findings as to working hours and conditions of work such as are current industrial practice under the exigencies of our present rearmament programme, and thereby to lay emphasis upon prevention as distinct from amelioration. If the nation is to "stay the course" in the most efficient way possible this problem will require to be looked into, and it is felt that a definite case has been made out as to the urgent necessity for detailed scientific investigation in collaboration with those whose duties bring them in touch with working conditions as they affect large groups of workers. The very demand for supreme national effort is also the argument for the closest study concerning productive capacity in its fullest and most lasting sense. The spontaneous, haphazard, and irrelevant remark of a psychoneurotic patient (a fitter), under treatment for a complaint other than anything connected with his work, may summarize and illumine the importance of this question: "Next week we'll be going on seven days—a 70-hour week. The thought comes to me, 'How long shall I stand up to that? How much shall I damage my resources for the future?'"

The annual report for 1938 of the National Association for Supplying Medical Aid by Women to the Women of India (Countess of Dufferin's Fund, including the Women's Medical Service) reveals a gratifying increase in the support of this organization while indicating the great amount of work that still needs even more financial and other kinds of help if the intense demand for its services is to be at all adequately met. A very strong case is presented for enlarging hospitals for women and for building new ones. A tour in the North-Western Province, for example, taken at the request of the Inspector-General of Civil Hospitals showed that the women in that Province, as is also the case in other parts of India, are becoming much more "hospital-minded"; the number of maternity patients has more than doubled there in the last few years. The present hospital accommodation is quite inadequate to meet the demand, and the existing hospitals for women are all overcrowded and understaffed. It is gratifying that the unhealthy "purdah" system has been broken down, but there are still very many Indian women who would rather risk death than enter a general hospital, and a still larger number of women who would much prefer to be treated by members of their own sex for their confinements and for special diseases of women. Hospital equipment needs modernizing, and medical and nursing staffs should be brought more nearly up to the standards existing in Great Britain and the United States. Many local authorities seem to be unable to give proper financial support to the hospitals under their administration.

DOES POLIOMYELITIS AFFECT INTELLECTUAL CAPACITY?

AN INVESTIGATION ON 98 CASES

BY

R. G. GORDON, M.D., D.Sc., F.R.C.P.Ed.

J. A. FRASER ROBERTS, M.A., D.Sc., M.B.,

AND

RUTH GRIFFITHS, M.A., Ph.D.

(From the Burden Mental Research Trust, Stoke Park Colony, Bristol)

The question as to how far infections of the central nervous system have any influence on basal intelligence is one which has not been widely explored. In this country Dawson (1931) has investigated a series of cases of chorea in which he found no variation from the normal, and another of encephalitis lethargica in which he demonstrated a progressive deterioration; but, as far as we can discover, no investigation on the effects of anterior poliomyelitis has been undertaken. It might be said that poliomyelitis, being a disease whose chief incidence falls on the anterior horn cells of the spinal cord, was hardly likely to affect intelligence, but it should be remembered that it is now reasonably certain that the path of invasion is by a droplet infection lodging the virus in the post-nasal mucous membrane, whence it travels by the perineural path through the cribriform plate, and so transcerebrally to its subsequent nidus in the anterior horn cells. Furthermore, many cases show at least transient initial cerebral symptoms, which are sometimes of considerable intensity.

Mollaret (1937) in his chronaxial studies of the nervous system sums up certain experimental results on anterior poliomyelitis, which included the introduction of the virus by non-cerebral routes (intraperitoneal, etc.). The interest of this study is that it suggests the existence of a cerebral disturbance occurring before the evident onset of symptoms. Moreover, this disturbance is found as constantly in abortive or asymptomatic cases as in those which develop typical paralysis. It bears witness without doubt to the constancy of a hitherto unsuspected early encephalitic dissemination of the virus. For these reasons it seemed worth while to attempt to determine whether poliomyelitis affects general intelligence, as measured by standard tests, especially as it is not unusual for parents or teachers to express anxiety as to how far this disease may affect the intellectual as well as the physical integrity of the unfortunate victim.

Selection and Testing of the Group

All the cases were derived from those coming under the scheme of the Bath and Wessex Orthopaedic Hospital and clinics, to the surgical staff of which we wish to express our gratitude for allowing us access to them. All children between the ages of 4 and 16 who during the period of investigation were under treatment at the central hospital for the acute stage of poliomyelitis or its residual effects were tested on the Stanford-Binet scale. In order to increase the numbers, and to include cases the onset of whose disease had occurred several years before the tests were applied, a further group was examined at some of the clinics. The children tested were those who happened to attend on the days of the visits of the psychologist; apart from this there was no selection.

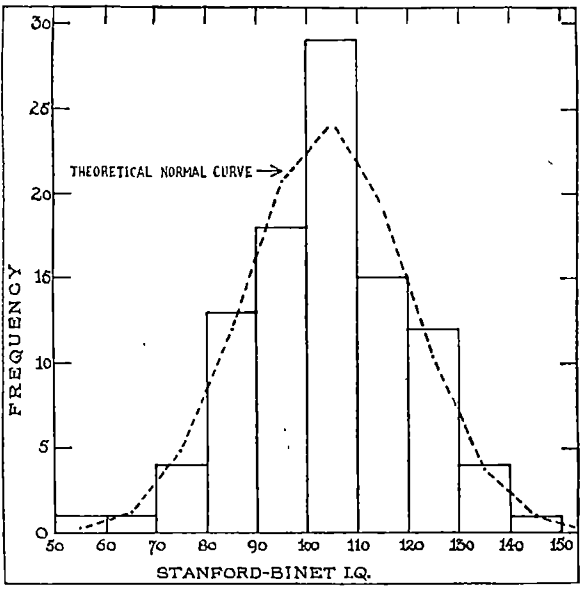
Rather more than a hundred cases were tested, but subsequently this number was reduced to ninety-eight after a very rigid clinical survey with the object of excluding those who did not present unequivocal evidence that their disability was due to poliomyelitis. Some of the cases came from rural areas, others from urban areas, but all were of the economic status represented by the elementary school population. Some had been hospitalized at the onset of the illness; others subsequently, for the purpose of orthopaedic treatment of residual disabilities, whether by operative or other measures; while some had not been hospitalized at all, but had been under observation at the clinics.

Results

The following table shows in somewhat condensed form the Stanford-Binet I.Qs. of the ninety-eight children. The diagram presents the same results graphically.

Binet I.Q.	No. of Cases	Binet I.Q.	No. of Cases
50-59	1	100-109	29
60-69	1	110-119	15
70-79	4	120-129	12
80-89	13	130-139	4
90-99	18	140-149	1

Mean I.Q., 103.91. Standard Deviation, 15.89. (Ungrouped figures.)



The problem is this: Does this sample of children yield the same average result as would a sample of normal children drawn from the general population? Furthermore, does the variability, the spread, of the results indicate a range of variation similar to what would be found in a representative group of healthy children?

The Stanford-Binet scale has been very widely used over many years, and it has been found that an I.Q. of 100 is, in fact, very close to the average I.Q. of the general population. Thus it is clear that the average performance of the present group does not fall below what could confidently be expected from a random group of normal children. A more thorough examination of this point is, however, possible. In recent years a survey of school children, selected by age only, was made in the city of Bath (Roberts and Griffiths, 1937). The city of Bath is a part of the area from which were drawn the patients included in the present study, and represents the most considerable urban district within that area. In view of the fact that it is generally recognized that the mean intelligence in rural areas is somewhat below that in urban areas, it is to be expected that a random sample drawn from the whole area covered by the present study would certainly not yield a sample superior to the previous one.

The Binet testing was carried out by one of us (Ruth Griffiths), who was also responsible for most of the testing in connexion with the Bath survey; such testing in that survey as was carried out by others was standardized in detail to correspond to hers, so that the figures for the two groups are strictly comparable. The mean I.Q. for the Bath school children was 98.8 and the standard deviation 15.2. It will be seen, therefore, that the present group exceeds the Bath group in respect of mean performance, while in variability, as shown by the standard deviation, there is no significant difference.

Actually the present group is significantly higher in mean I.Q. than the previous complete group, but the absolute difference is of course small. The discrepancy may well be due to a difference in age at test. The children composing the present group were considerably younger than those composing the Bath group, and it is known that the Stanford revision is slightly too difficult at older ages and slightly too easy at younger ones (Terman and Merrill, 1937). Small though this effect is, it is probably sufficient to account for the somewhat higher figure yielded by the present group, though that group is too small to permit a demonstration of the slight fall in I.Q. as age increases.

There is therefore very strong evidence that in mean performance a group of children who are suffering from, or have suffered from, poliomyelitis do not fall below the performance that would be shown by a random group of normal children drawn from the general population.

It has already been mentioned that in variability of results, as measured by the standard deviation, the present group does not differ appreciably from the random Bath group or, in fact, from the results obtained by many investigators on school children in various parts of the world. A more precise examination was, however, made, and showed that the distribution of I.Qs., summarized in the preceding table, did not show any significant departure from what would be expected on the basis of the normal curve; this result, too, is what would be yielded by a sample of similar size drawn from the general population. It can be concluded, therefore, that a comparatively large sample, adequate for this discussion, shows clearly that children who suffer from poliomyelitis give just the same average results as do ordinary normal children, and that the variability of the results also, their spread, their range, is simply that of a normal group.

In view of the unequivocal nature of the foregoing results it is of course very unlikely that any subdivision of the children could reveal an association between the level of general intelligence and any special factors. This proved to be the case in regard to all the analyses we have made. The results are set out, accordingly, in very brief form.

1. *Sex Distribution.*—46 girls: mean I.Q. 102.1. 52 boys: mean I.Q. 105.5. The difference is not statistically significant.

2. *Age at Onset of Disease.*—There was no association, as is illustrated by the following table:

Age at Onset	No. of Cases	Mean Binet I.Q.
Less than 4 years	30	104.1
4–7 years	32	103.8
8–14 years	36	103.9
Total	98	103.9

3. *Interval between Onset of Disease and Performance of Test.*—Once again there was no association.

Interval between Onset of Disease and Test	No. of Cases	Mean Binet I.Q.
0–11 months	21	104.5
1–4 years	38	103.7
5–15 years	39	103.8
Total	98	103.9

Thus there is no evidence either of a depression of intelligence which passes off or of a depression which is produced by the after-effects during the years of childhood.

4. *Occurrence of Clinically Recognizable Cerebral Symptoms at Onset of Disease.*—Group 1: None; 60 children. Group 2: Minor symptoms; 22 children. Group 3: Pronounced symptoms; 16 children.

Group	No. of Cases	Mean Binet I.Q.
1	60	103.4
2	22	105.4
3	16	103.8
Total	98	103.9

The occurrence of cerebral symptoms is therefore of no subsequent significance in regard to the level of general intelligence.

Conclusion

This study shows that an attack of poliomyelitis does not, either at the time or subsequently, depress the level of general intelligence as estimated upon the Stanford-Binet scale. The anxious parent may therefore be reassured so far as basal intelligence is concerned, but two other points must be kept in mind by the physician. In the first place the child affected by poliomyelitis may be absent from school for long periods; unless provision is made by home tuition or, as is done in orthopaedic hospitals, by the provision of special educational facilities, his educational achievement may be very much behind that of his contemporaries, even though his basal intelligence is not affected. Secondly, the child crippled by poliomyelitis may, unless care is taken, develop emotional reactions to his environment which may result in serious personality maladjustments; these may determine definite educational backwardness simulating true mental retardation.

THE PREVENTION OF DEFAULTING FROM V.D. TREATMENT CENTRES

BY

C. HAMILTON WILKIE, M.B., Ch.B., B.Sc.

Director of Venereal Diseases Services, Leicester Royal Infirmary

With the recent advent of the new chemotherapeutic methods of treating gonorrhoea there is likely to be a considerable increase of "defaulters" from the venereal disease treatment centre. Defaulters are patients who cease to attend before all the necessary treatment has been given or before the complete tests of cure have been performed. In addition, many will not seek medical aid. They will depend on a limited amount of self-administered chemotherapeutic treatment. Consequently, these patients receive no thorough tests of cure. Should this tendency be allowed to develop an increase of venereal disease is possible. Methods of dealing with the question are discussed below and an analysis of male defaulters at the Leicester V.D. centre follows.

Public V.D. Lectures

The education of the public on the dangers of venereal disease is now an important part of the V.D. scheme in Leicester. It may be of value to record some of the results. Two periods of six years are compared—1926 to 1931, and 1932 to 1937 inclusive. During the first period practically no propaganda was conducted.

At first some people opposed the idea of public lectures on such a subject. Indeed, the term "venereal diseases" was avoided in the public notices which advertised the lectures in 1932. The bills displayed on trams and buses, in factories, in public lavatories, and in the police headquarters and St. John Ambulance headquarters were headed "Lectures on Social Hygiene." In 1933, however, it was considered that even the term "venereal diseases" could appear in public notices. The popularity of the lectures was apparent from the beginning, the lecture halls being crowded. Each lecture, with lantern slide demonstration and discussion, lasted about two hours. I preferred my own set of lantern slides to an obviously acted film. The discussion which followed always proved valuable. Questions had to be stopped after some sixty minutes, otherwise they would have gone on for most of the night. Those asked were surprisingly intelligent, as the following examples show.

Can a person get venereal disease from a lavatory seat? Can one get venereal disease from domestic animals? Does a woman necessarily know when she has venereal disease? Can a man get venereal disease from having sexual intercourse with a woman when her period is on? Does circumcision prevent venereal disease? What is the speaker's opinion on masturbation? Is it always certain that a man will contract venereal disease should he have connexion with a woman who is known to have it (no preventives being used)? What is the speaker's opinion on prostitution? Why do we not educate the public more than we do on the dangers of venereal disease? Why not instruct the civilian population on preventive measures? Should young people contemplating marriage have tests for venereal disease? Is there any danger of contracting venereal disease from blood transfusions? Can venereal disease of the testicle follow a kick on that part? What is meant by "whites"?

After one of the earlier public lectures I was accused of making it appear that venereal disease could be cured too easily. It was argued that I was encouraging promiscuity. My accusers, however, represented only a few of the extremely narrow-minded. Those accusations were made a few years ago and are now forgotten. I wonder what effect the newer chemotherapeutic methods of treatment will have on promiscuous sexual intercourse. Already the "new tablets" have been claimed to be antivenereal, contraceptive, aphrodisiac, and abortifacient (!).

In public lectures on venereal diseases special reference must be made to the non-venereal patient. Attendance at a V.D. centre does not necessarily indicate venereal disease. Every effort should be made to remove the stigma associated with attendance at a V.D. department. The designation "special department" would be better than "venereal disease department." Some centres do use the better term. The importance of the infected patient attending until the completion of treatment and tests of cure must also be stressed. Quite often patients, perhaps defaulters, attend these lectures. It sometimes happens that a few advanced syphilitic patients are present. A ray of hope and encouragement can be of value to them.

Communication with the V.D. Defaulter

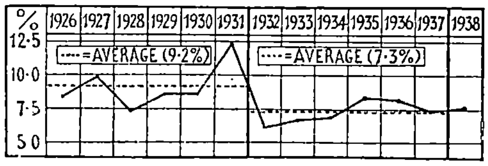
Compulsory notification and treatment of venereal disease is not in force in England at the present time. Some authorities believe that a modified form of compulsion should exist, others believe in strict secrecy and free treatment centres. Under the present arrangements confidence between patient and venereologist must be rigidly kept. We do, however, ask the patient if he has any objection to our writing him should he default. Invariably no objection is given. Of course it is explained that any letter sent will be non-committal in character, not revealing the nature of the complaint or the department attended. Some patients return on receiving such a letter. In other instances the letter is ignored or is returned marked "Not found." A few centres now employ a trained social service worker or almoner to follow up defaulters. I believe that an almoner specially trained for this type of work may be useful for women and children. At the present time I am against the practice of employing an almoner for male cases. The specially trained almoner, usually a lady, no matter how tactful, may inadvertently be responsible for other members of the household getting to know that the son or husband is attending the V.D. centre. The average male patient would not feel that secrecy was in force if a social worker attempted to call on him.

Co-operation between V.D. Officer and General Practitioner

Confidential medical reports between the V.D. officer and the patient's own doctor do not in any way constitute a breach of confidence. It is the practice at this centre to give a written report to the doctor who sends the patient to the V.D. department, and also a final report when cured. Approximately 20 per cent. are referred to us from their own doctor. The general practitioner can often give valuable assistance in persuading contacts or possible congenital patients to attend.

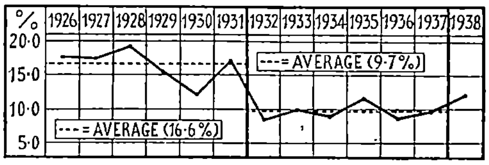
As a result of the chemotherapeutic treatment of gonorrhoea, co-operation between the general practitioner and the venereologist will in future be more important than ever. There is a tendency to give insufficient dosage of the sulphonamide derivatives in acute urethritis and not to follow treatment with the necessary tests of cure. Some cases fail to respond to the newer methods and require additional treatment. The irrigating outfit will still play its part. The complete tests of cure, including urethroscopic examination, sounds, routine blood tests, and prostatic smears, are as essential as ever. Indeed, as a result of late relapses appearing I believe that the observation period should be extended. Some of the spectacular "cures" met with are not so wonderful as at first imagined.

Graph 1.—Yearly percentages of male gonorrhoeal cases on the records who defaulted before completion of treatment. A serious type of defaulter.



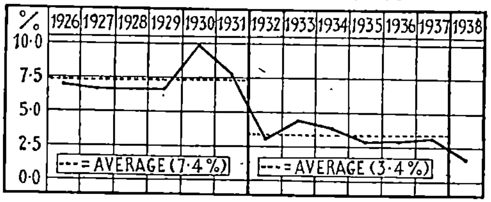
Average 1926–31, 9.2 per cent.; 1932–7, 7.3 per cent.; for 1938, 7.7 per cent. Increase anticipated for 1939.

Graph 2.—Yearly percentages of male gonorrhoeal cases on the records who defaulted after treatment but before tests of cure were completed.



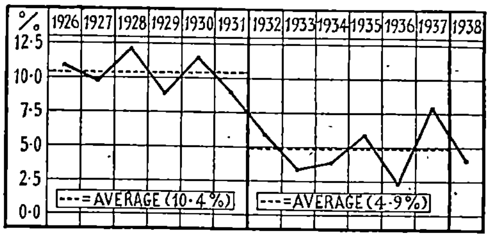
Average 1926–31, 16.6 per cent.; 1932–7, 9.7 per cent.; for 1938, 12.1 per cent. Increase anticipated for 1939.

Graph 3.—Yearly percentages of male syphilitic cases on the records who ceased to attend before completion of one course of injections. A serious type of defaulter, especially if originally primary or secondary syphilis.



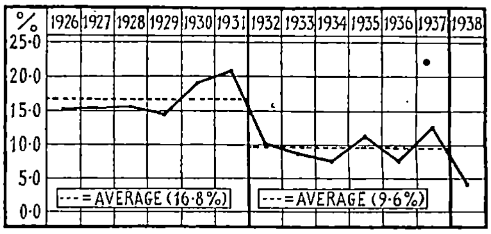
Average 1926–31, 7.4 per cent.; 1932–7, 3.4 per cent.; for 1938, 1.6 per cent. No increase anticipated for 1939.

Graph 4.—Yearly percentages of male syphilitic cases on the records who ceased to attend after completion of treatment, but before final tests of cure (blood W.R. and Kahn tests; C.S.F. examination, and clinical overhaul).



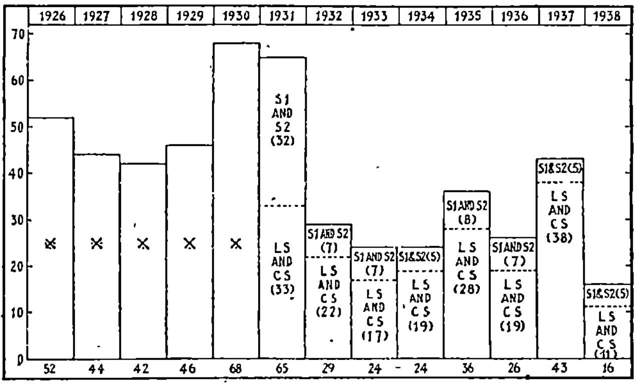
Average 1926–31, 10.4 per cent.; 1932–7, 4.9 per cent.; for 1938, 4.1 per cent. No increase anticipated for 1939.

Graph 5.—Yearly percentages of male syphilitic cases on the records who defaulted before completion of treatment.



Average 1926–31, 16.8 per cent.; 1932–7, 9.6 per cent.; for 1938, 4.3 per cent. No increase anticipated for 1939.

Graph 6.—Analysis of male syphilitic cases who defaulted before completion of treatment.



S 1 = primary syphilis. S 2 = secondary syphilis. L S = all later stages. C S = congenital syphilis. * = all stages (not classified).

Detailed Analysis of Male Defaulters

The six graphs are self-explanatory. They show how the male defaulters at Leicester V.D. centre have varied in the two periods considered in this article. During the first (1926–31) no public lectures were given, while in the second (1932–7) extensive propaganda work and other methods of reducing defaulters were carried out. The defaulters for the year 1938 are also given.

Conclusions

I have no doubt that public lectures on venereal diseases are of value. Certainly we have a few undesirable syphilophobic and gonophobic patients appearing at the clinic after attending a lecture, but this disadvantage is outweighed by the return of defaulters and the attendance of the early infected case.

The graphs given above show that we in Leicester have had a considerable fall in the percentage of defaulters. Two types of gonorrhoeal defaulters dropped from an average of 9.2 to 7.3 per cent., and from 16.6 to 9.7 per cent. respectively. Three types of syphilitic defaulters dropped from an average of 7.4 to 3.4 per cent., from 10.4 to 4.9 per cent., and from 16.8 to 9.6 per cent. This decrease is to some extent due to public lectures.

The confidential letter to defaulters is also responsible for a number returning to the clinic.

Close co-operation between general practitioner and the V.D. specialist is most important, especially in view of the tendency to default at an early date after treatment with the sulphonamide derivatives.

Summary

Methods of reducing defaulters from V.D. treatment and of encouraging patients to attend the treatment centre are considered from the point of view of public lectures, communication with the defaulter, and co-operation between the V.D. officer and the general practitioner.

The results of the adoption of these measures at Leicester are given.

A detailed analysis of male defaulters at the Leicester V.D. centre follows.

Clinical Memoranda

Acute Duodenal Obstruction in a Boy of 8 due to Volvulus of "Volvulus Neonatorum" Type

The following case seems interesting and rare enough to warrant publication.

Case Report

A boy aged 8 was admitted to hospital as a case of suspected appendicitis on February 3, with the following history. On January 8 his doctor was called because he was suffering from abdominal pain and had vomited several times. When seen his pain was not severe, but his parents said he had been in agony during the night. They suggested the pain was due to the fact that he had been to a children's party two days before and had eaten a quantity of nuts. There was no abdominal tenderness, and the boy soon felt better. On January 25 he again vomited twice, but made no complaint of pain. On January 28 he had violent abdominal pains in the night and vomited many times, the vomit being at first yellow and later green. He recovered, but had another attack on January 31. On February 2 his doctor was again called as the boy had pain in the night. When seen he was not distressed and his pulse and temperature were normal, as they had been in the previous attacks. On February 3 his pulse rate rose to 110, he was tender over the appendix area, and he was sent into hospital.

When I first saw him in hospital he was lying comfortably in bed without any pain. His abdomen was somewhat distended, but there was no tenderness, the temperature was 99.2°, and the pulse 104. There was no tenderness on rectal examination. Two hours later the clinical picture was entirely different; the child was in extreme agony, crawling over the bed on all fours, screaming with pain, and rubbing his umbilical region. It was quite impossible to examine him; he was vomiting large quantities of dark green fluid. Although I could not make a definite diagnosis, his symptoms were so urgent that I decided to operate at once.

Under general anaesthesia the abdomen was opened through a paramedian incision. The whole of the small intestine below the duodenum was found to be completely collapsed and empty. The appendix was 8 inches long, but otherwise normal. There was a Meckel's diverticulum 4 inches long and the thickness of a little finger. This was causing no trouble but was removed. The stomach and duodenum were hugely dilated as far as the crossing of the superior mesenteric vessels over the third part of the duodenum. The caecum and the hepatic and splenic flexures of the colon were unduly low in position and provided with a mesentery. The rotation of the gut, however, had been normal to the extent of the caecum being on the right side, although proper fixation had not occurred. Two or three coils of small intestine were encircling the caecum and ascending colon, and gentle traction on the proximal coil tightened these coils like a knot round the large gut. At this stage the patient became extremely cyanosed because vomiting occluded the air-way. The head of the table was tilted down about 30 degrees, a stomach tube was passed, and two pints of green fluid removed, the patient's condition improving immediately. It was now possible to unravel the knots in the intestine, chiefly by rotating the caecum in a clockwise direction. Normal saline was then poured into the peritoneal cavity and the abdomen closed. On the next day there was a certain amount of abdominal colic, which was relieved by eumydrine tablets. The bowels had not been opened for some days, so an enema was given; these had to be repeated at intervals for a month.

A rather stormy convalescence included chest infection, probably from aspirated stomach contents during the anaesthesia. This was treated by sulphapyridine, but the boy's tolerance to this drug was very poor; it soon caused vomiting, and had to be stopped. However, he gradually and steadily improved and was about to be discharged when, together with several other patients in the ward, he developed scarlet fever. This was his final setback, and he was last seen walking about the town looking happy and well.

There have been no abdominal symptoms since the operation was performed some months ago, and I hope, perhaps fondly, that there was enough peritoneal reaction at the site of the volvulus to cause fixation of the ascending colon and so prevent recurrence of the condition. A barium meal and *x*-ray investigation subsequent to the operation showed no abnormality except the low position of the hepatic and splenic flexures of the colon.

The interesting aspects of the case are: (1) The "volvulus neonatorum" syndrome occurring at the age of 8. (2) The complete collapse of the whole of the small gut, including that taking part in the volvulus. This collapse was due to the obstruction of the third part of the duodenum by the twisting and traction of the "duodeno-colic isthmus." (3) The occurrence of several acute attacks with symptomatic recovery between them. (4) The agonizing pain caused by the condition, which was commented on by all who saw the boy during an attack, yet half an hour later there would be very little abnormality to observe.

HERBERT PEARSE, M.D., M.R.C.S.,
Honorary Assistant Surgeon, Taunton and
Somerset Hospital.

Reviews

ABDOMINAL INJURIES IN WAR

The Abdominal Injuries of Warfare. By Gordon Gordon-Taylor, O.B.E., M.A., F.R.C.S., F.R.A.C.S. (Hon.). (Pp. 88; 68 illustrations. 10s. 6d. net.) Bristol: John Wright and Sons; London: Simpkin Marshall. 1939.

This little volume might be described as an illustrated guide to the specimens of abdominal injuries in the war collection at the Royal College of Surgeons of England. Developed after the last war and consisting of specimens supplied personally by surgeons engaged in the field, the collection is unique, and no more opportune time could have been chosen for its description. The value of this description is, however, enhanced by its authorship. Mr. Gordon-Taylor devoted a large period of his war service to a casualty clearing station, so that he speaks from first-hand and most intimate knowledge of his subject. Moreover, many of the cases described were either under his own care or under that of surgeons with whom he was in intimate contact, and this gives to his observations an interest and an importance which are quite exceptional.

In spite of its brevity the volume covers every field of abdominal injury, although of necessity the greater part is devoted to injuries of the intestine. The illustrations throughout are superb, as one might expect from the hands of Mr. Thornton Shiells. The descriptions are brief and concise, and are illuminated by the penetrating observations of the author. In the short space of a review it is impossible to give any adequate idea of the value of the book, and we can only say that we hope that no surgeon will attempt to deal with these injuries until he has read and re-read this volume and has grasped the amazing results which may be obtained in the most desperate conditions by daring surgery. Mr. Gordon-Taylor has once again placed us in his debt.

INCIDENCE OF PEPTIC ULCER

Studies on the Changing Incidence of Peptic Ulcer of the Stomach and Duodenum. By Gunnar Alsted, M.D. With a preface by Professor E. Meulengracht. (Pp. 148; 12 figures; 22 tables. 10s.) Copenhagen: Einar Munksgaard. London: Oxford University Press. 1939.

Recent observations have led to the belief that signs of active or former peptic ulcer are found in between 5 and 20 per cent. of necropsies. The consensus of clinical opinion is that peptic ulcer occurs more often than it did, but this clinically observed increase may be due in part to an improved diagnostic technique. Though we have no certain information as to the changes there may have been in the incidence of peptic ulcer, the ratio of cases of duodenal ulcer to cases of gastric ulcer has certainly undergone a remarkable change during the last hundred years. The older statistics showed that gastric ulcer occurred ten or more times as often as duodenal ulcer, in marked contrast with the present day, when duodenal ulcer occurs four to six times as often as gastric ulcer. Moreover, in the course of the last fifty or sixty years a change has taken place in the sex incidence of peptic ulcer, in that towards the close of the last century the proportion of men to women affected was 1:5 or 1:6, whereas since the war the proportion has been more like 3:1.

In searching for an explanation of these facts Dr. Gunnar Alsted has drawn on the records of the hospitals of Copenhagen, especially the Bispebjerg Hospital, and has brought his results together in a small volume with an introduction by his chief, Professor Meulengracht. Haemorrhage causing haematemesis or melaena, or both, is a striking symptom in 10 to 30 per cent. of cases of peptic ulcer, and, since 80 per cent. or more of manifest haemorrhages are caused by ulcer, it is significant that Dr. Alsted finds the change in the sex incidence of peptic ulcer reflected in cases admitted to hospital on account of manifest haemorrhage. In the statistics from Denmark and abroad the same proportion of men to women as is given by the pathologists and the clinicians from other points of view holds good—that is, since the end of last century the sex ratio has changed from 1:3 to 2:1 or 3:1. Since these gastric haemorrhages are so conspicuous and have probably always manifested themselves in the same way, and resulted almost always in removal of the patient to a hospital, either immediately or after a short space of time, Alsted feels justified in using the statistics of the Copenhagen hospitals to throw light on his problem. On the basis of the annual returns of the hospitals it is shown that in the course of years—from 1876 to 1935—an increase in the number of these cases has taken place which is much greater than would correspond to the growth of the population. The increase applies both to men and to women, but is most pronounced for men.

This rise in the frequency of such haemorrhages in males turns out to be due partly to improvements in diagnosis and partly to the rapidly increasing number of readmissions. The frequency of fresh ulcers has not changed in the course of years, hence the real decrease in the incidence of ulcer in female patients is appreciable. Observations on the incidence of peptic ulcer in other countries and on the incidence of haemorrhage in the Copenhagen hospitals, and the results of a detailed investigation of the cases admitted to one department of the Bispebjerg Hospital over a period of years, confirm Dr. Alsted's opinion that the supposed increase in the frequency of peptic ulcer is exclusively due to an improved diagnostic technique and a growing number of re-admissions. In women there has actually been a great decrease in the frequency of ulcer, and this is the real cause of the change in the ratio of males to females found everywhere. The author also points out that clinical manifestations of peptic ulcer have changed considerably in the course of the last fifty to sixty years. Previously an acute disease, it is now predominantly chronic, and, while formerly localized principally to the body of the stomach, its seat is now commonly the duodenum.

VITAMIN C AND TUBERCULOSIS

Ascorbinsaeurestudien an Gesunden und Tuberkulosekranken. By H. Dagulf. (Pp. 195; 26 figures; 37 tables. No price given.) Göteborg: Elanders Boktryckeri Aktiebolag. 1939.

An appreciable literature is accumulating on the relations of vitamin C and tuberculosis in both the experimental and clinical fields, with conclusions that are conflicting. It is therefore not surprising that the therapeutist is still waiting for an authoritative lead. Dr. Dagulf's monograph, giving a review of past work and his personal investigations, impresses us as a readable, concise, and unbiased presentation of the whole subject. In the first part of the book the author reviews the history of ascorbic acid, methods of determination, and functions. In a chapter on "Ascorbic Acid and Infections" he concludes that the exact part played by vitamin C in relation to infections is not yet clear, and also that it has not yet been established that there are any connexions between vitamin C and tuberculosis. In the last chapter of this part of the book are briefly reviewed other aspects of vitamin C—its relation to blood diseases, digestion, and the specialties of obstetrics, gynaecology, paediatrics, ophthalmology, etc.

In the second part of the book the author describes his own clinical investigations. Contrary to results previously reported, the method of determining the capillary resistance is not a trustworthy clinical test of the vitamin C state in extrapulmonary tuberculosis. Saturation and other tests, however, showed that in this form of the disease the vitamin C saturation was lower than in healthy individuals on a similar diet. Determination of ascorbic acid in the blood also showed decidedly lower figures in the tuberculous than in healthy people. The chief cause for the lower standards in the tuberculous is, according to the author, to be found in the low vitamin C content of their diet. He maintains, moreover, that the ill effects of hypovitaminosis C have been exaggerated. There may be indications for vitamin C therapy in tuberculosis, but they are narrow and their limits are still to be determined.

The monograph concludes with a bibliography of nearly a thousand references.

APPLIED GENETICS

Genetics and the Clinician. By Lindsay Ride, M.A., B.M., B.Ch., M.R.C.S., L.R.C.P. (Pp. 146; 25 figures; 11 tables. 10s. 6d. net.) Bristol: John Wright. London: Simpkin Marshall. 1939.

The author of this book is professor of physiology at the University of Hong Kong and for a number of years has been carrying out investigations on hereditary characteristics, both morphological and physiological, exhibited by several Eastern races. His studies have led him, he states, to a realization of the importance of genetics in human biology and of the need for raising the average level of knowledge among members of the medical profession. He writes as an enthusiast concerned to show the clinician that genetics has a fundamental contribution to make, and, furthermore, that that contribution can be made now and not merely at some future time.

Professor Ride is careful to point out that his book—a very short one—is not intended to be a textbook. He explains that it is a combination of a thesis written some years ago and a university course on human genetics, together with a few additional chapters; this gives the book the character of a series of essays. The preface is dated June, 1936, and this (unless 1936 is a misprint for 1938) explains what would otherwise seem to be serious omissions. Professor Ride was unfortunate in the time chosen to write his book; had he waited for a couple of years he could have added an account of some of the most impressive advances yet made in human genetics—for example, the demonstration of genetic linkage in man, of partial sex linkage, and the estimation of the mutation rate of two or three human genes. If he were writing at the present time he could make out an even stronger case than the one he has so forcibly presented.

It is easy to select a number of features worthy of favourable notice: the chapter on "Heredity and Environment in Medicine" is particularly constructive and helpful; the criticism of those who airily dispose of the evidence pointing to heredity as a factor of importance in the causation of cancer is trenchant and to the point; there are valuable lists of references; the long glossary is truly excellent. Professor Ride states that his modest aim is "to convince a portion of practising clinicians—no matter how small—of the value of applied genetics." He will undoubtedly achieve it.

CHRONIC ARTHRITIS

Chronic Arthritis. By Robert T. Monroe, A.B., M.D. Edited by Henry A. Christian, A.M., M.D., LL.D., Sc.D. (Pp. 84. 8s. 6d. net.) London: Oxford University Press. 1939.

This book furnishes a further addition to the already voluminous literature on the subject, but its practical outlook and sound teaching will appeal to all who are interested in the management of this difficult problem. The American nomenclature is used, and three types of chronic arthritis are described, atrophic and hypertrophic arthritis and the periarticular forms of fibrositis, which include many of the occupational types of "rheumatism," though trauma is named as the most clearly recognized cause of hypertrophic arthritis and is associated with defects of posture which are often occupational. Aetiology is fully dealt with from all aspects in a manner indicating sound judgment and common sense, and the relation between cause and treatment is kept clearly in view. The difference between weather and climate is recognized, which is unusual; the author remarks, "Fortunately a good climate is only a luxury in the treatment of arthritis. Most patients recover in their native atmosphere if they have the determination and the proper care." Terse and striking statements and descriptions of this type are numerous and add to the pleasure of reading the book. The influence of nerve fatigue in arthritis, both atrophic and hypertrophic, is fully dealt with; too often it is overlooked in the latter.

The pathology and clinical features of the different forms are fully described, but the absence of illustrations detracts from the value of the section on *x*-ray appearances. The general arrangement is rather confusing, though it has the advantage of showing the relation of the different types.

Notes on Books

A few years ago irreverent youth amused itself with a game wherein one travelled on top of a bus in London with a companion, to whom he gave with great assurance, and in a loud voice, grossly misleading information, as, for instance, that Madame Tussaud's was the Bank of England, or St. Thomas's Hospital was the B.B.C. When a stranger could be induced to volunteer a correction of the error, that counted one point to the "server," who then became "striker" to his friend's "service." There is some ground for a suspicion that the author of *Doctor—Here's Your Hat* (Cape, 10s. 6d.) is trying to play this game on his readers and his reviewer. To begin with, Dr. **Joseph A. Jerger** makes the statement that his father's occupation involved buying—not prospecting for—diamonds in South Africa for Cecil Rhodes during the 'nineties. If one suggested that selling scuttlefuls of coal to a Wallsend colliery would be just as profitable, Dr. Jerger would no doubt reply, "Fifteen—love." Then we find him landing at Capetown a few days after the outbreak of the Boer War and taking a train for the Transvaal at a date when no railway trains could possibly get within several hundred miles of that State—"Thirty—love." He then buys a camel ("Forty—love") and sets off on it across the veld; contracts typhoid fever, and regains consciousness in a hospital at Capetown—civil or military not stated—where arrangements are made to send his body to Australia if he should die. We give

Dr. Jerger best: game, set, and match to him. After this promising beginning he develops his real thesis, that (in the U.S.A.) there is too much specialization and not enough respect paid to the general practitioner. Incidentally, his account of his medical studies in America makes one wonder, not that there should be an occasional incompetent doctor over there, but that there should be an occasional competent one. His professional autobiography is full of amusing yarns; but how much of it is a leg-pull, on the pattern of the opening pages, passes the wit of at least one Englishman to guess. It is to be hoped, at any rate, that he is overstating his case when he declares that three-fifths of the recruits inspected for the U.S.A. Army during the war were infected with venereal disease.

The fact that a second edition of *Bacteria in Relation to the Milk Supply* by C. H. CHALMERS (Arnold, 6s.) has been called for within four years shows that this little work is filling a useful place in the field of dairy bacteriology. Substantial alterations have been introduced into the new edition so as to deal more fully with such subjects as the methylene-blue reduction and the phosphatase tests. It may be noted that the temperature at which the water-bath used in the official method of performing the methylene-blue reduction test is given erroneously as 37° ± 0.5°; the correct figure is 37.5° ± 0.5°C. Similarly the preparation of the control tubes differs from that laid down in the official order. The section on water examinations is based on the original edition of the Ministry of Health's Report No. 71. A new edition of this report, which readers by Chalmers's work would do well to consult, has just been published in which considerable alterations are recommended. Incidentally, Fildes spells his name with an "s."

Poisonous Plants of the United States by Professor W. C. MUENSCHER is a volume in a series on rural science which covers a wide variety of aspects of agriculture. The author classifies the poisonous plants in two main groups: those which are poisonous under all conditions and those which are poisonous under special conditions. The second group is of considerable medical interest. It includes the plants causing dermatitis (about 100 listed), those causing photosensitization, and cyanogenetic plants, etc. In this connexion a relatively new danger has been recognized: certain plants can absorb selenium compounds in large enough quantities to make them poisonous to animals, and this has been established as the cause of "alkali disease" and "blind staggers" in cattle and horses in areas where seleniferous Cretaceous or Eocene shales occur. The main part of the volume consists of a description of poisonous plants classified according to their natural orders, and the text is followed by ten pages of references. In general the volume gives a brief but competent account of a subject which is of primary importance to agriculture and also presents many problems of general pharmacological interest. It is published by Macmillan at 15s.

Volume III of *Thorpe's Dictionary of Applied Chemistry* (fourth edition) covers subjects from Chemical Calculation to Diffusion. It is published by Longmans, Green and Company at 63s. A considerable proportion of the volume deals with subjects of medical interest—for example, chloroform, choline compounds, cinchona alkaloids, cocaine, cod-liver oil, creatinine. The article on cod-liver oil deserves special mention, for it gives a particularly clear account of the history, preparation, and properties of this drug. Chemical warfare and chemical warfare defence are two subjects of topical interest that together occupy sixteen pages. Some interesting facts mentioned are that the content of gas as per cent. of total weight is about 50 in the case of air bombs as compared with 10 in the case of shells. About fifty different compounds are described. The most potent toxic agent appears to be diphenyl cyanoarsine, which is used in the form of a smoke and acts as a lung irritant in a concentration of one part in 170 millions. In relation to chemical defence it is mentioned that activated charcoal is still the basic constituent of most respirators, but the introduction of smokes has called for the addition of a filtering mechanism.

May's Chemistry of Synthetic Drugs first appeared thirty years ago and has now reached its fourth edition (Longmans, Green, 21s.). It is seventeen years since the third edition was published and the text has been almost completely rewritten by Dr. PERCY MAY and Dr. MALCOLM DYSON. The new volume includes synthetic vitamins and endocrines. Though the number of new synthetic drugs which are introduced into clinical practice is large it represents a very small proportion of the total number of compounds investigated, and this volume, which is of moderate size (370 pages), only covers a small part of the field. The material has, however, been selected with care, and the authors give an interesting survey of an important and rapidly advancing subject.

Writing on *Le Syndrome "Hémorragie du Nouveau-Né"* (Masson, 26 fr.), Dr. H. JAHIER has allowed himself to be influenced too much by his medical teachers' views on congenital syphilis, for he spoils an otherwise excellent monograph on an important and interesting subject by concluding that this infection is the only complete explanation for the various manifestations of the syndrome. Fortunately he still believes that the supply of adult blood to the infant constitutes the essential part of treatment, although his choice of the longitudinal sinus, approached at the site of the posterior fontanelle, will not commend itself to workers in other countries, who find the majority of infants with this malady are cured by intramuscular injection.

Die Eiweisskörper des Blutplasmas, edited by Drs. H. BENNHOLD, E. KYLIN, and Professor RUSZNYAK, is published by Theodor Steinkopff. It contains articles by various authors from Germany, Hungary, Sweden and Denmark. The first half of the volume deals with the physical chemistry and biochemistry of the proteins of blood plasma and the second half with chemical problems. Professor Rusznyak gives a short but clear survey of the difficult problems associated with oedema. He shows that lowering of the colloid osmotic pressure of the serum is one important factor in the production of this complex condition. The volume concludes with a general review by Dr. E. Kylin of the clinical importance of plasma proteins. He explains that the present work is in the nature of a survey of existing knowledge, and has been compiled with the intention of stimulating and assisting further research in this very difficult but important field.

Preparations and Appliances

POLYVALENT VITAMIN CONCENTRATE

Abecedin (Messrs. H. R. Napp Ltd.) is the name of preparations containing vitamins A, B_1, B_2, C, and D_3. This mixture is supplied in tablets and as an emulsion.

Polyvalent vitamin concentrates provide a very convenient method for the prevention or treatment of vitamin deficiency. The chief difficulty is to produce such mixtures in a stable form. The vendors state that control specimens of their tablets showed no appreciable deterioration in vitamin content after storage for two years. They point out that this applies to unopened packages, and that deterioration by air contact may occur after the bottle has been opened.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY OCTOBER 21 1939

THE PURSUIT OF LONGEVITY

The will to live, the quest for longevity, is the most deeply rooted and persistent of the biological characteristics of protoplasm organized into human individuals. In one of the lectures before the New York Academy of Medicine, published in a recent collection,[1] Professor Raymond Pearl points out that though at the beginning of each person's life this urge to survival is wholly unconscious—just a part of living like digestion or respiration—later on this underlying protoplasmic will to live, the vital momentum, is supplemented in the individual by a conscious search for longevity. Virtually all who live to seventy years and upwards think of little else but about what they should do to preserve their health so that they may keep on living longer. The octogenarian or nonagenarian may be in wretched health and altogether having a bad time of it, but even so his normal instincts are for keeping on. For the consideration of the chances of survival of an individual, and of the means by which these may be increased, statistical methods of examination of life tables are used. Professor Pearl illustrates the function of survivorship of individuals of various ages in the form of a ladder of life, broad based and tapering at the top to which the individual is trying to attain. By comparison of present-day statistics with the life tables of the United States at the end of last century two interesting facts emerge. In the last fifty years or so the prospects for duration of the journey of life have much improved; but it is the average duration of life that has been altered, and this has been accomplished through progress in medicine and improvement in the public health, chiefly in the lowest of first ten-year period. In 1890 only 72 per cent. of boy babies in the United States reached ten years of age; now 91 per cent. do. The span of human life has not been altered, however, and there is no present prospect that it soon will be. Because more get over the early and very difficult stages, absolutely more survive at later ages; but those who attain the age of seventy now actually do not do so well relatively, on the average, in the way of further survival to still higher ages as did the stalwarts of 1890.

The problem of the search for longevity involves attempting to answer the question why it is that some individuals alive at any given age will live thereafter longer than others. The shrewd general impression of a wise physician who spent his own life in a region where longevity was a common phenomenon, Dr. Oliver Wendell Holmes, is summed up in the often-quoted assertion that if one is setting out to achieve threescore years and twenty, the first thing to be done, some years before birth, is to advertise for a couple of parents both belonging to long-lived families. Professor Pearl is able to support this impression by the results of exact quantitative investigation. From these it emerges that people who live to a great age have immediate ancestors (parents and grandparents) who are on the average definitely longer lived than the corresponding ancestors of the general run of the population; and, further, this hereditary influence promoting longevity is between two and three times as great relatively for parents as it is for grandparents. The importance of inheritance is emphasized by comparing statistics of long-lived as against short-lived children and finding that the long-lived children had fathers who lived much longer than the fathers of short-lived children. Corresponding life tables for mothers tell the same sort of story. Further, in another series the expectation of life of the sons of fathers who died young is less than that of the sons of moderately long-lived fathers and still less than that of the sons of extremely long-lived fathers.

Besides the inherited biological constitution of each individual, which is one of the major factors in the probable length of life of the person and which appears to be associated with a number of structural and physiological characteristics that are being slowly determined, there must of course be environmental aspects of the picture. The factors of use of alcoholic beverages and of tobacco have been investigated. One of Professor Pearl's studies published in 1926 led to the conclusion that moderate drinking does not significantly shorten life when compared with total abstention from alcohol, while heavy drinking does seriously diminish the length of life. And as a result of a hitherto unpublished series of investigations of a group of nearly 7,000 men the conclusion is reached that smoking tobacco is definitely associated with an impairment of life duration, and that the amount or degree of this impairment increased as the habitual amount of smoking increased. Further statistics appear to throw light on the question whether hard physical labour tends to shorten life. Apparently before the age of forty is attained it makes no difference in the rate of mortality whether the occupation involves light or physical labour. After roughly the age of 40–45 it seems that a man shortens his life by definite amounts in proportion as he performs physically heavy labour.

The literature of longevity is full of advice, recipes, and precepts for the attainment of length of days.

---

[1] *Landmarks in Medicine. Laity Lectures of the New York Academy of Medicine.* By various contributors. Introduction by James Alexander Miller, M.D. London: D. Appleton-Century Company. (8s. 6d.)

Reviewing the professor's figures in order to seek some broad generalization for individual guidance, in only one outstanding respect besides great longevity did the long lives differ from the rest of mankind on the whole. That is in the fact that a vast majority of these extremely old folk were of a placid temperament, not given to worry: they had taken life at an even, unhurried pace. For a variety of forms—including plants, various lower animals, insects, and men—the length of life is generally in inverse proportion to the rate of living.

RURAL HEALTH ORGANIZATION

The League of Nations had arranged for a European Conference on Rural Life to be held at Geneva in October this year. In preparation for this the League prepared a number of publications in pamphlet or booklet form described as "general technical documentary material." Among them are several which deal with nutrition and rural housing, and two which have a direct and important bearing upon medical services. One is a *General Survey of Medico-social Policy in Rural Areas*, issued by the League's Health Organization,[1] and the other deals with *Sickness Insurance and Rural Medical Assistance*, and is issued by the International Labour Office.[2] The two documents are closely connected one with the other, and they contain information and conclusions of great interest to all who have any concern with social medicine. Many of the facts set out and problems discussed have to do with medical organization and services in general, and not merely with those of rural areas; but it is made clear that the circumstances of rural and agricultural populations give rise to peculiar needs, require special adaptations, and certainly call for the provision of health and medical services to no less extent than that now so widely given to industrial communities. This is true even of England, Belgium, and Holland, where the population lives mainly in towns, and of Switzerland and the Scandinavian countries, where the peasant population represents a larger proportion but where farms and rural dwellings have, speaking generally, modern equipment. Still more is this the case in other countries, including parts of Scotland, France, and Germany, where there is a relatively large but scattered agricultural people farming along traditional lines.

It is satisfactory to discover from a survey which includes all these varying conditions that the provision of health services and medical care now established in Great Britain is, so far as it extends, second to none in quality and effectiveness, and that the proposals made by the British Medical Association in its scheme for a General Medical Service for the Nation are almost exactly those which international experience and thought indicate as the most suitable and efficient, and this not merely in regard to the nature of the professional service but also in regard to the main executive and financial arrangements suggested for its administration. Adaptability to local conditions within reasonable limits must be an essential feature of all such schemes. It is possible, within Great Britain, that the conditions in England and Wales on the one hand and Scotland on the other differ sufficiently to make somewhat diverse administrative, or even financial, arrangements advisable. Indeed, at present, as is well known, there are two different systems of medical provision operating within Scotland itself. In some countries it has been found possible to include hospital provision within an insurance scheme; with us such provision has developed, and is developing, on different lines, which seem to prevent such inclusion but allow of a very close association being formed with other medical services in accordance with the B.M.A. plan. Consultant and specialist services are evidently best supplied along with institutional care. In some countries, too, "insurance institutes" (an analogue of our "approved societies" but by no means identical therewith) have been given fairly wide powers in relation to public health, whereas here we shall no doubt continue to look to local health authorities for this purpose. But as to the best method of financing and arranging the collective organization of medical care the Health and Labour Offices of the League of Nations have no doubt. The insurance method has pronounced advantages over any other, including that of entrusting it to practitioners appointed and paid by public authorities; and of the several kinds of insurance schemes that of compulsory sickness insurance for wage earners, their families, and others of similar economic position is to be preferred. It is the scheme which has been most commonly adopted and is working well.

Two other conclusions may well be noted. One is the essential value of properly conducted popular education in health. The other is the need for training the medical profession for the accomplishment of its preventive and social duties. A well-expressed paragraph on this matter is worthy of quotation:

> "Doctors who have been practising for twenty years or more have only received training in the purely technical aspects of hygiene. Although the scope of instruction has been broadened, it remains true that faculties of medicine, the medical press, medical associations, and the profession itself still concentrate on laboratory research, refinements of diagnosis, and new methods of treatment. The preventive and social aspects of medicine are no longer ignored, but little more is done than to make passing reference to them. They still do not permeate teaching nor figure prominently in university examinations, press articles, papers read to learned societies, or debates in

professional circles. At the same time it is being realized that doctors have to concern themselves not only with the fate of sick persons but also in that of the community as a whole. Medical students must therefore be given a better understanding of their future preventive and social duties, while practitioners should be brought to realize that they represent the main line of defence of the health of the community."

THERAPEUTIC REQUIREMENTS IN WAR

Before the outbreak of war large stocks of drugs and therapeutic substances had been accumulated in this country, and the arrangements made by the Government are designed to secure that these stocks should be augmented as required. The British Pharmacopoeia Commission is already engaged upon modifications of the formulae of the *British Pharmacoepia* to meet the exigencies of war time, and subsequently revisions may be expected of the *British Pharmaceutical Codex* and the *National Formulary* for national health insurance purposes. In the meanwhile, owing to the strain imposed upon medical services and the country by the outbreak of war, the utmost economy is necessary in the prescription of drugs. As briefly announced in our last issue, the Medical Research Council, at the invitation of the Ministry of Health, has formed a Therapeutic Requirements Subcommittee to advise the Ministry and the medical and the pharmaceutical professions on matters relating to economy in the use of drugs. Where several variants of a particular drug are known, or where there are several remedies for a particular disease, it may be desirable, on grounds of economy, to concentrate upon the manufacture of a single preparation or compound. The raw materials which go to the making of many therapeutic substances are imported from abroad. In the case of other substances supplies available for the medical profession may be diminished by reason of an abnormal demand from other essential services. The newly appointed subcommittee will endeavour to ensure the most effective and most economical use of drugs and therapeutic substances, bearing in mind these and other considerations. The full co-operation of all medical practitioners is needed in order to prevent waste in dispensing. All communications with regard to the work of the Therapeutic Requirements Subcommittee should be addressed to Dr. C. H. Hampshire, 44, Hallam Street, London, W.1.

CHEMOTHERAPY OF MALARIA

Contributions to the already extensive literature on the control and treatment of malaria by drugs appear with increasing frequency, and demonstrate the clinical research which is going on continuously among workers in tropical medicine. Just over a year ago we discussed in these columns[1] the findings reported by the Health Organization of the League of Nations,[2] and the broad conclusion was that there was no drug which was capable of acting as a certain and practical causal prophylactic agent against malaria. Field,[3] from the Federated Malay States, confirms that this is still the general position, but his work and that of others indicate that although the chemotherapeutic control of malaria is not yet in sight, the signs are by no means discouraging. Sinton, Hulton, and Shute[4] have shown that sulphanilamide is capable experimentally of preventing infection with *P. falciparum,* but although this is of considerable chemotherapeutic interest it has, as yet, no direct practical application. Plasmoquine, which is peculiarly lethal to sporozoites, can only act as a prophylactic in doses bordering on the toxic. This does not mean that all drug treatment aimed at preventing malaria is necessarily useless, although Field appears to doubt whether under the conditions obtaining in Malaya any adequate form of mass chemoprophylaxis is feasible. Atebrin prophylaxis gives more effective control of malaria than does quinine, but the continuous administration of atebrin is hardly justifiable until more is known of its ultimate effects on the human system. Quinine appears to be without serious side effects, but its regular daily administration to large population groups in Malaya is difficult to organize, and it is less effective when given at greater intervals. On the other hand, in Italy and Algeria quinine prophylaxis is regarded as a malarial control measure of great practical utility. Although experience attests to the prophylactic effect of quinine or atebrin, under suitable conditions, in preventing infections reaching a level where clinical symptoms are produced, such infections are not necessarily eradicated, as is shown by the rise in parasite rate and by the fever which follows withdrawal of the drugs. For the treatment of the acute attacks quinine or atebrin are the drugs of choice; the daily administration of 2 grammes of quinine or 0.3 gramme of atebrin in three divided doses suffices to clear the parasites within a few days, but unfortunately relapses are not infrequent. Plasmoquine, however, which is of little value itself in the actual control of the acute attack, is said to diminish the incidence of relapse when associated with the quinine or atebrin treatment, and it is also an effective gametocidal agent against the crescents of *P. falciparum,* which are relatively unaffected by the other two drugs. Smith,[5] Lipscomb,[6] and Boyd[7] recently drew attention to the effect of plasmoquine combined with atebrin in diminishing relapses. In 1934 the Malaria Treatment Centre at Kasauli, to which were sent the recurrently relapsing cases of malaria, was closed for want of material, and Boyd attributed this result to the effect of plasmoquine treatment. On the other hand, Whittingham[8] stated that, although it was agreed that the new synthetic drugs reduced the relapse rate, the low rates observed by Smith, Lipscomb, and Boyd were only true up to a period of about three months after treatment was started, and that if the patients were watched for longer periods 20 to 25 per cent. relapsed. In practice Field appear to prefer to give plasmoquine after the other drugs, and while most will agree with this in the case of atebrin, many use quinine and plasmoquine simultaneously, as this shortens the course of treatment and appears to be without undue danger from increased toxic effects. The remarkable activity of the sulphonamide compounds in bacterial infections naturally leads to their being tried against other organisms, but so far as human malaria is concerned Niven's[9] conclusion concerning prontosil appears sound—namely, that although it had some lethal action on malarial parasites, especially *P. falciparum*, it had no place in the practical treatment of malaria owing to its low efficiency, possible toxicity, and relatively high cost. On *P. knowlesi*, however, a parasite of simian malaria, sulphonamide compounds — namely, soluseptasine, prontosil, and particularly sulphapyridine—have a remarkable action, as shown by Chopra and Das Gupta.[10] [11] [12] A number of other dissimilar compounds are capable of exerting some therapeutic effect in malaria. The action of arsenobenzol against *P. vivax* is well known, and Glyn-Hughes, Lourie, and Yorke[13] have shown this same infection to be susceptible to the action of undecane diamidine.

THE MECHANISM OF DIABETES INSIPIDUS

The association of the hypothalamus and the pituitary gland with the control of water metabolism has been shown by the study of pathological material obtained from cases of diabetes insipidus in man and the production of the syndrome in experimental animals. The control of the enormous polyuria in human beings by injections of pituitrin is paralleled by the similar control secured in experimental polyurias. The existence of an antidiuretic substance or hormone in the posterior pituitary is well established, but the precise mechanism responsible for the diuresis itself is not clear. There is evidence that the anterior pituitary must somehow be involved and also that it possesses a diuretic substance. The importance of the anterior pituitary in this connexion was first emphasized by von Hann over twenty years ago. It has always been significant that, whereas removal of the posterior lobe leads to polyuria, lasting polyuria never follows total hypophysectomy. In a recent paper Biggart and Alexander[14] report a series of experiments on diabetes insipidus induced in dogs. Small localized lesions 1 to 2 mm. in diameter were carefully produced with the diathermy needle in selected regions of the hypothalamus. Out of forty-nine animals thus treated, fourteen died as a result of the operation, thirteen developed a transitory post-operative polyuria, fourteen developed a condition of experimental diabetes insipidus, and six showed no change in urinary output. Detailed histological study of the lesions showed that if they were unilateral no polyuria resulted. The effective lesions were bilateral and in the anterior hypothalamus, the supra-orbital nuclei were destroyed, and in the majority of cases the lesions were so placed that any fibres running from the nuclei paraventriculares to the supra-optic nuclei were severed. As a result of the lesions the posterior lobe became atrophied, but the pars intermedia and the anterior lobe were not affected. The polyuria produced by these hypothalamic lesions was complex and had three distinct phases: a primary phase of transient polyuria lasting from one to six days; a secondary phase of return to normal urinary output; and a final tertiary phase of persistent polyuria simulating diabetes insipidus lasting apparently indefinitely. The daily urinary output in the different phases was, in round figures: pre-operative 500 to 600 c.cm.; primary phase 1,500 to 3,500 c.cm.; secondary phase 500 to 600 c.cm.; tertiary 1,500 to 3,500 c.cm. In the tertiary phase of established polyuria the animals were quite healthy and there was no apparent reason why they should not have continued to old age. Injection of pituitrin in this phase invariably reduced the urinary output to normal, but the primary phase was unaccountably resistant to such treatment. Thyroid, in doses having no effect on the urinary output of normal dogs, increased the polyuria of the tertiary phase in all the cases except one in which there was a diminution. Neither eucortone nor oestrin had any definite effects on the polyuria, which is of interest in view of the known inhibitory action of oestrin on the gonadotrophic activity of the anterior lobe. A striking and persistent decrease in urinary excretion in the tertiary phase could be produced by hypophysectomy or pancreatectomy. It is apparent that the mechanism of experimental diabetes insipidus is very complex. The hypothalamus and posterior lobe of the pituitary must be regarded as a neuro-hormonal functional unit in respect of water metabolism, and the supra-optic tract would seem to constitute the motor secretory path for the control of the secretion of the antidiuretic factor. From the work of Ranson and his colleagues in America it may be concluded that the hypothalamic lesions lead to actual cessation of elaboration of the antidiuretic hormone. Though the tertiary phase of the experimental polyuria can be readily explained on these lines, the secondary and primary phases cannot. For the secondary phase it is possible to suppose that there is a liberation of the stores of antidiuretic hormone which are known to exist in the normal posterior lobe. Unfortunately for such a hypothesis removal of the posterior lobe and stalk has been followed by a latent period similar to that found after hypothalamic lesions, before establishment of the permanent polyuria. Still more difficult to understand is the primary phase, for this occurs at a time when there must be adequate amounts of antidiuretic hormone in the posterior lobe. This phase also is refractory to injections of pituitrin, which have been stated in some reports to increase the polyuria. Biggart and Alexander consider that this primary polyuria is unrelated to the effects of the permanent hypothalamic lesion of the tertiary phase, and that its mechanism is quite obscure. The primary phase is not due to effects from the anterior pituitary, because it occurs even after complete hypophysectomy; further, there are no direct nerve connexions from the hypothalamus to the anterior pituitary. The possibility that hypothalamic lesions and hypophysectomy may have some transitory direct effect upon renal function is not considered in the paper by Biggart and Alexander. Such a possibility may deserve study.

LABELS FOR COSMETICS

They evidently take their cosmetics seriously in America. It has long been known that the trade in cosmetic preparations comes surprisingly high up the list of trades classified according to the magnitude of their annual turnover in the United States, and superficial inspection shows that its importance is growing with great rapidity in this country also. Vast sections of womankind, which a few years ago spent little or nothing on cosmetic preparations, now devote a considerable proportion of their weekly earnings to beauty culture, sometimes to the neglect, it is rumoured, of their meals. Here it is still practically unfettered by legislative regulation and manufacturers can make any claims they please for their products, and they take advantage of this licence by vaunting their ability in the therapeutic field. Common examples of this practice are lotions for the cure and prevention of blackheads, for the restoration of the growth and colour of the hair, for the eradication of wrinkles. Such claims are no longer permitted to the cosmetic manufacturer in the United States. It seems that a distinct line has now been drawn between the cosmetic care of the skin and its appendages and therapeutic measures. According to a leader in the *Journal of the American Medical Association* of September 2 legislation was passed in 1938 consisting of the Wheeler-Lea Act and a Food, Drug, and Cosmetic Act; these measures effectively regulate the trade in cosmetics. The Federal Trade Commission can now require a manufacturer to show cause for the claims he makes for his preparations. If such cause cannot be shown a "cease and desist" order can be issued to prevent such claims. For example, manufacturers are not allowed to use the word "non-allergic." This is because even the simplest preparation may be "allergenic," or, in plain language, irritating to susceptible persons. Manufacturers have also been notified that certain names and statements used on the labels of cosmetics are not permitted. Those who are accustomed to the go-as-you-please policy adopted in such matters in this country will be astonished at the strictness of the American regulations. It is forbidden to advertise depilatories for permanent removal of the hair, products represented as depilatories but which merely bleach the hair, hair growers or restorers, skin food, wrinkle eradicators, cosmetics represented as valuable because of their vitamin content, and many others which are the commonplaces of the advertising columns not only in the newspapers and fashion periodicals but also in Government publications such as the convenient stamp books issued by the Post Office, which are full of the advertisements of patent medicine vendors. One would have thought that official circles would have excluded advertisements of this nature from their publications, but such is not the case, and so far the British Medical Association has protested in vain. It is evident that in the U.S.A. either public opinion is in advance of this country in such matters or the authorities have determined to do more to protect the population against the wiles of the cosmetic manufacturer and their own credulity than our rulers are yet prepared to do in the British Isles.

OPHTHALMOLOGICAL MONOGRAPHS

Documenta Ophthalmologica[1] represents a welcome departure in ophthalmic literature. Ophthalmology is well served by its journals and has a rich textbook literature. It is otherwise with monographs on special aspects. Some periodicals like the *British Journal of Ophthalmology* and the *Acta Ophthalmologica* do indeed publish special supplements to overcome this defect, but the financial difficulties in bringing out monographs on subjects that have a limited interest are real. The first issue of the new venture is an ambitious effort to place monograph publications on the same basis as periodical literature with its wider appeal. It contains an excellent review on the process of light adaptation of the retina by Professor R. Granit of Helsingfors written in English. Dr. P. Baillart contributes an extensive discussion on the retinal circulation; Dr. A. Magitot supplies one on the symptomatology pathogenesis of glaucoma; Drs. Nordmann and Reiss deal with the chemico-physical aspect of cataract formation. These three contributions are in French. There are two articles written in German: one by Dr. F. P. Fischer of Utrecht, who deals with the water contents of the eye; and the other by Dr. P. Karrer of Zurich, who discusses the significance of carotinoids for the eye. The editor contributes an extensive discussion on the vitamins in ophthalmology in Italian. The scope of these articles is best indicated by the fact that their standard equals that of the best contributions to the well-known *Ergebnisse* published in German. The judicious mixture of clinical and academic material represented by these seven monographs is in itself a contribution to the postgraduate education of ophthalmologists. How thoroughly the subject-matter is reviewed may be gathered from the fact that the article on vitamins carries no fewer than 700 references to the literature. *Documenta Ophthalmologica* is promised in instalments of one each year, and we hope the war will not compel the publishers to break their word.

The George Alexander Gibson Lecture will be delivered before the Royal College of Physicians of Edinburgh by Dr. J. Crighton Bramwell, F.R.C.P., in the Hall of the College, 9, Queen Street, Edinburgh, on Tuesday, October 24, at 5 p.m. His subject is "Blood Pressure."

WAR WOUNDS AND AIR RAID CASUALTIES

The following article is a supplement to the series of lectures on war wounds and air raid casualties printed in these columns

DETONATION OF HIGH EXPLOSIVE IN SHELL AND BOMB, AND ITS EFFECTS

BY

DAVID DALE LOGAN, D.S.O., M.D., F.R.F.P.S.G. D.P.H., M.I.M.E.

Lieutenant-Colonel, R.A.M.C. (Ret.)

PART I

In the official *Medical History of the War,* in order to show how little novelty there is in warfare and to point out that mining dates back to remote antiquity, I quoted an ancient historian who described the use of asphyxiating gas in mining at the Siege of Ambracia in the year 189 B.C. On that occasion the Aetolians filled jars with feathers. These feathers were then set on fire and the resulting smoke blown by bellows into the faces of the Romans. 189 B.C.! Yet the method adopted by the Germans more than a thousand years later was somewhat similar.

In France, in 1917, a group of collieries in the Bethune district was one of the few remaining fields in active operation. Although one of the collieries, Fosse 8, in this very important mine system was in enemy hands, and all the shaft heads and the mining villages of Annequin, Vermelles, Philosophe, etc., had been frequently shelled, the French had been able to continue working. At the height of the submarine menace, when there was an urgent demand for coal by the French, the Germans made a determined effort to stop production in these collieries. Unfortunately the French had delayed building off Fosse 8, which was still used as a downcast shaft. Great quantities of chloropicrin gas were thrown down this shaft. Powerful fans, the modern development of the bellows used by the Aetolians, were installed in one of the collieries. These carried the gas to all quarters of the system, killing many French miners who were at work, and also members of a British tunnelling company who were on guard. The gas was so concentrated as to render respirators useless.

Gas warfare, as it is understood to-day, is the natural evolution of the use of explosives and dates back to the sixteenth century, when gunpowder revolutionized warfare. With its introduction the possibilities of offensive mining in all phases of fortress warfare greatly increased. In the sixteenth and seventeenth centuries gas poisoning from the fumes of exploded gunpowder was of frequent occurrence.

Is Gas Warfare Inhuman ?

History shows that every new weapon has met with a hostile reception—inhuman, barbarous, unchivalrous, being common epithets to denounce their use. Among the vast majority of people in this country gas warfare is still regarded as the last word in barbarism. One reason, then, why the use of gas by the Germans raised such an outcry was that it was a new weapon against which there was no defence. It was, moreover, a weapon regarding which there was almost universal ignorance. Very few doctors in this country knew much about gas poisoning and the literature on the subject was very meagre. Everyone knows that by using it the Germans violated the agreement they signed at the Hague Congress in 1899. "The contracting Powers agree to abstain from the use of projectiles the object of which is the diffusion of asphyxiating or deleterious gases." I think it both instructive and interesting to recall a fact which is not nearly so well known: that the United States was one of the few Powers which did not sign that agreement. In my opinion, educated Americans have a better and more correct scientific knowledge and value of chemical warfare than the British. One of the reasons very properly brought forward by Admiral Mahan, the American delegate, was that the reproach of cruelty and perfidy addressed against the use of gas shells had also been uttered against firearms and torpedoes, although both were now employed without scruple. He insisted that

> "it was illogical and not demonstrably humane to be tender about asphyxiating men with gas when all were prepared to admit that it was allowable to blow the bottom out of an ironclad at midnight, thus throwing four or five hundred men into the sea to be choked by water, with scarcely the remotest chance of escape."

Those who have had much experience of gas warfare know that of all modern weapons it is the most humane, or, perhaps I should say, the least inhuman, as it causes the least amount of suffering, the smallest percentage of deaths, and by far the greatest percentage of complete recoveries. Proof of this may be obtained from the official medical histories issued by the various combatants in the great war and from standard works on gas and chemical warfare.

In 1937 the Representative Body of the British Medical Association passed the following resolution:

> "That this Meeting condemns unreservedly the use of poison gas in warfare as inhuman in its results and degrading to civilization, and relies upon the Council to do everything in its power with a view to securing the co-operation of the medical profession of all countries in order to prohibit the use of poison gas."

As no mention of high explosive shells or bombs was made, the use of these in modern warfare must be considered legitimate and humane. Those who were responsible must have been ignorant of the authoritative sources of information I have given. Perhaps they preferred the work of H. G. Wells. In his book *The Shape of Things to Come* there is the following description of gas warfare:

> "The tortures of gas were already many and various, and most of the mixtures then used left tormenting weakness in the system for the rest of life." Further on he declares that "gas warfare ranks in horror with the story of judicial torture or the story of ritual cannibalism, but its inhumanity is more striking because of its nearness to our time."

In his *History of the Next Hundred Years* he describes, most incorrectly, the effects of mustard gas.

> "It is doubtful if any of those affected by it were ever completely cured. Its maximum effect was rapid torture and death; its minimum, prolonged misery and an abbreviated life."

After I had finished reading the B.M.A. resolution I read in the daily newspaper that in Cleveland, U.S.A., forty constables dispersed with tear gas 600 strike pickets and their supporters! In France, as early as 1912, lacrimatory grenades had been used by the military in civil disturbances, and Prentiss, in his great work *Chemicals in War,* very pertinently points out:

> "No Government can be open to criticism for using against an invading army weapons already employed against its own unruly nationals" (p. 688).

Legitimate Gas Warfare

Few people realize that, with what might be termed the legitimate weapons of modern warfare in which explosives are used, many casualties from gas poisoning occur. During the great war thousands of casualties from gas poisoning were caused by shells, trench mortars, bombs, and aerial torpedoes bursting in deep trenches, dug-outs, cellars, concrete structures, and enclosed places, as well as in ships. Casualties from gas poisoning also occurred from mobile charges used to destroy dug-out systems, from bombs bursting in houses and flooding basements with gas, from the bursting of gas mains and pipes, and from many other causes.

Carbon monoxide was the most dangerous gas encountered in military mining. After a mine was exploded the galleries were filled with gas. In some cases this welled up the shafts and flooded the surrounding trenches, poisoning the occupants. Gas poisoning occurred in gun pits, in closed machine-gun emplacements, owing to the blow back, in tanks from leakage of exhaust, and from the use of coke braziers in cellars, dug-outs, and other confined places. As the official *Medical History of the War* properly states, in all these cases

> "the primary object for which the explosive was employed was its destructive effect, and it was to chance rather than to design that one must attribute the deadly effects of the fumes."

When the first Hague Conference was discussing the employment of projectiles, the sole use of which is the diffusion of asphyxiating or deleterious gases, it was pointed out that, when H.E. shells detonated, poisonous gases were generated which might cause death in confined areas. After discussion the Conference ruled that *if the splinter effect of a shell was greater than its noxious-gas effect, it would be regarded as a legitimate weapon, but if the gas effect were greater it should be banned.* That is to say, that allowance was made for the gases which are necessarily produced by high explosive shells. Gas was forbidden, but the most cruel and devastating of modern weapons, H.E. shells and bombs, received the sanction of the Conference. Prentiss very properly points out that the question of what projectiles were permissible within the meaning of the first Hague Conference was never actually put to the test, because, when gas warfare did begin on a big scale, it was not by projectile but by drift gas from cylinders.

Those who have extensive knowledge of the use of gas in warfare are greatly relieved that those in authority have recovered from their obsession regarding the importance of gas attacks from the air. They have now come into line with other countries which regard protection against H.E. bombs as of major, that against gas as of minor, importance. It is therefore much more important to study the use and effects of high explosives than those of gas poisoning, just as it is more important to provide splinter-proof shelters than gas-proof rooms.

High Explosives

In connexion with defence against aerial bombing certain important facts regarding explosives should be known to all doctors.

High explosives depend for their action upon the instability of the chemical equilibrium of their constituents. They consist of compounds of carbon, oxygen, nitrogen, and hydrogen so feebly combined that, when fired by combustion or detonation, new, simpler, and more stable compounds are formed. Once chemical action is started it proceeds with great velocity, and the explosive is immediately converted into gases with the evolution of heat. These gases, now occupying an enormously greater volume than the original substance, have powerful disintegrating properties. High explosives are very violent, detonating at the rate of several miles per second, many times greater than the most violent hurricane. In explosives used to propel bullets, shells, etc., the combustion is much slower. The violence and shattering effect of the explosive depend upon the velocity of detonation, which varies in different explosives, and also upon the amount of gas and heat generated. To effect detonation of high explosive a detonator is used, which in its action corresponds to a very violent and sharp blow accompanied by heat and flame.

Generally speaking, explosives contain an excess of oxygen, and, theoretically, should give rise to little carbon monoxide. But they vary much in this respect, and, in the conditions under which they are generally employed, produce considerable quantities of this gas. Shells give rise to less carbon monoxide than bombs or mobile charges. In all of these, if from any cause—deterioration of explosive, insufficient detonators, etc.—the wave of detonation dies out, and a slower form of combustion results, incomplete or partial detonation is said to have taken place. In this event the products of combustion are altered, much more carbon monoxide and, in addition, nitrous fumes being formed.

When a high explosive is ignited it burns at the rate of a few feet per second. During the war explosive salved from the enemy and from mines which could not be used was laid out in long lines and destroyed in this way. The products of combustion are quite different from those of explosion or detonation, very large quantities of carbon monoxide and nitrous fumes being formed. Such accidents occurred in the Navy during the war; and, in gold mining on the Rand, several accidents, where stores of explosive underground were accidentally set on fire, have been reported.

Notwithstanding the colossal scale on which explosives were used during the war, no epoch-making discoveries were made, and none have been made since. Nitroglycerine, which was discovered in 1846, still remains the most powerful high explosive. The large number of new explosives used during the war, and others which have appeared since, are merely new mixtures of substances which have been used for many years, some the natural outcome of shortage of certain materials. All the Powers at war, with the exception of Germany, used practically the same types of explosives. The Germans during the latter months of the war used liquid air very extensively as an explosive for demolition work, and for blasting operations in making dug-outs and tunnels. They were also the first to use liquid oxygen for supplying oxygen to airmen at high altitudes.

Very valuable information regarding explosives was gained from the extensive mining operations which were carried out on the Western Front. Never before had explosives been used on such a huge scale. The fact that in 1916 the enemy fired 700 mines and the British nearly 750 will convey some idea of the intensity of mine warfare. For a considerable period 30,000 men were engaged in active mining and in making underground protection for the troops.

It is the same in connexion with chemical warfare as with explosives, for to-day, twenty-four years after the start of this type of warfare, the two most effective gases belong to the phosgene and mustard gas groups. It is necessary to insist that the deadliest gases cannot be used in aerial warfare.

Most people have a very vague knowledge of explosives; this probably explains their easy belief in fantastic stories of the discovery of wonderful explosives of extraordinary power, tales of which are so often circulated by the Press. One recalls the report circulated soon after America entered the war, of a new American explosive, a tablespoonful of which would uproot St. Paul's. After the battle of Messines, when nineteen huge mines containing tons of high explosive were blown, it was amusing to read the statement of one famous correspondent that one pound of ammonal—the explosive used—could blow the

Mansion House to pieces. Tales of a similar kind have appeared at regular intervals in recent years, indeed they are a striking feature of the Secret Service and detective novels so widely read.

Liquid Oxygen and Liquid Air as High Explosives

A few months ago several newspapers harrowed the feelings of their readers by describing the devastating effects of a new bomb which had come into the possession of the Germans and which had been used in Spain. The high explosive in this bomb was liquid oxygen. It was half the weight of other bombs, and its explosive energy was said to be many times greater. What are the facts? This explosive has been in use for many years. It was first used on an extensive scale in the making of the Simplon Tunnel, where operations had been seriously affected and delayed by the dangerous contamination of the atmosphere from blasting by nitro-glycerine explosives. It was found safe to handle, powerful in action, and, except under most exceptional circumstances, did not produce poisonous fumes. Liquid air plant was installed and liquid air was used on a large scale to improve ventilation. After a short trial owing to practical difficulties its use was abandoned.

For a few years before the war the Germans had been using liquid air as an explosive in mining and quarrying. In the later years of the war Germany had available abundant supplies of liquid air from the manufacture of nitrogen, and great efforts were made to render it more practical and efficient. In 1917 and 1918 they used it for blasting in connexion with the construction of mine galleries, dug-outs, etc., and for carrying out demolitions. Towards the end of 1917 I took part in an investigation into its use as an explosive. Most valuable information was obtained from a South African mining engineer, who had a very large experience of blasting with this explosive. Engineers on the Rand have had many bitter experiences of the fouling of the atmosphere underground by high explosives. As the death rate from this among native labour was very high, strict precautions were taken, and in many mines compressed air and liquid air were in constant use to purify the air. The following were the principal reasons for abandoning its use as an explosive on the Rand. The same reasons prevented its adoption by the British during the war.

One great drawback to liquid air as an explosive, even when the cartridges were charged *in situ*, is its variability, the explosive power of the charge depending upon the proportion of oxygen in the cartridge, which necessarily varies from moment to moment. It is therefore less reliable, less efficient, and its results less easily controlled than other high explosives. Another important point is that, although weight for weight liquid air is more powerful than gelignite and other explosives—in other words its explosive energy is greater—with the type of cartridge used, bulk for bulk, it is less powerful. As a result the diameter of the drill-hole has to be twice that required for gelignite, etc. This was a serious drawback to its employment in mining. I understand that Woolwich Arsenal turned it down as useless for propellant work and for bombs.

Inflammable and Explosive Gases from Detonation of High Explosive in Bombing, etc.

The gases from the detonation of a high explosive vary in quantity and in composition according to the quality of the explosive used and also to other conditions. Those generally found are hydrogen, carbon monoxide, and methane (CH_4), all of which are combustible, and, when present in the proper proportion, explosive. Anything which prevents the carbon in the explosive being converted into CO_2 and the hydrogen H_2O will result in large quantities of H, CO, and CH_4 being formed. This will happen when there is imperfect detonation of part of the charge. Methane is never formed at the time of explosion, but results from the action of hydrogen on the oxides of carbon as the gas cools down. The greater the amount of hydrogen formed the greater will be the proportion of methane.

Explosives containing T.N.T. give rise to considerable quantities of hydrogen and methane. When any of the ammonium nitrate group of explosives are detonated in the open—for example, mobile charges, bombs, etc.—more CO, H, and CH_4 are found than when the explosive is detonated after being tamped. In some of the secondary explosions which I investigated during the war all these gases were present, but in others there was so little CO that canaries exposed to the atmosphere were unaffected.

The tendency of the gases to explode will depend on certain factors: (1) The amount of gas present—the larger the bomb the greater the volume of gas; (2) composition of gases; (3) velocity and density, pressure and concentration, of the gas. The greater these are the greater will be the liability to explode. Where gas is present in insufficient volume or in unexplosive percentage, and is ignited, the flame becomes spent.

The damage done to tunnels or dug-outs systems by the explosion of gases from detonation of high explosive is generally limited to a small area, and will depend upon the force of the explosion, much greater where the tunnels and galleries are narrow, much smaller when they are large. Even when explosives are used on a comparatively small scale in blasting enough gas may be given off to cause an explosion. The following is an example:

> In making a deep dug-out in very hard chalk, cheddite was used for blasting. Of the four shots fired two failed to detonate, one detonated imperfectly, and one completely. After twenty minutes had elapsed the men returned to the face to examine the effects and an explosion occurred. Inquiry subsequently showed that in this case the explosive used had been stored for a long time, with consequent deterioration.

During the war attention was first directed to the explosibility of gases formed from the detonation of high explosives. In 1916 a tunnelling company suffered considerable casualties, the officer commanding, another officer, and sixteen other ranks being killed. As this conveys a very good lesson of one of the great dangers of military mining, and *an entirely unknown danger of bombing*, I shall give a short description of what occurred. *Until this disaster was investigated the danger of carrying a naked light into galleries in which gas was known to be present was not appreciated.*

> The enemy exploded a camouflet—that is, a mine which did not break the surface or crater. The explosion was not intense and damage done to one gallery was small. It is probable that the mine had been charged for some time and the explosive had deteriorated. At the time four officers and a considerable number of men were in the galleries. There was an order that as soon as an explosion occurred everyone must leave the mine; an attempt was made to carry this out, but before this could be effected a secondary explosion occurred. The two officers near the site of the explosion were killed by the force of the explosion, both showing extensive burns; the sixteen men, who were at a considerable distance from the point of explosion, were killed by carbon monoxide. The mine rescue men were able to save a large number of the men. As a result of this an order was issued that no naked lights were to be used in the galleries till these were proved clear of gas. Electric lights were always to be employed when gas was known to be present.

Bombs and aerial torpedoes on detonation give rise to large quantities of gas, the CO content of which will be greatly increased if part of the charge is imperfectly detonated. Hence when they incompletely detonate in houses, the occupants of the cellars and basements are not only exposed to the dangers of gas poisoning against which the gas mask offers no protection, but they run the risk of gas explosions and fires. During the war in air raids on cities and towns and villages serious gas explosions and fires occurred and many lost their lives.

The gas thus produced may be ignited by the great heat resulting from the detonation of the bomb, or by incendiary bombs, or by the presence of a naked light. As bombs penetrate deeply before detonating gas may be given off from the ground slowly, and very gradually collect in cellars and basements, to be fired by someone approaching with a naked light; sometimes it may be hours after the bombardment has ceased. In other cases gas has found its way into cellars at a distance from the exploding bomb by passing through fissures that have been caused by the explosion. Serious gas explosions and fires were also caused by the ignition of illuminant gas that had escaped from pipes smashed by the explosion. These explosions may occur during salvage work among the debris, when pockets of gas may be fired.

It is an obvious precaution to make use of electric torches during all operations where gas is suspected, and, after an air raid, never to enter a cellar with a naked light.

THE STRETCHER PROBLEM

BY

L. CROME, B.Com., L.R.C.P. & S.Ed.

Formerly Chief Medical Officer, XVth Spanish Army Corps

No single item in the equipment of the medical services in time of war is more important than the stretcher. In the Spanish War, as a result of extensive experience, one type was universally adopted for use in the armed services and in the civilian casualty organizations. This stretcher was employed in the field for the primary transport of casualties from the line of fire to the dressing stations. The same stretcher was carried in all ambulances, and was used in the waiting rooms of field and base hospitals and in all medical units connected with A.R.P.

At present there are two main types of stretcher in existence in England. One is the standard R.A.M.C. stretcher and the other is the type recommended by the Ministry of Health for A.R.P. purposes. The fact that the Ministry of Health has recommended a stretcher entirely different from that used by the R.A.M.C. points to the conclusion that the latter was not considered satisfactory; while the fact that the R.A.M.C. has not adopted, and is unlikely to adopt, the stretcher recommended by the Ministry of Health must imply that neither of the two types is entirely adequate. Before describing the stretcher used in Spain it is necessary to point out that stretchers serve three main and two subsidiary purposes. They are used (1) to carry wounded from the field to the ambulance base; (2) in motor vehicles and trains for the transport of wounded to and from hospitals; and (3) in the waiting rooms of dressing stations and hospitals for the interim accommodation and treatment of patients before operation or hospitalization. The secondary uses of stretchers are (*a*) as sleeping accommodation for medical personnel; and (*b*) for the erection of huts, shelters, covers, and camouflage in circumstances where no other building material is at hand.

General Specification

Stretchers must have definite qualities, which will now be stated in their approximate order of importance.

1. Stretchers must be as light as is compatible with serviceability.

2. Stretchers must be comfortable. At times patients will have to lie on them for twenty-four hours or more.

3. Stretchers must be robust; they will have to stand up to the hardest wear.

4. After gas attacks stretchers may have to be decontaminated. It is essential to use material which will stand decontamination.

5. Although not much can be done in the way of postural treatment during transport, it is helpful to have a stretcher capable of holding some part of the patient's body in a position of elevation. This is especially important in cases of cranial or thoracic injury.

6. Stretchers must have sufficient clearance to prevent the patient from touching the ground. If a patient is at a sufficient distance from the ground, treatment, such as injections, bandaging, blood transfusion, is considerably easier.

7. Stretchers must be used in motor vehicles, not all of which have been constructed as ambulances. The minimum of structural alteration of the vehicle itself should be necessary before it is adapted to carry stretchers.

8. Stretchers must have suitable attachments for the application of essential splints, such as the Thomas splint.

9. While not in use for the transport of casualties the stretchers will have to be carried by stretcher-bearers from one place to another. It is necessary to make this work as easy as possible. At times only one man will be available to carry such a stretcher.

Need for Standardization

Two essential considerations in the transport of casualties are the prevention of shock and the prevention of further local injury at the site of the lesion. All extra handling of the patient, such as is necessary for the changing of stretchers, increases the danger of shock and of further injury. The ideal to aim at is, therefore, complete and uninterrupted transport of the casualty on one stretcher. At each break in the evacuation journey the loaded stretcher should be exchanged for an empty one, the latter being returned to the previous point by the returning stretcher-bearers or ambulance. Thus the patient will be spared the pain, discomfort, and danger of being moved from one stretcher to another, and much time will be saved in the process of evacuation. Ambulances will be able to return immediately after depositing their casualties and receiving in exchange an equal number of empty stretchers with the corresponding number of blankets. Such a system of relay evacuation is only possible if the same type of stretcher is used throughout the evacuation line. The needs of the armed services and of the civilian population are identical in respect of stretchers, and there is no reason why the same type of stretcher should not be used throughout the country.

If a "universal" type of stretcher is necessary from the functional point of view its standardization is essential from the point of view of production, maintenance, and replacement. The stretcher requirements of the armed forces may be calculated from the presumed ratio of one stretcher to thirty men. For the civilian population the ratio is more variable, but an anticipated figure of 500,000 stretchers at the beginning of the war, going up to 750,000 during the first year, is not an exaggeration. The problem of production on this scale and continuous replacement can only be satisfactorily solved by complete standardization and the timely preparation of raw materials necessary in the construction of these stretchers. It is also desirable that if one of the component parts of a stretcher is irreparably damaged or lost it should be capable of being replaced by another identical part without the necessity for discarding the entire stretcher.

Storage space must also be considered. Stretchers must be produced in peace time and stored, and they must be delivered in such a way that the minimum space is required for their transport and storage. Finally, cost can only be brought down to a minimum if the stretchers are standardized on a mass production basis.

The Spanish Stretcher

The Spanish stretcher consists of five parts which can be readily assembled: (1) two horizontal wooden poles; (2) iron head-piece; (3) iron foot-piece; (4) a double layer of canvas fastened with leather straps in front of the head-piece; and (5) two shoulder-slings made of stout leather with loops for the handles of the stretcher. When assembled, the stretcher is carried by two bearers, each wearing a shoulder-sling in such a way that the weight of the stretcher is secured by these slings even if the hand grip should fail (Fig. 1). Dismantled head- and foot-pieces can be rolled into the canvas and carried on the shoulders of one of the stretcher-bearers, being secured by the shoulder-slings. If necessary, the same stretcher-bearer can also carry the poles (Fig. 2), but it is usual for the poles to be left to the second stretcher-bearer.

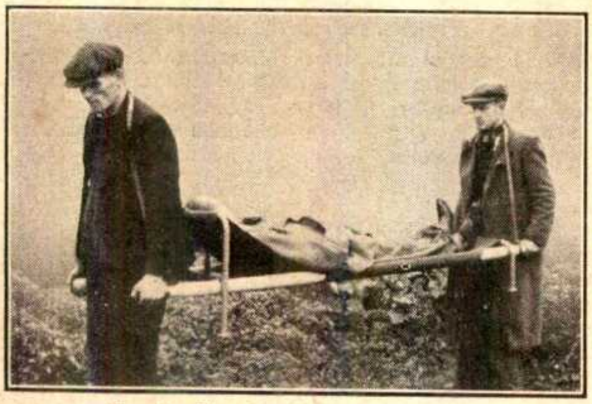

Fig 1.—The Spanish stretcher in use.

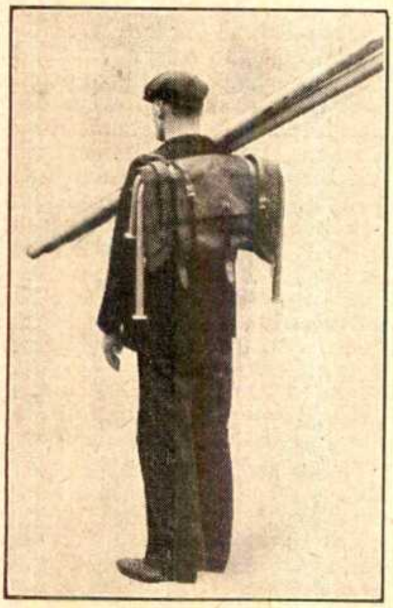

Fig. 2.—The Spanish stretcher dismantled.

The fittings necessary for the reception of the stretcher in a motor vehicle can also be used for stretchers which are not of the type described (Fig. 3). These fittings are inexpensive and easy to manufacture, and can be fitted in any closed van without structural alteration. Each fitting has two swivels which enable it to be swung flat against the side of the ambulance, leaving space free for sitting patients if this is required. Though it serves as a spring, the fitting is extremely strong. During the whole of the Spanish War it was unknown for any of them to give way. Moreover, it has a very small surface and is therefore seldom damaged by fragments of bombs or shells.

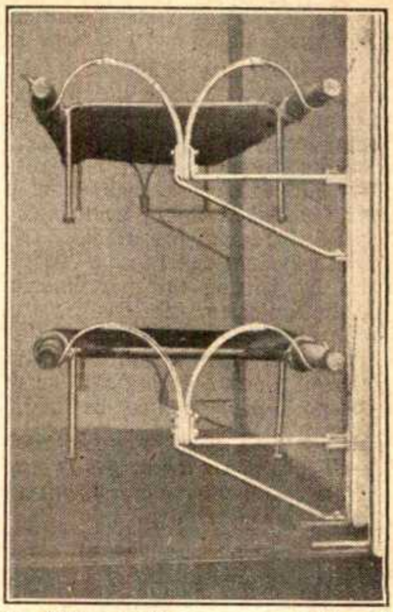

Fig. 3.—The fittings used to convert an ordinary light van for use as an ambulance.

Conclusion

It is suggested that the type of stretcher described can be put to all uses in war time. It meets all the requirements for such stretchers and is easily standardized.

By reversing the position of the patient on the stretcher the upper horizontal bar of the head-piece may be used for attachment of a Thomas's splint. The empty triangular space formed by the upper and lower layers of the canvas at the attachment to the head-piece may be used for carrying the patients' loose belongings.

All the component parts of the stretcher, including the canvas, are detachable and can easily be cleaned, washed, disinfected, and decontaminated.

The incline formed by the upper layer of the canvas allows for postural treatment. The complete stretcher weighs 25 lb.

While I have not attempted to balance the advantages and disadvantages of the suggested stretcher against those used by the R.A.M.C. or recommended by the Ministry of Health, its relative merits will be readily appreciated by all who are familiar with the problem.

I wish to express my gratitude to Messrs. N. A. Bronsten and Co. Ltd. for their good offices in preparing the demonstration model of the stretcher described above and allowing me to reproduce the photographs.

Photodynamic Activity in Carcinogenic Hydrocarbons.—Exposure to extreme dilutions of either of four carcinogenic hydrocarbons sensitizes cultures of Paramoecium to ultraviolet light. Other substances having this photodynamic action (eosin, acriflavine, etc.) are less potent and unaffected by light conditions during contact, whereas carcinogenic hydrocarbons sensitize much more effectively in the dark. These observations, apart from their wider theoretical interest, disclose a method for the biological assay of small quantities of carcinogenic hydrocarbons.—Comparison of Photodynamic Activity of Some Carcinogenic with Non-Carcinogenic Compounds. I. Doniach.—*Brit. J. exp. Path.* June 1939, **20**, 227.

INCOME TAX

Diminution in Earned Income

In his Budget speech the Chancellor of the Exchequer made it clear that he recognized that while all income-taxpayers would have to make sacrifices to meet the increased demands under the new Finance Act, the higher rates of duty would bear with particular severity on those whose incomes were falling, and especially where the income was "earned." That is, of course, the inevitable consequence of the system of assessing income for one year on the basis of the profits of the previous year. To pay at an increased rate of tax on, say, £1,000 is bad enough if the income is stable, but it is harder still to find the tax if in the meantime the income has fallen to, say, £750. Accordingly, Section XI of the Finance (No. 2) Act, 1939, provides some measure of relief to taxpayers whose incomes come within a carefully defined class. The national circumstances of the present year will affect individual incomes to a very great extent, and medical practitioners will be by no means exempt from the general fluctuations. For that reason it may be convenient to put on record at the earliest opportunity the main features of this form of relief. In the first place the relief applies to "individuals," and not, for instance, to a partnership as such; in the second place the fall in income must be "owing to circumstances directly or indirectly connected with the war"; and, thirdly, the relief applies only to "earned income." In order to invoke the benefit of the section a claim for 1939–40 must be made by April 5, 1941, and the claimant must be able to show that his actual earned income for 1939–40 is not more than four-fifths of the amount at which it is assessed. If, therefore, the earned income has fallen from £1,000 in 1938–9 to £750 in 1939–40, the assessment on £1,000 for 1939–40 (on the basis of the previous year's earnings) can be reduced to the actual earnings of that year—that is, to £750.

There is one corollary to the relief which should not be overlooked. If the taxpayer elects to have the 1939–40 assessment adjusted in that manner then the Revenue authorities can require an adjustment of 1938–9 to the actual earnings of that year—the reason being that otherwise a "bumper" profit of 1938–9 might escape the Revenue net. There will, of course, be a number of cases where the fall is heavy but less than one-fifth; and it would obviously be unfair if a reduction of 20 per cent. gave full relief and a reduction of, say, 19 per cent. obtained no relief at all. To meet that point some elasticity has been given to the limit by providing that, in effect, a taxpayer can, so to speak, forfeit to the Revenue the excess over four-fifths and then obtain the relief he would receive if his earned income had in fact been reduced to four-fifths of his assessed income.

One further point should be mentioned. While the section is not explicit on the point it appears to be drawn in such a way as to require aggregation of the earned income for the calculation of the ratio of diminution. For instance, suppose a single-handed practitioner whose earnings in 1938–9 (and therefore his assessment for 1939–40) were £1,000 joins the Forces, with the result that for 1939–40 his practice earnings fall, partly perhaps owing to the employment of a locumtenent, to, say, £700, but on the other hand he receives assessable military pay to the extent of £300, then his assessed earned income is (£1,000 + £300 =) £1,300, and his actual income is (£700 + £300 =) £1,000, and as £1,000 is less than four-fifths of £1,300 he is entitled to have the assessment on his practice reduced from £1,000 to £700. Further, if the practice earnings were £750 instead of £700, so that the actual earned income became £1,050 as compared with four-fifths of the assessed earned income—that is, with four-fifths of £1,300 = £1,040—then he could have the "actual" basis applied, but would have the relief restricted by the £10 he would be required to forego to bring himself within the limit of four-fifths.

It will be realized that the provision is one of considerable complexity, but it will be of real benefit in many cases, and is therefore one which should be borne in mind whenever the application of the previous year's basis to the assessment of earnings inflicts substantial hardship.

A STUDENTS' REGISTER

An accurate but incomplete register of medical and dental students who have been admitted to the schools during the last academical year has lately been issued by the authority of the General Medical Council under the new provisions for students' registration, which came into force in September, 1938. The volume consists of an alphabetical list of the students admitted during the year, with the date of birth, the date and kind of preliminary and additional examinations, the school at which medical studies have commenced, and the date of registration. The number of medical students whose names have been returned to the Council by the authorities of the schools is 1,735, but another 400 or 500 must be added because, for some unexplained reason, returns are not forthcoming for several schools, including Liverpool, Aberdeen, St. Andrews, Queen's University, Belfast, and University College, Dublin.

The various preliminary examinations in general education by virtue of which the students have been admitted to the schools of medicine and of dentistry number nearly seventy. Most of them are held by universities, a few by public authorities, such as the Scottish Education Department and the Central Welsh Board, or by chartered bodies such as the College of Preceptors. The examination which has brought the largest number of medical students on to the register is the London Matriculation (188), followed closely by that of the Scottish Universities Entrance Board (178), the School (or Leaving) Certificate Examination of the Oxford and Cambridge Schools' Examination Board (173), the Cambridge "Previous" Examination (153), and the London General Schools (140). Of the twenty-four additional examinations taken the highest number of medical students (507) came through the University of London; the next highest through the University of Edinburgh (202). Examinations held abroad gave thirty-eight medical students and the same number of dental students to the register, but whereas most of these medical students entered by way of universities in the British Empire, most of the dental students were Continental exiles who had taken their degree in medicine many years ago, chiefly in Vienna.

Of the medical schools to which the students have been admitted, those of the University of London have taken 506, King's College and University College each taking over 100; the University of Cambridge has taken 159, that of Oxford 89, that of Durham 76, while Leeds and the Victoria University, Manchester, have each taken 67. The students who have started at Edinburgh number 202; Glasgow can show only half that total. The number of women who have entered the study of medicine during the past year is 284, or just over 16 per cent. of the total entry. Medicine attracts a larger proportion of women than does dentistry, for of the 316 dental students only 32 are women, or 10 per cent. The oldest student to enter medicine is a woman; she was born in 1893, passed the London Matriculation examination in 1922, and is now beginning medical study at the London School of Medicine for Women. She has half a dozen men colleagues, however, who are taking up medicine when over the age of forty. The year of birth of the great majority of students, medical and dental, is 1919 or 1920. A few—140 medical students—were born in 1921.

No one could have foreseen at the time this register was compiled that the students whose names it contains would now be so widely dispersed, receiving their training in places and under conditions so unexpected, yet their unusual experience may be of value. Glancing over these arid lists of names one cannot help wondering whether here and there one of them may be on the tongues of all men forty or fifty years hence.

Nova et Vetera

AN EARLY EXPERIMENTAL LOBECTOMY

Mr. R. T. Gunther, keeper of the Old Ashmolean Museum at Oxford, has recently published the twelfth volume of *Early Science in Oxford*. It deals with Dr. Robert Plot and the correspondence of the Philosophical Society of Oxford with the Royal Society in London and the Philosophical Society in Dublin. The letters which passed between the Oxford and the Dublin Societies are of especial interest. Here is one from Dublin dated November 10, 1684.

"Dr. Mullen gave an account of the following experiment: A vintner in this town being troubled with a consumption, complained much of a trouble in the left side of his thorax, and would often with some confidence and persuasion assert that he was sure he should do well enough could the thorax be opened and a certain piece of his lungs be cut out with impunity. But this desperate remedy was not hearkened to by anyone: so the sick man died. Notwithstanding, Dr. Mullen resolved to try the experiment on a dog, and opening its thorax he cut off from one lobe of the lungs a piece three inches long and two broad, and making a ligature to hinder the effusion of blood he closed the wound. The dog recovered perfectly well and showed no manner of want of what he had lost. About six months afterwards the doctor hanged the dog, and opening it found the end of the lobe, where the wound was made, firmly united to the intercostal muscles where the thorax was opened, and the thread that made the ligature had vanished and was supposed to have been discharged through the wound in the chest."

Dr. Allen Mullen, who records the experiment, was a brilliant young anatomist of North Irish extraction who is said to have come to a bad end. He graduated from the Dublin University, taking his Arts degree in 1676 and his M.D. in 1684. He was elected F.R.S. on July 18, 1683, and became a member of the newly formed Dublin Philosophical Society in the following year. He left Dublin for London on account of some trouble with a lady, went to Barbados, drank too much, and died there in 1690.

D'A. P.

AMERICAN ASSOCIATION OF THE HISTORY OF MEDICINE

The American Association of the History of Medicine, which, alas! possesses no congener on this side of the Atlantic, held its fifteenth annual meeting at Atlantic City, New Jersey. With a view to increasing its usefulness and to stimulating research, study, and interest in medical history in North America, the Association last year adopted a new constitution and by-laws and chose as its official organ the *Bulletin of the Institute of the History of Medicine of the Johns Hopkins University*, now known as the *Bulletin of the History of Medicine*. The meeting was well arranged, due space being given to both new historical material and to a critical evaluation of existing knowledge, and the papers, which were published in the July number of the *Bulletin*, were appetizingly short. Among the material presented was "The Old Age of King Lear" by Professor John W. Draper, "Nursing Cans" by Dr. Howard Dittrick, "Clinical Teaching in America with Some Remarks on Early Medical Schools" by Professor David Riesman, "Idealogical Basis of Discoveries" by Dr. Iago Galdston of the New York Academy of Medicine, and "Provision for the Sick Poor in Colonial Times" by Mr. Albert Deutsch. In an account, full of colour and scholarship, of "Occupational Diseases of English Seamen during the Seventeenth and Eighteenth Centuries," Dr. George Rosen of Brooklyn dealt with such maladies as scurvy, typhus, typhoid, dysentery, relapsing fever, and yellow fever. One of the most challenging papers, the presentation of which was a continuous delight, was "The Place of the Amateur in the Writing of Medical History" by Mr. W. B. McDaniel, Librarian of the College of Physicians of Philadelphia. At the Council meeting the delegates of the constituent societies read their reports, Dr. Victor Robinson representing the recently launched New York Society for Medical History, and at the business meeting Dr. Esmond R. Long was elected President, Dr. Edward B. Krumbhaar, who had founded and steered the Association through its infant years, Honorary President, and Drs. Harvey Cushing, Arnold C. Klebs, Rudolph Matas, and Charles W. Burr Honorary Members. After the dinner the retiring President, Dr. Walter R. Steiner, gave an address entitled "Some of Louis's Distinguished American Pupils," and Dr. William G. Leaman of Philadelphia, through a fascinating film, showed how medical history may be introduced into clinical teaching. The Association's secretary, Professor Henry E. Sigerist, is to be congratulated on the success of this meeting, which was very largely due to his foresight, imagination, and tireless energy.

HISTORY OF MEDICAL SOCIETIES

The work on *British Medical Societies*, edited by Sir D'Arcy Power, who has written the preface and the account of the Abernethian Society, consists of thirty-four articles by various writers which originally appeared in the *Medical Press and Circular* and have been now republished with or without additions.[1] Of the thirty-four societies, one (Society of Apothecaries) was founded in the seventeenth century, seven in the eighteenth, seventeen in the nineteenth, and nine in the twentieth. But for the amalgamation in 1907 of seventeen societies in the Royal Society of Medicine, whose history is related by a former president, Dr. T. Watts Eden, the list might have been considerably longer. The topographical distribution of the societies is as follows: London, 21; provinces, 6; Wales, 1; Scotland, 4; and Ireland, 2.

Among the earliest medical societies were those founded by medical schools, such as the Royal Medical Society of Edinburgh (1737), Guy's Hospital Physical Society (1771), and the Abernethian Society of St. Bartholomew's Hospital (1795). The Listerian Society of King's College Hospital received its present name in 1912, having previously been known as the Hospital Medical Society since its foundation in 1833.

The majority of the societies deal with medicine in the widest sense of the term, and the only specialist societies described are the Ophthalmological Society of the United Kingdom, founded in 1880, the Anatomical Society of Great Britain and Ireland (1887), the Medico-Legal Society (1901), the Medical Section of the British Psychological Society (1901), the Pathological Society of Great Britain and Ireland (1906), the Royal Society of Tropical Medicine and Hygiene (1907), the Research Defence Society (1908), and the Association of Surgeons of Great Britain and Ireland (1920).

Many papers which have since become classical were first read before these societies, such as John Hunter's paper on ligature of the femoral artery and Jenner's on vaccination before the Guy's Physical Society in 1802; Paget's paper on *Trichina spiralis* before the Abernethian Society when he was a student in 1835; and Sir William MacEwen's paper on cerebral abscess before the Royal Medico-Chirurgical Society of Glasgow in 1887. Mention must, of course, be made of the publications of the largest medical society in the British Empire, whose history is written by Sir Henry Brackenbury—namely, the British Medical Association—which has issued the results of various collective investigations of urgent medical interest.

The book contains numerous illustrations, including portraits, meeting-places of the societies, and presidential badges.

ENGLAND AND WALES

London County Medical Officer of Health: Retirement and New Appointment

At its meeting on October 17 the retirement of Sir Frederick Menzies, medical officer of health, was reported to the London County Council, and the Council adopted a resolution placing on record its high appreciation of the services Sir Frederick Menzies has rendered. The Emergency Committee stated that his retirement would deprive the Council of the services of an officer in whom it had justifiably placed the highest confidence. "The strength and graciousness of his character and personality have won the respect and esteem of members of the Council and of the members of his staff, both at the central office and at the hospitals." On the question of superannuation, it was stated that Sir Frederick Menzies became a full-time officer of the Council at the age of 35 years. A regulation of the Council provides that in considering the grant of special retiring allowances to officers who enter the service of the Council at the age of 30 or upwards due weight shall be given to the fact of such entry, coupled with the possession of special qualifications not usually to be obtained within the service. The Council decided to add five years to his pensionable service, the effect being that while the lump sum (£3,000) payable to him from the superannuation and provident fund remains the same, his pension of £1,056 a year from that fund will be supplemented by a separate amount, payable out of the county fund, to bring the total to £1,306 a year.

The present deputy medical officer of health, Dr. W. Allen Daley, was appointed to succeed Sir Frederick Menzies as from November 2, the date of his retirement, his salary to be £2,750, rising after one year to £3,000 a year. Dr. Daley, who is 52 years of age, had a wide experience in the provinces, culminating in his appointment as medical officer of health and school medical officer of the city of Hull. In 1929 he became a principal medical officer in the public health department of the L.C.C., and was placed in charge of the general public health division. Subsequently the scope of his responsibilities was widened to include the oversight of staffing and other matters connected with the hospitals service. He acted as medical officer of health for a period of six months in 1932 during the absence on sick leave of Sir Frederick Menzies. He was appointed deputy medical officer of health and deputy school medical officer in November, 1938, and has had wide responsibilities as second officer of the department. Dr. Daley is also a representative of the Minister of Health on the Central Midwives Board, vice-chairman of the Central Council for Health Education, and examiner in public health to the University of London.

Cancer Research in Yorkshire

The reports and accounts of the Yorkshire Council of the British Empire Cancer Campaign, 1938–9, include the report of the department of experimental pathology and cancer research, University of Leeds, and of research work on cancer at the Field Laboratory, University of Sheffield. An investigation is in progress on the mechanism of carcinogenesis by the dye *p*-dimethylaminoazobenzene, alternatively known as dimethyl-yellow or as butter yellow, a substance which, as was shown a few years ago by Kinosita and other Japanese workers, induces malignant disease of the liver, hepatomata, and chalangiomata when given orally or by injection to rats and mice. In the present study rats are killed at intervals during a course of feeding, and it appears that the formation of liver cancer is preceded by cirrhosis. This experimental cirrhosis bears a number of points of resemblance to the ordinary multilobular cirrhosis of human beings, considered by many observers to be a precancerous condition, but it also shows a notable difference—the absence of ascites. It is suggested, however, that since the tumours appear to arise at a comparatively early stage in the experimental process the absence of ascites may be attributable to the death of the animal before there is time for the condition to appear. A point of interest is that tumours can arise at a period when the cirrhosis is not as yet irreversible, for in animals killed some time after the administration of the dye has been discontinued the tumour-free portions of the liver may have returned to a more or less normal condition. Further experiments deal with the action of large single doses of dimethyl-yellow upon the livers of animals; also with the rate of absorption, which has been found to be very rapid. The rate of excretion of the dye is still under investigation.

AUSTRALIA

Queensland University Medical School

On August 11 the Hon. W. Forgan Smith, LL.D., Premier of Queensland, officially opened the Medical School of the University of Queensland at Brisbane. This is the final achievement in the campaign for the provision of facilities for medical education in the State. When in October, 1936, the Faculty of Medicine within the University of Queensland was inaugurated that function marked the successful issue of representations which began as long ago as the foundation of the University itself. The first proposals in 1913 were interrupted by the outbreak of war. In 1922 arrangements were made for anatomical demonstrations to be given to some of the dental students, who received two years' training at the dental school in George Street. In 1925, largely as the result of the work of a subcommittee of the Queensland Branch of the British Medical Association, a conference of delegates was called by the Home Secretary to discuss the subject. Two years later, with the co-operation of the Brisbane and South Coast Hospitals Board, a small school of anatomy for the teaching of dental students was established. In 1934 the activities of the anatomy school were transferred to a building given to the University for the purpose by the Freemasons of Queensland. In the following year a Faculty of Dentistry was established within the university and the Premier of Queensland appointed a select committee to report upon the practicability or otherwise of establishing a Faculty of Medicine and a Faculty of Veterinary Science within the University. The committee strongly advocated the institution of these faculties, and stated that the Faculty of Medicine should include particularly tropical medicine and public health as parts of routine medical education, and should be based upon recognition of the essential nature of the practical and clinical side of medicine. Meanwhile the College of Pharmacy was made available to the University for the purpose of physiology. With the establishment of schools of anatomy and physiology it became possible to provide medical courses for students of the second and of the third year. The next step was to provide further accommodation to include the departments of pathology, social and tropical medicine, and other clinical departments. The Government undertook the cost and decided to provide worthy buildings.

The new Medical School of the Queensland University occupies a commanding position at Herston on a site of over six acres adjoining the western boundary of the Children's Hospital and within a few minutes' walk of the Brisbane General Hospital. The building, in the Renaissance style, is three stories in height, and surmounted by a copper dome rising from a flat roof. If future extensions are required these can be added in the form of projecting wings at either end of the central block, which measures 222 feet in length. It is intended that fourth, fifth, and sixth year students shall receive in the Medical School the whole of their training in all branches of medical and surgical science and that the third year students shall receive their training in anatomy there, while first and second and the remainder of the third year work will be carried out at the present University, and later on at the new building in course of erection at St. Lucia.

Reports of Societies

THE PROFESSION OF SURGERY

Mr. Zachary Cope's Address

The annual address from the chair of the Medical Society of London was delivered on October 9 by Mr. V. ZACHARY COPE, the incoming president, whose subject was "The Profession of Surgery."

Mr. Cope began with the remark that during his own lifetime of fifty-eight years surgery had developed from an unscientific to a scientific profession which had strongly established itself among all civilized peoples and brought benefit to nearly all persons at some time in their lives. The advance of the surgical craft had been so rapid and its conquests so firmly consolidated that it was scarcely realized that the profession was a new one—new in outlook and achievement and new in its economic and social importance. The modern profession of surgery bore little or no resemblance to the surgery of sixty years ago. The young surgeon of to-day performed as a routine operations, undreamed of at that not very distant time, and from the economic point of view surgery had brought to the community health, happiness, and working power of a value beyond estimation.

In the modern sense surgery was impossible until the prevention of infection of wounds was demonstrated. Lister's first important publication on the use of antiseptics was made in 1867, while Lawson Tait's empirical but successful aseptic methods began just a little later. It was well known that the London surgeons were among the last to accept Lister's teaching, but it deserved to be recalled that it was at a meeting of the Medical Society of London that Lister obtained one of his first acknowledgments in the metropolis. That meeting was held on October 29, 1883, when he addressed the society on the operation for fracture of the patella. At the end of his address he was given a good reception, and in reply he was reported to have said: "Gentlemen, thank you most heartily for that cheer, for there was a time when such remarks proceeding from my friends met with a different reception." Sir George Turner in his reminiscences stated that Lister said of that cheer that it was the first he had had since he came to London five years before.

Great Periods of Surgery

The period between 1867 and 1881 was described by Mr. Cope as the gestation period of modern surgery; from 1881 to 1900 as the time of youth; from 1900 to 1918 as adolescence; and from 1918 until the present day as maturity. During the earliest of these periods the teaching of Lister was rapidly spreading through Germany, America, and finally England. Even before 1867 ovarian cysts had been successfully removed on several occasions, and colostomies had been performed by some surgeons, but before 1881 no appendix had been removed, no perforated ulcer had been successfully sutured, the surgery of the thyroid was unknown, the surgery of the spinal cord and brain, apart from depressed fracture, had not begun, and renal surgery had hardly been touched.

The period from 1881 to the end of the century saw great advances in all directions. The surgeons explored every type of disease which they thought might be relieved by the new surgery. The necessary process of trial and error was not always followed by successful results, but by 1900 the lines of modern surgery had been laid down, though not standardized. From then until the beginning of the great war the new surgery showed some of the symptoms of adolescence—for example, in the extremes of some operations then performed—but during this period there was an increasing standardization of well-recognized operations, and new fields were being opened up, though there was evident neglect of certain important sections of surgery which were apparently overshadowed by the development of surgery of the abdomen. This was particularly the case with the treatment of simple fractures, wounds, and orthopaedics generally. During the last war grim necessity forced surgeons to focus their attention on the treatment of wounds, fractures, and deformities, and one outcome was the rapid development of plastic and orthopaedic surgery.

To-day there was no part of the body which was immune from the attack of the surgeon, and no organ or viscus which had not at some time or other benefited from surgical intervention. The scope of surgery had widened to such an extent that it was an important factor in maintaining the health of the nation. In the year 1932—the last year for which he could get good statistics—over 150,000 operations were performed in the hospitals of London alone. At a conservative estimate this meant that half a million operations were performed annually in the country as a whole, and that more than one per cent. of the population underwent an operation in a year.

Supply of Surgeons

The necessary corollary followed that it was in the highest interests of the nation that there should be an adequate supply of thoroughly trained and experienced surgeons. Could it be said that such a supply was available? An affirmative answer could not be given with certainty. There was no doubt that surgeons at hospitals were worked harder than in past times if the number of operations were taken as a criterion At St. Mary's, his own hospital, sixty years ago there were ten operating surgeons, to-day there were fifteen, yet during those sixty years the number of operations had multiplied many times. In 1877 the number was 154, and in 1882, 613; by 1906 it had reached 1,632, and in 1938 this figure was more than doubled. These statistics showed the increased work which had been thrown upon the individual surgeon, but they did not necessarily prove a dearth of surgeons. Those in large cities might sometimes think that the profession was overcrowded, but it must be remembered that it was to large cities that talented and ambitious men naturally gravitated. A better opinion could perhaps be gathered by considering the number of surgeons who obtained the higher surgical qualifications. In England and Wales in 1880 there were 1,215 holders of the F.R.C.S.; in 1938 the Calendar of the Royal College gave 2,480, almost exactly double, this in a period during which surgical activity, as judged by operations only, had increased tenfold. Admittedly there were other high surgical qualifications besides this diploma, but there was no reason to suppose that the number of their possessors had increased to a greater extent than the roll of the Royal College. It must be concluded either that the country was over-supplied with surgeons in 1880 or that it was under-supplied at the present time. That the latter was more likely was suggested by the fact that many surgeons were attached to two, three, or four hospitals of considerable size.

Training of the Surgeon

Although modern surgery required a high degree of special training there was in this country no compulsion on the surgeon to undergo any special postgraduate course and no necessity for him to obtain any special diploma in surgery before starting to practise this difficult art. The only guarantees that intervened between the incompetent surgeon and the public were: (1) the discriminating judgment of hospital committees; (2) the discriminating judgment of his professional colleagues; and (3) the sense of responsibility of the surgeon himself. It was a testimony to the good sense of the profession that these guarantees seldom failed.

Mr. Cope proceeded to discuss the kind of training which the surgeon ordinarily received. Usually he began by holding the office of surgical registrar, though sometimes a man might gain a staff appointment after doing some special research work and without serving as registrar. Some entered the municipal service, where they got excellent experience with a varying amount of supervision. Nearly all the routes ensured that the surgeon gained experience under the supervision of senior men. Fortunately the instances were rare in which men who had not even held a house appointment went straight into practice and attempted major surgery. It must be admitted that the surgeon could not be standardized any more than the general practitioner, but it should be possible to ensure a greater minimum of knowledge and experience in everyone wishing to become a surgeon.

The responsibility of the profession to the public was such that adequate guarantees as to the sufficient training of anyone wishing to practise major surgery should be furnished. The American College of Surgeons had a scheme whereby everyone who wished to become a Fellow of the College was required to undergo a strict and extended apprenticeship after qualification. It was probably true that in none of the higher British surgical qualifications was supervised practical experience sufficiently insisted on as an essential preliminary for the candidate. Some qualifications indeed were open to the criticism that they seemed more in the nature of competitive examinations than tests designed to demonstrate a candidate's skill and experience of surgery.

In spite of the criticisms that might be made as to surgical training, the general level of surgery in this country was very high, and the position of the surgeon in the community was probably more respected than it had ever been owing to the great and often speedy benefits he brought to many patients. The surgeon had gained the confidence of his fellow citizens to such an extent that he was often expected to do the impossible. The public appeared to think that if only the surgeon would do something, good was sure to result. Some of the most difficult moments for the surgeon were those in which he felt it necssary to advise against operation when the relatives clamoured for something to be done.

Rewards of the Surgeon

The life of the surgeon was of absorbing interest, whether from a humanitarian or a scientific point of view, or from the point of view of that less praiseworthy but common desire to obtain benevolent power to control the destinies of other mortals. To no man was the destiny of human life so often delivered. As a judge he had not only to give the verdict but himself to carry out the sentence. His power of speedy diagnosis and decisive action in a crisis was of the greatest value. A famous physician-dramatist had said: "He is surrounded by respectful and even adoring acolytes, and he holds the power of life and death over helpless persons. If he is to avoid madness he must stand aside from the business from time to time and deride himself and his colleagues." Mr. Cope thought that it would be sufficient if each surgeon limited his derision to his own failings.

In some respects the surgeon of to-day was more isolated than his forerunner of fifty years ago. At the beginning of the modern era it was customary to have regular consultations between the members of the staff of the large hospitals. This practice had fallen into disuse. Each member of the staff worked on his own and might seldom see his colleagues. There were welcome signs, however, that a system of co-operation might soon be general. The advantages of the group system were becoming recognized. Here the diagnosis made by the surgeon was discussed, challenged, or confirmed from their respective points of view by the physician, the pathologist, and the radiologist, and all to the patient's benefit.

The competent surgeon, said Mr. Cope in conclusion, was assured of an honoured place in the community. To gain the high regard of his fellow surgeons counted for more than any social distinction. If opportunity offered he might have the extra happiness of pursuing some useful work of research. His material reward was greatly varied. Ambroise Paré wrote of a patient who "was cured by the grace of God and made me a handsome present of such sort that I was well contented with him and he with me." But the young surgeon often had a long period of lean years, earning a bare subsistence. Even when elected to the staff of a hospital he might find it hard to make ends meet. But this unsatisfactory state of affairs was likely to find its own remedy. Owing to the decentralization of surgery it was unlikely, and perhaps undesirable, that the rewards would ever be as great as they were in the opening days of the new era. The man who entered the surgical profession chiefly to make a fortune had already made a mistake. The best reward must be always the satisfaction of knowing that interesting, useful, and skilful work had been faithfully performed.

Footnote on Lister

In seconding a vote of thanks proposed by Sir WILLIAM WILLCOX, Sir STCLAIR THOMSON added a footnote to what Mr. Zachary Cope had said about Lister's appearance before the Medical Society of London. He said that he himself had been present in that very room in 1883 when Lister showed the first nine cases of fractured patella in which the joint had been opened and the patella wired. He himself was house-surgeon to Lister at that time and collected and wrote up those nine cases for his chief. It was true that the first cheer which Lister got after five years in London was on that occasion, but it ought to be added on the other hand that one of the most distinguished surgeons of the day who was presiding made the remark: "*C'est magnifique, mais ce n'est pas la chirurgie.*" Lister was very depressed after that reception, in spite of the applause, because at the meeting different surgeons had felt the knees of the patients and had asked: "Is the wire really in there? And is this man a bus conductor, running up and down on his bus? Well, if one of these men had a pyaemia and died, Mr. Lister ought to be tried for manslaughter." Sir Eric Erichsen said that the knee-joint, like the chest and the abdomen, should always be protected from the invasion of the injudicious surgeon. Sir StClair mentioned this to show the changes which had taken place since that time.

Correspondence

Hospital Posts: Responsibility under Supervision

SIR,—During the next five years from 2,000 to 2,500 students will qualify in medicine every year. Owing to the dispersal of teachers, the utilization of makeshift quarters, and the acceleration of clinical studies, their training may be less adequate than in peace time. It will be lamentable if the strain of war-time practice is imposed on these young people without further preparation. Yet most of our hospital appointments have been indefinitely prolonged by the outbreak of war and the normal turn-over of house officers has ceased. This is doubly unfortunate, as there never was a time when the hospitals of this country were more closely integrated or when the advice of consultants and specialists was more uniformly available. Surely this is the ideal opportunity for beginning the system of a compulsory hospital appointment of at least six months' duration immediately after graduation. The rotating service, so usual in Canada and the United States, whereby a man moves through the various departments during one or two years of hospital appointments, would not be practicable, but the exact nature of the appointment does not matter greatly. What is important is that a man should be in responsible charge of patients and yet supported by expert assistance; that he should be living in residence with men and women similarly employed, helping them with a transfusion or a casualty, taking an occasional week-end duty in another department, and talking shop at every meal in the residents' dining room. The growth in mental stature and personality during this period is very great, and it is silly to send men and women to the individual responsibilities of war without it, when the probationary period can so usefully be employed in hospital.

There are in Great Britain some 80,000 beds in voluntary hospitals alone and a total of over 200,000 beds in voluntary and public general hospitals. It would not be difficult to allot each hospital region its quota of graduates every quarter, and a good deal of option and free choice could be exercised within such a system. Complete maintenance plus a salary of £100 per annum would be a fair remuneration for these junior house officers, and the hospitals could then be officered on a more generous scale than has existed in the past or than is compatible with the rates of pay in the present Emergency Medical Service.—I am, etc.,

Radcliffe Infirmary, Oxford, Oct. 10. L. J. WITTS.

Blood Groups in Great Britain

Sir,—In your issue of September 30 (p. 712) Dr. Edward Billing stresses the importance of the genetical and ethnological data on the O, A, B system of blood groups, which should be obtainable from the extensive activities of the blood transfusion service.

With the co-operation of the sectors and depots of the London area we were able, at the Galton Laboratory, to accumulate data on over 58,000 persons, which we put on record at the International Genetical Congress at Edinburgh last August, and which will be published in more detail in the *Annals of Eugenics*. Much of this material has since been subdivided for sex, but in cases in which forms have been already distributed to a large number of hospitals it has not always been possible to effect this subdivision. The Scottish empanelling centres are, however, now sending in material completely classified for blood group and sex. This we regard as of the highest importance. We should, therefore, like to appeal to all empanelling centres now active to co-operate by sending in from time to time numbers classified in eight classes. By so doing they will not only swell the totals and so throw light on points which require very large numbers for their elucidation, but will open up the field, at present wholly unexplored, of the homogeneity or heterogeneity in respect to blood groups of the population of these islands.—We are, etc.,

R. A. Fisher,
G. L. Taylor.

Galton Laboratory Serum Unit at the
Department of Pathology, University
of Cambridge.

Blood Transfusion Technique

Sir,—The booklet describing blood transfusion methods recently circulated by the Medical Research Council contains a section on the adaptation of certain apparatus to the vacuum method of blood collection described by us in the *Lancet* (1939, 1, 388). The advice given in this section is unsatisfactory, and, if followed, will lead to so many failures that its circulation is regrettable. The chief defects are as follows:

Type of tubing to be used for blood collection.—It is necessary for smooth working that pressure tubing should be used. If the tubing distributed by the M.R.C. (No. 8, 3/16th inch internal bore) be used as they suggest it will collapse under the influence of the vacuum and the flow of blood will be impeded. A six-inch length of tubing is also too short for convenience, and about nine inches should be used.

Type of collecting needle.—The 15/10 needle has great advantages over the 24/10 size recommended by the M.R.C. In the first place it simplifies venepuncture, which is an important consideration when blood has to be collected by workers with little experience from donors who are not specially selected for the large size of their veins. The smaller needle will fill the bottle just as efficiently as the larger one, which is in fact more likely to be obstructed by collapse of the vein on to its orifice. The 15/10 needle has the further advantages of lower cost and uniformity with the needles recommended by the M.R.C. for blood administration.

Preliminary filling of the tube with citrate.—We have now performed several hundred collections using dry-sterilized apparatus as originally described, and have never encountered any difficulty due to clotting of blood in the tube. We do not therefore see any reason for this measure, and we disapprove of it because it increases the risk of contamination which our method was designed to minimize and which it has almost succeeded in eliminating. We have cultured seventy bottles of preserved blood collected at this hospital during the early days of the war, in some cases by junior officers recently introduced to the technique. After removal from the refrigerator these bottles were incubated for twenty-four hours before the cultures were made, and they have all been found to be sterile. This desirable standard of sterility will not be maintained if unnecessary manipulations are introduced.—We are, etc.,

C. R. Boland,
N. S. Craig,
A. L. Jacobs.

Mile End Hospital, London E.,
October 9.

Treatment of Fractures

Sir,—In an annotation of Trueta's book on war wounds and fractures (*Journal*, September 30, p. 694) the closed-plaster or Winnett-Orr treatment of infected fractures is described as a method which "contrasts sharply with all accepted surgical principles." This observation is inaccurate and should be corrected, because it encourages a prevalent and somewhat dangerous view that the Winnett-Orr technique is a no-drainage method.

The treatment is actually based on four accepted surgical principles—namely, excision of wounds, free drainage of infected tissues, immobilization of injured soft parts as well as of bone, and protection from oedema by firm external support. The only practice which is abandoned is that of frequent inspection and dressing of the wound, and this is not an accepted surgical principle. It is a practice which is often harmful, has been given up in the treatment of varicose ulcers, and is rapidly disappearing in the treatment of other wound infections. But because the wound is covered with plaster and is not dressed it does not follow that it is not drained. The observation that "no provision is made for drainage or dressing" is very misleading. Provision *must* be made for drainage, and the drainage must be wide, free, and generous. Every infected plane must be freely incised, every recess carefully packed, and the wound converted into a wide open crater. Treatment should in fact be guided by the usual and accepted principles of surgery. The only instinct which the surgeon need suppress is that of demanding a clean dressing. Discharge is harmless even if it accumulates in the dressing and plaster.

Having accepted this, the results are no longer to be described in the terms of your annotation as "extraordinary," "astounding," "revolutionary." What is more reasonable than to immobilize a fracture, drain the wound, and refrain from meddlesome interference? Why should we be astounded that the fracture unites and the wound heals? It is true that by this technique limbs can be saved however grossly comminuted the fracture, however severe and widespread the infection, and however complete the destruction of skin. It is true that amputation has almost disappeared from the repertoire of the traumatic surgeon, and that the mortality has been reduced to a negligible fraction. It is a fact, moreover, despite your reviewer's suggestion, that the method has already been tried out fully in this country in many hundreds of cases over a period of no less than ten years, and that in several fracture clinics it has long been adopted as part of routine treatment. The crushed and mangled limbs of severe motor crashes, which differ in no respect from the injuries of modern warfare, are restored to normal in a very large proportion of cases. But the technique will gain its deserved popularity by proving its soundness and reliability rather than by proclaiming it as an astonishing departure from accepted principles.

Furthermore, we must recognize that it is the second-best and not the first-best treatment of an open fracture. However efficient the treatment of an infected fracture may be, recovery can never be so rapid, so certain, or so complete as when the infection is avoided. The ideal treatment of an open fracture is to convert it into a closed fracture at the first possible moment, and in this way to gain the advantages of rapid union and freedom from bone infection, sequestration, muscle fixation, and adhesion formation, which characterize the repair of closed fractures. The wound is completely excised, devitalized tissue in which organisms can multiply is removed, haemostasis is secured, *no catgut or any other foreign body is buried*, and the skin alone is sutured. A Thomas's splint, plaster slab, or plaster cast with a large window is applied, the wound is exposed to the air to keep it dry, and the limb is elevated to prevent oedema. In many cases first intention healing is secured and recovery is complete in less than half the time which is necessary for the treatment of an infected fracture. Moreover, if the excision fails and infection develops nothing has been lost. The skin sutures are promptly removed, the wound is packed with gauze, and treatment is continued as for an infected fracture.

The two methods are complementary, and the highest standards of fracture treatment demand that both should be used. I submit that the indications are as follows:

Excision and primary skin suture to be used as the first line of treatment, open drainage and enclosure in plaster to be adopted only when this has failed: (1) if the wound is less than six or eight hours old; (2) if the skin flaps can be sutured without tension; and (3) if the patient can be under observation for a few days.

Excision, free drainage of wound, and complete enclosure in plaster to be used: (1) if the wound is more than six or eight hours old; (2) if the skin has been avulsed or is of doubtful viability; (3) if the skin flaps cannot be approximated without tension; and (4) if the patient must be evacuated at once and cannot be kept under observation.

Amputation to be performed only when the main artery is destroyed, so that gangrene is inevitable.—I am, etc.,

Liverpool, October 6. R. WATSON-JONES.

⁂ We welcome Mr. Watson Jones's criticism of our review of Professor Trueta's book, but still maintain that the results obtained by Trueta's methods can truly be described as "astounding."—ED., *B.M.J.*

Anaesthesia in War Time

SIR,—Since the war of 1914–18 the spinal route has gained prominence for anaesthesia of the abdomen and legs. Its usefulness during hostilities merits more notice than "G. D. G." gives it in his admirable discussion in the *Journal* of October 7 (p. 744). Some arguments follow.

In war, hospital organization has to prepare for big rushes of work and for transplantation, since hospitals may have to move suddenly. Cutting down "impedimenta" counts, in which respect "spinal" scores. The handy Luer-Lok syringes and needles, heralded by Pilkin and beautifully adapted to thecal work, fit compactly in a pocket case, and twelve ampoules of anaesthetic pack into a cardboard container. The relative uniformity of dose facilitates use. Posturing the patient preparatory to puncture is routine, and will, of course, entail extra care in already wounded patients, and, in some leg wounds, a small dose of evipan. It is fair to assume even in a C.C.S. that tables could be sloped into a mild Trendelenburg position.

Administration takes but a few minutes. Supervision may be left to an experienced nurse showing aptitude for reassuring patients if timid. The anaesthetist fully conversant with the technique, having injected the drug and seen the operation proceeding satisfactorily, would be available to render the same service to a second patient, and so on, dealing with four or more cases in the course of an hour. Multiple surgical teams often work in one large theatre or adjacent theatres, and the anaesthetist would be on call to deal with a threat of unexpected deterioration in any patient. Great economy in apparatus and personnel results and helps the staff to cope more quickly with sudden crowds of casualties. Subsequent management of the patient is easy and orderly, involving little more than the rule of the recumbent posture for a day or two. It is, in fact, automatic, as the patient is self-controlled, whereas restraining the violent antics of strong men during recovery from (or induction into) general anaesthesia often greatly taxes the nursing personnel and wounded structures. It avoids the danger of using inhalants where a patient arrives with mucosa already inflamed by poison gas or ordinary respiratory infections, and eliminates the risk of ether explosions, which is no less in circumstances of war.

The value of spinal anaesthesia may, from the foregoing, seem assured. Before adopting it we must also cater by other means for wounds above the mid-dorsal region and comply with two requisites. First, an anaesthetist (or sometimes the surgeon) should be skilled in the procedure. Intrathecal injection entails certain refinements in administration which, like its possible pitfalls, are only mastered by experience. Secondly, investigations of the ability of the war wounded to withstand the fall of blood pressure consequent on spinal anaesthesia must be carried out. Thus, exsanguination (as in ruptured ectopic gestation) is a partial contraindication. Shock from wounds of leg or belly is not necessarily a bar, for when the pain derived from the wound is eliminated by the anaesthetic the comfortable relief not only calms but revives the patient. The resilience of a soldier's physique diminishes some of these dangers. The best single guide to safety of spinal anaesthesia will be the blood pressure, which is tested as a pre-operative routine. Already doctors of belligerent States may have collected manometric evidence on this crucial point. Certainly such data are essential prior to the regular use of the method for war wounds. As a possible boon to hospital authorities and the victims of war, spinal anaesthesia may have a place in war surgery, as it undoubtedly has in peace.—I am, etc.,

Bristol, Oct. 14. A. WILFRID ADAMS.

SIR,—The remarks of "G. D. G." call for some comment. It can hardly be denied that chloroform and ether anaesthesia, requiring as it does nothing more complicated than bottle and mask, is likely to prove the most widely applicable method under war conditions, but the insistence on Shipway's apparatus largely removes the advantages of simplicity and portability, and even familiarity, to a large number of medical men.

Chloroform has acquired a bad reputation mainly for two reasons—the frequency of cessation of breathing during deep anaesthesia and the occurrence of primary syncope. The cessation of breathing that so commonly occurs is the main cause of so many anaesthetists and surgeons disliking chloroform intensely; it gives everyone concerned such a fright. Yet Dr. Primrose of Glasgow has pointed out that this is really the action of a defence mechanism of the body to prevent fatal overdosage. It is an indication to cease administration of the anaesthetic, and the patient will recover spontaneously. It is, however, the statement that chloroform and ether are suitable agents for the rapid induction of anaesthesia and, still more, the suggestion that analgesia and not full anaesthesia is all that is required before commencing operations that arouse the most serious misgivings.

It was pointed out to me some years ago that in cases of primary syncope under chloroform it nearly always happens that (1) the patient was not fully anaesthetized, and (2) some manipulation, however slight, had been begun. I am convinced that it is for this reason that such procedures as manipulations, circumcisions, etc., have a particularly bad reputation in this respect. The operation is short, there is a tendency to give just a "whiff" of anaesthetic, and the shock-producing part of the procedure is reached early. To avoid this catastrophe no anaesthetist should be hurried in the induction of chloroform and ether anaethesia, and nothing whatever should be done until full anaesthesia is reached. The old adage, "plenty of air and plenty of chloroform," should be taken to mean not chloroform in large doses but deep enough anaesthesia. "Plenty of time" would be a better expression. Lastly, my recent experience would indicate that as regards recently qualified men capable operators of the more common gas-oxygen machines are not likely to be as scarce as might be supposed.—I am, etc.,

Burnley, Oct. 12. A. DUFF.

SIR,—Your correspondent "G. D. G." gives the impression that in the last war British and French anaesthetists showed a superiority to their American colleagues by their fearless use of chloroform, and praises their greater speed in administration. His opinions are based on war-time experience and as such deserve respect, but might I quote from Henry K. Beecher's *Physiology of Anaesthesia* (p. 256):

> "For years laboratory workers have been warning of the dangers inherent in the use of chloroform; yet the employment of this toxic agent continues in many clinics, chiefly abroad. Presumably the users justify this course by considering that damage follows the use of chloroform only in the exceptional, badly managed case. This is not correct. It has been rightly said that chloroform anaesthesia is synonymous with chloroform poisoning. . . . Susceptibility to the drug varies greatly from animal to animal and from man to man. A brief anaesthesia with chloroform may produce little liver damage or it may prove fatal."

Laboratory experiments show that in *every* case of chloroform anaesthesia some liver damage is produced. The extreme (and unpredictable) case constitutes delayed chloroform poisoning, but in all the others a less degree but analogous form of poisoning is produced, which increases to a maximum for forty-eight hours after the administration. Much work has been done on this, and surely it does not become the British to belittle the more reasoned attitude of the Americans to the agent. Even apart from laboratory work, it is known clinically that the special inherent dangers of chloroform administration—relative overdose and primary cardiac failure—are particularly formidable, especially in the young athletic type, the very class of patient which, as your correspondent points out, is the one under consideration, and especially in the emotional and terrifying surroundings which are known to predispose to hyperadrenalism and consequent ventricular fibrillation.

If hurry must be a factor to provide for, why cannot the safer agents, as vinesthene, alone or in combination with ether, be used for induction prior to ether? The accumulated knowledge of a century should be sufficient to relegate chloroform to a last resource, to be used when no other is available. It is as well to remember that the first warning fatality in chloroform induction occurred in no more than a year following its introduction as an anaesthetic agent.—I am, etc.,

Birkenhead General Hospital, Oct. 7. R. L. WYNNE, D.A.

Radium Precautions

SIR,—Having read Mr. A. R. Greatbatch's memorandum (*Journal*, October 14, p. 782) I am surprised that it was ever considered necessary to stop radium treatment, and I am more than ever pleased that the Royal Sussex County Hospital did not send its radium to be buried in London (a curious place to choose anyway), but continued to use it.

Excluding bomb treatment, the amount of radium employed in any one case is not large, and the chance of that patient being blown to bits (a necessary precursor to the scattering of the radium) must be very small. I wonder how many patients in Barcelona were actually blown to bits while in hospital. It is true that we anticipate bigger raids, but (1) our defences are much better, and (2) London, for example, is much bigger and the patients, therefore, more dispersed.

With regard to the storage of radium not actually in use, I regret that although the Board of the Royal Sussex County Hospital granted my request that we should continue to use our radium, they decided to avail themselves of the generous offer of a member of the Board to pay the cost of a borehole, and to proceed with this work, which, in my opinion, is quite unnecessary. The chance of a direct hit on any one building is small: the chance of one particular part of the building being hit is even smaller. What, then, are the chances of a bomb passing through roof and floor after floor of a substantial building (gradual resistance as against solid concrete), penetrating into the basement, through sandbags, and waiting to burst until it strikes a small steel safe containing drawers of comparatively plastic lead, in which the needles lie—and these needles must be finally burst open if radium dust is to be expelled. It is a common experience that even if this extremely unlikely sequence of events occurs the masonry of a building is likely to fall in over the damaged lower parts, and so spread would be prevented.

It is quite obvious that in war one must take certain risks. In this war we run the risk of being over-organized to such an extent that by the time we have carried out all the safety regulations we shall have no heart to strive for victory. I suggest that we should go about our work as nearly normally as possible, even if this means taking risks. In this way we may preserve our patients' lives and our own morale.—I am, etc.,

Hove, Oct. 14. H. J. McCURRICH.

SIR,—As provincial radiologists may we say how much we endorse Dr. S. Cochrane Shanks's letter in the *Journal* of October 7 (p. 741).

This is an evacuation area, and since the war our population and demands for radium treatment have increased, more especially as many cases formerly sent to London hospitals have now to be treated locally. In spite of this fact the Radium Commission saw fit to bury our stock of radium at the outbreak of war, and no information is forthcoming as to when it will be returned. We fear that if the date of its return is delayed patients may be buried as well as radium.—We are, etc.,

G. P. NORMAN.
Eastbourne, Oct. 9. E. OWEN FOX.

SIR,—May I reply briefly to Mr. Stebbing and Professor Russ (*Journal*, October 14, p. 782). There is a deep and growing anxiety in the minds of many of the profession about the existing radium situation: a feeling that the risks of radium being scattered by bomb explosion are remote, and that the risks of poisoning from this scattering are still more remote. May I suggest that the Radium Commission issue a statement indicating the evidence for their belief that the risks of poisoning from radium inhalation were grave enough to warrant withholding, during the past six weeks, radium treatment from those who urgently needed it.—I am, etc.,

London, W.1, Oct. 16. S. COCHRANE SHANKS.

Gas Protection for Tracheotomy Cases

SIR,—In the *Journal* of September 16 (p. 622) Mr. W. A. Mill refers to the necessity of providing gas protection for tracheotomized patients. It may interest readers to know that a patient here who underwent total laryngectomy by Mr. Colledge last April has had his gas mask adapted by Messrs. Mayer and Phelps. The canister has been removed from the mask and is now carried strapped to the front of the chest. A stout rubber tube connects it with a soft rubber attachment similar in appearance to the face-piece of a gas-anaesthesia apparatus. This is fastened over the tracheotomy opening by means of a strap round the neck. The rest of the mask simply constitutes a protection for the face and eyes, and is not connected with the canister.—I am, etc.,

Glasgow, October 10. DEREK BROWN KELLY.

Treatment of Pulmonary Oedema from Gas

SIR,—After reading Colonel E. M. Cowell's articles about chemical warfare (*Journal*, October 7, p. 736, and October 14, p. 778), may I suggest the treatment of pulmonary oedema of gas casualties by the immediate intravenous injection of 10 c.cm. of a 10 per cent. or, still better, 20 per cent. calcium solution. This injection has already proved effective for a long time in many types of acute oedema, toxic or angioneurotic. Its effect seems to depend on two factors. The hypertonic solution withdraws extravasated fluid back into the circulation and at the same time the calcium reduces the permeability of the capillary walls.

Since the technique is simple, requiring only a 10 c.cm. syringe and an ampoule, it would be possible to give this treatment at a first-aid post. It is to be expected that the results would be best if the injection were given as early as possible, perhaps even prophylactic. There are many calcium preparations for intravenous injection. At the moment the most satisfactory ones are, in my opinion, solutions of calcium laevulate, available up to 10 per cent., or calcium glucono-galacto-gluconate, available up to 20 per cent. The last preparation is also suitable for deep intramuscular injection.—I am, etc.,

London, W.5, Oct. 15. H. L. WINTER.

Psychological Casualties in War

SIR,—It is regrettable that Dr. Maurice Wright has not seen fit to answer the criticisms of his two articles on psychological casualties during war in your issues of September 9 and 16. I made my last letter (September 30, p. 701) vigorous enough, I thought, to stimulate a response, and Dr. Wright will be aware that the validity of a writer's views is bound to be questioned if it is seen that he is not prepared to support his opinions when challenged. On one point in particular I asked for evidence—his statement that there were very frequent relapses among those cases treated by rapid methods. From

Dr. Wright's silence one can only assume that the evidence is not forthcoming, and that the assertion was made, as I suggested, purely on theoretical grounds.

The letter of Dr. J. A. Tippet (*Journal*, October 7, p. 742) appears to provide a partial answer to the question. He says, in reply to Sir Arthur Hurst, that in the course of his work in different "shell-shock" hospitals he saw relapsed cases from Seale Hayne. This was only to be expected; it is a reasonable assumption that relapses occur with every form of psychological treatment. But that is not the point. Dr. Wright's argument was that "very frequent relapses" took place after rapid methods of treatment, and so far no evidence has been brought forward to substantiate it.

Dr. Tippet's experience as a battalion medical officer evidently differed from mine. No doubt he had longer experience in that sphere than I had, particularly as he says he saw many neurotic cases returned to duty after treatment, most of which, no doubt, were from his own battalion. He makes the statement that men, treated by rapid methods and returned to the line, "if they did not relapse were generally quite useless as no one felt inclined to trust them in an emergency." The operative word here would seem to be "as." Of course, if these returned cases were looked upon as a species of psychological half-caste they naturally would become less reliable. I have published records of ten patients with typical "shell-shock" treated by me as battalion medical officer who were able to return to duty in the line after a few days' rest and treatment, and to the best of my knowledge carried on perfectly capably afterwards. With your permission, Sir, as it provides an important illustration of the point, I should like to reproduce a brief description of a case published in 1918 (*Canad. Army med. Bull.*, September, 1918).

> Private B., aged 27, was on duty in the front-line trenches when three trench mortars exploded near him. He was brought down to the aid post with the help of two stretcher-bearers, and when seen sat huddled up, trembling, and shivering in very limb. He looked a limp nervous wreck and could scarcely stand without support. His mind seemed dominated by an obsessing fear; he kept groaning and moaning and started at practically every sound. His hands jerked and trembled so much that he could scarcely pull off his gloves when asked to do so. He had considerable difficulty in speaking; it took him about two minutes to give his regimental number in jerky tremulous accents. He complained of pains in the head and giddiness. He was given morphine and kept for the night in the aid post. The following morning he had greatly improved; he was able to stand up without support, was calm and composed, and spoke without difficulty. The shaking had gone, with the exception of a tremor of the hands. He complained of headache and giddiness, and declared that he had no memory of being brought down to the aid post the night before. The last thing he remembered was being at the entrance to a dug-out after the second trench mortar had fallen. He was kept under observation in the aid post for six days longer; by that time all his symptoms had disappeared with the exception of the amnesia, which still persisted, and he was sent back to duty. He was still serving with his company a month later when I left the battalion.

If Dr. Tippet means his remarks to be taken as a general statement that all cases of "shell-shock" who returned to the front line after treatment were useless he is demonstrably mistaken. As I have previously recorded (*Journal*, July 8, p. 63), I have known men to obtain decorations for bravery after an attack of "shell-shock."—I am, etc.,

London, W.1, Oct. 14. FREDERICK DILLON.

Psychological Treatment Centres

SIR,—Dr. A. C. D. Telfer issues a call to psychotherapists to enlist in service "for defence of the nation's nerves" (*Journal*, October 7, p. 743). Most of us are at present awaiting the call for service with mental casualties, and one can but agree with Dr. Mayer-Gross and others who deplore the lack of arrangements for ensuring early contact between therapist and civil casualty.

As to the local medical officer of health being the "rallying-point" for a psychiatric service, public health services are not so lightly established. What of the local government committees, education and finance? What of the taxpayer and ratepayer? The psychological point of view is spreading slowly, but many public bodies need convincing. But have we, as a body, been very convincing? In what would Dr. Telfer have us enlist; and having enlisted, how would we serve? As psychiatrist to a county authority I discovered some of the difficulties.—I am, etc.,

London, W.1, Oct. 9. R. LOUIS ROSE.

War Hospitals Supply Depots

SIR,—I should be very grateful indeed to any of your readers who can let me have, through your columns, advice and suggestions on the following points regarding the war hospital supply depots. Working parties, to supplement the equipment of Service hospitals, are now actively engaged throughout Great Britain and Northern Ireland. Much of the work they are doing is based upon experience gained in the last war, but changes have taken place in twenty years, as, for instance, with the treatment of the septic wound, which has been changed by many from Carrel-Dakin irrigation to the closed vaseline dressing of Winnett-Orr. Plaster-of-Paris will therefore be used much more than before, and the question arises whether the available stocks of proprietary prepared bandages (in tins or cartons) are sufficient, or should the depots undertake this work? If so, should the dry book-muslin bandages be prepared or should the finished bandage (complete with plaster-of-Paris) be made and preserved in tins?

Bed sand-bags do not feature in the official list—although surgeons' masks in three sizes and abdominal swabs in several varieties, following Army pattern, are being made in most depots—and yet sand-bags almost always seem to be insufficient. Should they be covered with waterproof sheeting, which is easily cleaned by a damp cloth from blood, urine, pus, etc., or by thick calico, which is easier to sew, more serviceable, and more lasting? Sphagnum moss gives rise to another question which is constantly being asked and which should be settled before quantities of this material are collected. Is it needed and is it of any value? It is not yet possible to be certain whether there will be a scarcity of cotton-wool and cellulose in the future, but one wants to be sure that sphagnum moss, if collected, is really going to be used and not thrown out as it was in many places in the last war. The collecting, drying, picking, and placing in bags is too tedious and too wasteful of time unless the result is really worth while. Many nurses found that sterilizing was impossible and that the smell became unbearable, whilst the patient found the dressing about as comfortable as a bag of straw upon his abdomen. Is there any specific therapeutic value in the moss *per se*? Amputation stump caps are not included in the official list, and yet these will save endless dressing and do away with the bandages which only hold on with the greatest difficulty to a conical stump.

These are only a few of the many practical questions which are being asked daily. An answer and suggestions from practising surgeons with practical knowledge of dressings and materials would be greatly appreciated.—I am, etc.,

Belfast, Oct. 10. IAN FRASER.

Specialization in Treatment of War Wounds

SIR,—I am so keen on the subject of specialization that I feel I must put forward a few ideas on the subject.

In the last war we all had to learn by experience what was the best way to treat a wound, but as the war went on cases came to be more and more grouped under men who had had special experience in a particular class of case. My experience was with chest wounds, of which I reckoned about one thousand passed through my hands. In these cases I found it essential to keep a daily record of the physical signs, such as the position of the apex beat, the level and extent of any dullness present, etc., as the signs could alter so quickly. That is only a small detail, but my point is that gun-shot wounds of the chest should be under men who have had experience in such cases. The same applies to gun-shot wounds of the brain, face, abdomen, thighs, etc. I do not think that in war time specialization can be carried too far. My job was to see all chest wounds on admission, decide whether operation was necessary or not, have the foreign body located by *x* rays, and send the report to the surgeon with the patient for removal of the foreign body. After operation I looked after the patient until he was able to be evacuated to the base.

Of course one got mixed cases of chest and abdomen, chest and spine, wounds of the heart, etc., but I am sure that, so far as possible, specialization in one particular line saves lives and prolonged convalescence.

I used to come across American doctors operating on our men at C.C. stations long before any American troops were in the line. In that way they learnt experience on our men, which always worried me at the time; some were quite good surgeons and some were not.—I am, etc.,

Swanage, Oct. 12. W. A. Rees.

Organization of First-aid Posts

Sir,—I have read with keen interest Dr. C. Seely's article on this subject in the *Journal* of September 30 (p. 697), and also Dr. W. N. Leak's able comment (October 7, p. 744). I do not think it is fair either to the patient or to the members of first-aid parties to leave responsibility for disposal of cases in the hands of these men. My experience during the last war was that properly trained men were capable of rendering immediate first aid and bringing the patient to the doctor, from whom the patients were able to receive such further attention as was needed to prepare them for transport to the advanced dressing station, but that few were capable of "exercising discretion in the initial disposal of cases."

Surely the medical officer of the first-aid posts should have this responsibility? The aid post would then be able to discharge its proper function, as laid down in E.M.S./Gen/245, "to arrest haemorrhage, relieve pain, and so prepare those casualties who may be found to require institutional treatment that they can be transferred to the receiving hospital with the least possible harm—that is, by having taken steps to prevent any immediate deterioration." At the first-aid post the patients would receive the immediate and preventive treatment of shock recommended by Colonel E. M. Cowell (April 29, p. 883), and the minimum necessary wound treatment, morphine, serum, etc. Patients would be sent on to the receiving hospital when it was ready to deal with them. The first-aid post would then be fulfilling the important function of "acting as a buffer to the receiving hospital, and so preventing it being overcrowded by the less seriously wounded" and the moribund.—I am, etc.,

Stalybridge, Cheshire, Oct. 10. Eric M. Molesworth.

Manzullo's Tellurite Test for Diphtheria

Sir,—The Manzullo application of potassium tellurite to pharyngeal exudate attracted considerable attention. Your pages in June, 1939 (pp. 1273 and 1275) describe results given by the test which may be misleading.

With the encouragement of Dr. E. C. Benn, the superintendent of the Leeds City Hospital for Infectious Diseases, I have tested 200 successive patients admitted with membrane or exudate. The problem was, Would the Manzullo test help the clinician? Of 113 patients who appeared clinically to be suffering from diphtheria, 103 (91 per cent.) gave a positive swab, while only 96 (85 per cent.) gave a positive tellurite result. Of the 17 tellurite negative, 15 gave a positive swab and one proved fatal. Thirty-nine patients "clinically negative" gave 37 (95 per cent.) negative swabs, while only 21 (54 per cent.) gave a tellurite negative result. Put in another way—of 152 patients, 113 appeared positive clinically and 39 negative; this diagnosis was supported bacteriologically in 92 per cent. while the tellurite test agreed in only 77 per cent. In the "doubtful" clinical group (48 cases), 35 (73 per cent.) were bacteriologically positive, but of these only 18 (37 per cent.) were positive by the Manzullo method also. In this doubtful group the bacteriological evidence, essential for final diagnosis, was supported by the tellurite result in only 23 cases (18 positive, 5 negative)—that is, 48 per cent. One must therefore conclude that the test is of no real help to the clinician, who must found his treatment in the first place on clinical signs.

Professor McLeod very kindly examined cultures from all the 200 cases. There were 75 gravis, 61 mitis, 1 atypical intermedius, and three untyped positive.—I am, etc.,

Leeds, Oct. 5. Hester E. de C. Woodcock, M.B., D.P.H.

The Patellar Sign and Osteo-arthritis

Sir,—Dr. T. C. McCombie Young's letter on patellar crepitus and osteo-arthritis in your issue of September 30 (p. 702) is very welcome as it provides exactly that control group which it is impossible to obtain in a rheumatism clinic—a fact recognized by Dr. McCombie Young, who has indeed done us signal service by his observations. He is, however, mistaken in suggesting that a positive patellar sign is held at the Charterhouse Rheumatism Clinic to be an indication of the actual onset of osteo-arthritis.

It is a fact that every case of arthritis, without exception, whether the knees are affected or not, gives a positive patellar sign. Therefore patellar crepitus in a rheumatic patient obviously constitutes a threat that osteo-arthritis might later develop. Drs. Walker and Sandell have recently demonstrated in a series of sections that crepitus is due to fibrillation from destruction of cartilage. It is for this reason that patients suffering from muscular rheumatism, fibrositis, bursitis, or synovitis are grouped according to the patellar sign. If this is negative even those with quite severely swollen joints are labelled as synovitis or capsulitis, since these clear up and leave no trace. If positive, then even the mildest of rheumatic cases is placed in the group named "early osteo-arthritis" (although osteo-arthritis under proper treatment will seldom develop). The term "early osteo-arthritis" may not be strictly logical, but it must be remembered that it is applied only to rheumatic patients and not to healthy individuals.

Dr. McCombie Young finds that in 15 per cent. of his recruits cartilage was degenerating. The bearing on the aetiology of osteo-arthritis is obvious, and the percentage does not seem too high considering the prevalence of that disease in later decades. Can Dr. McCombie Young tell us whether the 15 per cent. of positives (*a*) gave a family history of cripples, and (*b*) had suffered from rheumatism (excluding fever) in childhood? If not, possibly in further examinations of recruits these questions might be resolved. No doubt the records will be available, so that in future we may find some of this group developing osteo-arthritis, thus confirming our view at the Charterhouse Rheumatism Clinic that osteo-arthritis is a disease which attacks people whose cartilage is constitutionally vulnerable and therefore easily damaged by friction.—I am, etc.,

London, W.1, Oct. 12. H. Warren Crowe.

Vitamin C in Black-currant Juice

Sir,—I should like, through the medium of your columns, to bring to the notice of my colleagues in the medical profession the virtue of matured, freshly expressed, black-currant juice syrup. The vitamin C content (77 mg. per 100 c.cm.) is 50 per cent. higher than that of the common citrus fruits—as a matter of fact it is considerably higher than that of any of the fruits easily obtained in England. Oranges and lemons may possibly soon be difficult to obtain, by reason of either cost or scarcity. Black-currant juice syrup forms a very efficient, in my opinion a better, substitute. Being depectinized it is easily tolerated by all, and especially by children of all ages. It is prepared in England from English fruit. The following is an analysis of its content.

Sugars.—Fructose, 25.4 per cent.; glucose, 26.0 per cent.; sucrose, 1.7 per cent.

Ash.—0.36 per cent.

Iron.—11 parts per million.

Vitamin C.—77 milligrammes per 100 c.cm. by volume, or 61 milligrammes per 100 grammes by weight.

The added sugar is inverted to glucose in the process of maturing. There is also a small proportion of organic iron.

I have for about a year prescribed this syrup in all my cases of gastric and duodenal ulceration, whether acute or chronic, with marked benefit. In all cases it has been well borne and in my opinion has mitigated symptoms.

There is evidence in medical reports that vitamin C is valuable in maintaining the integrity of terminal blood vessels. Possibly ulceration and haemorrhage in the intestinal tract may be due to vitamin C shortage. Being myself a general practitioner, cases of this type are not sufficiently numerous, and the period of observation is too short to enable me to make a full investigation on these lines. Perhaps someone with access to a large number of cases may be sufficiently interested to test this theory. I feel it has great possibilities. The fact that black-currant juice syrup has so large a content of natural vitamin C—and is most pleasant to the taste—may be a valuable asset in treatment. We know that ascorbic acid is a constituent of vitamin C, but if the presence of vitamin P be confirmed, then vitamin C must be looked upon as a complex. I may add that a daily dose of 1 to 1½ oz. contains sufficient of this vitamin to maintain "good health." In cases of acute peptic ulcer the dose can be increased to 3 or 3½ oz.—I am, etc.,

Bristol, Oct. 9. W. H. A. ELLIOTT.

Medical Students in War

SIR,—May I support Mr. R. B. Buzzard's protest (*Journal*, October 7, p. 746) against Dr. Elliot's reference to the emergency war service of medical students. The Minister's answer is tantamount to an accusation of profiteering if they are paid for their services. Why should not these willing and valuable auxiliaries be paid on a sessional basis, and on the same scale as that in force for panel practitioners when engaged in the same type of work? I would go further than Mr. Buzzard and assert that senior medical students by reason of their recent intensive training in hospital and casualty work, their youth, amenity to discipline, and physical fitness, constitute ideal assistants in casualty clearing hospitals. Furthermore, being free from the ties and abstractions of medical practice they can give their whole time to the service during an acute emergency. In these circumstances they are as much entitled to payment for their services as any other category of personnel on the pay-roll of the Ministry.—I am, etc.,

Bradford, Oct. 14. A. HAYES SMITH.

Evacuation

SIR,—On reading the "Medical Notes in Parliament" in the *Journal* of October 7 (p. 751) I was struck by Mr. Henderson Stewart's question regarding "the serious bodily condition of so many of the persons recently evacuated and whether an immediate inquiry into the health services of the cities of Scotland" should not be ordered.

I think the problem has been the same in every reception area, though perhaps more so in some than in others; and a certain percentage of children have arrived suffering from vermin, scabies, or impetigo. These three conditions are recognized as being most frequent among those who have an inherent dislike for soap and water; and if personal and domestic cleanliness were more universal "the large sums spent on the health services in the cities of Scotland," and elsewhere for that matter, could be considerably reduced.—I am, etc.,

Felton, Northumberland, Oct. 10. E. A. WELSH.

"Black-out" Problems

SIR,—Housewives, with their many anxieties, are being worried and made nervous by repeated calls from wardens who complain even of a glow through dark curtains, and this although an official notice directs only screening by dark curtains. Such screening appears more than sufficient for any military purpose, for scientific tests from effective air raid heights would show such illumination as an insignificant fraction or *nil*. Looking down from a mountain at 6,000 feet into a valley on a dark night, glimmers from cottages so screened could not be seen. Greater damage may be done to the community in creating neurasthenic states than could result from lighting of this type. Immured in darkened houses "where," in Milton's phrase, "glowing embers through the room teach light to counterfeit a gloom," there is ample cause for melancholy, and every stress should be avoided which may intensify depression.—I am, etc.,

Ilford, Oct. 10. V. J. BATTESON.

Obituary

G. A. SUTHERLAND, M.D., F.R.C.P.

Consulting Physician, Paddington Green Children's Hospital

Dr. George Alexander Sutherland, C.B.E., who died at Amersham, Bucks, on October 10, was born in Aberdeen the third son of the Rev. James Sutherland, D.D. He was educated at the Aberdeen Gymnasium and at the Universities of Aberdeen and Edinburgh. He graduated M.A. at Aberdeen in 1882, and M.B., C.M. of Edinburgh in 1886, proceeding to the M.D. seven years later, having by that time obtained the M.R.C.P.Lond. and studied at Vienna clinics. Dr. Sutherland was for many years physician to the Hampstead and North-West London Hospital and to the Paddington Green Children's Hospital. He was elected a Fellow of the Royal College of Physicians in 1903 and served as president of the Section of Paediatrics at the Annual Meeting of the British Medical Association in Toronto in 1906, and was also president of the Section of Diseases of Children of the Royal Society of Medicine in 1912. In his earlier years at Edinburgh he had been house-physician to the Royal Infirmary, and an active member of the Royal Medical Society. He was the author of *Treatment of Disease in Children*, which went into a second edition, of the *Heart in Early Life* published in 1914, and his Lumleian Lecture before the Royal College of Physicians in 1917 was entitled "Modern Aspects of Heart Disease." He published *Cyclic Albuminuria* in 1900 and edited a *System of Diet and Dietetics in* EFZB. During the latter part of the last war Dr. Sutherland was a consulting physician to the Royal Air Force, and for his services received the C.B.E. in 1920.

HARVEY CUSHING

Sir Charles Sherrington, O.M., G.B.E., writes:

I should be glad if you would allow me, as one of the many who regarded Dr. Harvey Cushing with affection, a few words of personal tribute. It is just forty years since I first had the good fortune to come to know him. It was at Liverpool, and he was then on his way home to America from Kocher in Berne. He called on me at the Physiological Laboratory, and then prolonged his stay with us to some eight months. He was already interested in cerebral surgery. He joined with enthusiasm in the experimental work going forward in the laboratory upon the brain of the anthropoid apes. The day following a final experiment would find him early in the laboratory, devoting himself to making a series of drawings of the undissected brain showing its surface markings, blood vessels, etc., appropriately coloured, providing a valued addition to the maps and protocols of the day before. His drawings were beautifully executed, and the Royal College of Surgeons preserves at least one of them now. He had before coming to the Liverpool laboratory completed a memorable piece of experimental work on the cerebrospinal fluid; the findings of this, with his usual frankness, he put our laboratory fully abreast of, although they had not yet actually seen the light in print. He became at once an "intimate" among our small company of research workers, mostly neurological. He had from all of us respect and affection. When in the latter part of the summer vacation the time came for us all to disperse I know he took with him lasting friendships.

Five years later I saw him in his own home in Baltimore. There I found him, house to house, beside his elder and close friend William Osler. "Close" describes the relation between them altogether too baldly. It was friendship whose intimacy and reciprocal devotion and loyalties can, for those who had not the opportunity of witnessing them in the life, perhaps best be understood from the pages of the "Life" which Cushing in later years wrote of Osler. Surely a "Life" which not the subject of it only but the authorship no less combine to make a tribute our whole profession may regard with pride as an example of brotherhood within its fellowship.

My own contacts with Harvey Cushing were throughout the years an unalloyed pleasure to me. On a trip to America one of the greatest rewards always was to have there a re-meeting with him. Conversely, to welcome him on this side gave when it happened a fresh zest to the whole routine of daily things. It was my privilege to know many of his pupils; if ever a teacher had the affectionate respect of all those who could call him "Master" it was Harvey Cushing. The unequivocal evidence and consciousness of this was, I think we should find, if we could know, perhaps among those assets of his life which he himself most prized. His death leaves our world the poorer by the loss of a personality of transcendent accomplishments and of singular charm.

Oct. 9, 1939.

Mr. Geoffrey Jefferson writes:

Harvey Cushing's was one of those vital personalities, rare in any profession or in any walk of life. Halsted undoubtedly exerted a profound influence upon him during the formative years of his more mature growth, and he was wont to tell an amusing story, too long to relate here, of their first meeting and his conversion from the ultra-rapid methods which were the vogue elsewhere. Halsted's insistence on the utmost care in the recording of every clinical and pathological fact, whether it might seem relevant at the moment or not, on the utmost gentleness in the handling of tissues, on the minimizing of blood loss and shock, on painstaking rather than brilliant operating, met with an instantaneous and understanding response in the young Cushing. He modelled himself upon his master and transferred the Halsted technique to a branch of surgery to which it had not hitherto been applied. His use of iron-dyed black silk for ligatures, his condemnation of catgut, and his applications of silver-foil dressings were copied from his master. The dominant figure in neurosurgery in Cushing's day was of course Victor Horsley, with Macewen looming more silently yet forcefully in the background. Cushing went to London hoping to work with Horsley, but found him so engrossed in his many pursuits that he felt that there would be little opportunity for him to learn. It would be interesting to speculate whether the preoccupation of Horsley with problems of neurophysiology would have left a mark on Cushing's work. His brief stay with Sherrington certainly did so. As it was, the more mechanistic work which he did in Berne on the effects of cerebral compression on blood pressure proved to be extremely useful to him in a practical way. We find him treating his patients and recording his experiences in the journals as if they had been physiological experiments on man. No surgeon in our time has maintained so high a level over so long a period.

Things were already going well for him at Johns Hopkins, where he had risen to be associate professor of surgery, when his bold diagnosis and fortunate operation on the man who was to become General Wood focused attention sharply on him. Cushing once recounted to me the full details of that famous case. He felt sure that it was this operation, witnessed by Cabot of Boston, which brought him to the Moseley Chair of Surgery at Harvard University (1912). The correctness of the choice was made apparent to the whole world by the publication in the same year of his famous book on the pituitary body. It would be absurd to attribute the rise of endocrinology to the fact of this book alone, but there can be no doubt that it profoundly affected medical thought. In 1917 his book on tumours of the nervus acusticus set the seal on his reputation. From that time onwards his work followed on predestined lines. It lay first in the classification of the tumours of the central nervous system, based on the observation that neoplasms tend to occur in certain situations, to be regional in type. It would be untrue to give the impression that this thought had not occurred to anyone else, but certainly Cushing went much further than any of his contemporaries in deducing pre-operatively the probable nature of the tumour from a consideration of the history, of the signs, and of the laboratory tests. His major contribution was something bigger than a study of cell structure. His system of following up his patients, of keeping in constant touch with them, of making them feel that here was a friend as well as a surgeon, enabled him to acquire a remarkable grasp of the natural histories of the tumours themselves, of their duration, and of the expectation of life with different types. His last great book on the meningiomas shows very well what could come out of a systematized clinic. He had planned to write this book with George Heuer when he was at Baltimore, on the basis of twelve cases, and he always said that it would have been a much better and more readable book than the one that finally appeared, which was based on over 300. When one tries to assess the most important contribution made by Harvey Cushing I think that one must give pride of place to the purely humanitarian fact that he had a lower mortality than anyone else, either before him, or contemporaneously. His mortality indeed appeared so fantastically low to some that they openly refused to credit it. There can be no doubt whatever that it was strictly accurate. What perhaps made it more difficult still for the average man to understand was that he spent more hours over a single case than the general surgeon spent upon half a dozen. All the Baltimore School were slow operators, but in neurosurgery there was the more reason for it because there was everything to learn, and because impatience might well lead to disaster. Others did not see that this was the cause of his success and that the Halstedian principles upon which he had been brought up were the foundation of everything.

Many of the great pioneers have been great individualists; it falls to few to found a school. Horsley and Macewen are examples of this lapse in our own country. Cushing attracted people to his clinic from all over the world; they made themselves his pupils, his disciples, and his friends. He had the same nebula of excitement as T. E. Lawrence; few can ever have had such a stimulating personality. The process of stimulation could be somewhat painful to the co-worker, who left "The Chief" to play his part elsewhere fired with an ability which he would never otherwise have developed, yet somewhat ruefully licking his wounds. Few people could be more devastatingly charming than he; few were more ruthless in their onward drive. But if he drove others, he also drove himself. There was a strong streak of tenderness in his personality that drew one irresistibly to him, a trait very readily recognized by his patients. He was strangely incurious about other people, and though he liked to hear about them he never gossiped. There is no doubt that he was a great artist; there was something electric about him, a stimulus to be got obtainable nowhere else; the sick instantly felt confident in him. His ideal was of the highest: the arduous and ascetic advancement of learning. Considerations of money never entered into his calculations, and although he had a sufficiently lucrative practice he disparaged fees out of proportion to the service rendered. Though often in great discomfort, it was characteristic of him that he never mentioned his own ailments and even actively discouraged discussion of them—an unusual human trait. In his later years, when he alternated between a wheeled chair and the most incongruous bursts of activity, he still retained all his old fire. His entrance to a room could be relied upon to have the same effect: that sudden heightening of interest, that anticipation which was so rarely disappointed as that unexpectedly deep voice was heard and as those lean fingers intertwined. Harvey Cushing was truly one of the great figures in medicine of all time. He has set a standard of performance which we shall not forget, even though we cannot equal it.

J. D. COMRIE

Dr. HARLEY WILLIAMS sends the following appreciation:

The late John Dixon Comrie will be remembered by generations of Edinburgh students for his lectures on the history of medicine. This course was not compulsory for the degree, but the minority who were curious enough to attend the first meeting all became Comrie's adherents. A tall, stooping figure, he would slink into the room wearing the old-fashioned high collar above which a face with exceedingly black eyes and moustache scanned the small but faithful band. He would show one slide after another by a small lantern on the bench before him. Bending over in the light of the carbon arc, his huge shadow thrown up behind, Comrie resembled a humorous Mephistopheles, and he described the wonders of medical history in an unscholastic but very interesting way. It was not mere knowledge out of a textbook; his information, like his pictures, had been gathered over years, and his slides were a miscellaneous collection of portraits, maps, manuscripts, and famous scenes. He would expound them with an air of modest enthusiasm as if he shared the astonishment of his audience. Ever since those lectures my notions of Hippocrates (with a photograph of the island of Cos), of Avicenna, and Vesalius (shown in his great lecture theatre), the martyrdom of Servetus, and the circulation of the blood (with illustrations from Harvey's writings) are founded on Comrie's penetrating descriptions. He knew exactly the way to make vivid the distant situation, and with a conjurer's art he could produce exactly the picture needed to complete his effect. His students owe to Comrie their insight into the tremendous background of medicine. He was born in Buchan, that north-east shoulder of Scotland above Aberdeen. Perhaps from that stern coast came his laborious persistence in acquiring materials for his writings on medical history. He was too absorbed in such things and had too logical a mind to develop the large practice which his skill justified. But he was not a mere collector of relics and memorials, for he could make the design to fit them. He rescued names from oblivion, and his own will be remembered, as he had the gift of fixing for the benefit of the future many otherwise forgotten aspects of the changing face of medicine.

•

We regret to announce the death on September 24 of Dr. CHARLES J. J. HARRIS of Moresby Hall, Whitehaven. Educated at the Royal Naval College and Charing Cross Hospital, he took the L.S.A. in 1883, the English conjoint diplomas in 1897, and the M.D. of Durham in 1901. As a young man he became house-surgeon to the Whitehaven Hospital, and after three years began general practice but retained his connexion with the hospital, and at the time of his death was an honorary consulting surgeon, a member of the general committee, and a life governor. Dr. Harris was a strong exponent of the outdoor life and was associated with the Boy Scout movement for more than twenty-five years, becoming County Commissioner for Cumberland, and received the long service medal. During the war he served with the Border Regiment and later with the Artillery Brigade, rising to the rank of major. Whitehaven miners, for whom he worked for so many years, owed him a deep debt of gratitude. During the Wellington pit disaster in 1910 he risked his life in penetrating into the distant workings with the rescue parties, and for this he was awarded the King Edward Medal. Dr. Harris took a keen interest in the municipal health service, in the work of the St. John Ambulance Association, and of the British Legion. He was a member of the Cumberland and Westmorland Antiquarian and Archaeological Society and joined the British Medical Association as long ago as 1887. Full military honours were accorded at the funeral at Moresby Parish Church on September 27.

•

Dr. AUGUSTUS MAYBERRY WHITESTONE, who died on October 7 at Hollingbourne, near Maidstone, had practised there from 1894 until his retirement some years ago. Born in Dublin on October 29, 1856, the son of Berkeley Whitestone, he was educated at Armagh Royal School and Trinity College, Dublin, graduating B.A., M.B., B.Ch., and taking the L.M. of the Rotunda Hospital in 1883. He was for three years assistant surgeon to the County Down Infirmary, and after settling in Kent at Hollingbourne became medical officer to the local workhouse and the hospital for infectious diseases, and public vaccinator. In his student days Dr. Whitestone was a leading rugby football player, representing Dublin University and Ireland. He had been a member of the British Medical Association for fifty-six years.

Universities and Colleges

UNIVERSITY OF OXFORD

In Convocation on October 12 the Vice-Chancellor, Mr. G. S. Gordon, President of Magdalen, made his annual speech, dwelling particularly on the influence of war, and the prospect of war, upon university life. With regard to the Faculty of Medicine he said that the decision to evacuate London had thrown on the University of Oxford "the obligation of providing our medical students with clinical training, a new and formidable experiment which the Regius Professor and his colleagues are tackling in great style. And it has filled, or is filling, more than half our colleges with Government officials."

UNIVERSITY OF CAMBRIDGE

MEDICAL STUDENTS UNDER WAR CONDITIONS

With a view to expediting the qualification of medical students who have resided for six terms, and are so well advanced in their studies as to be ready for the clinical instruction which is normally received elsewhere and cannot be provided within the University, the Council of the Senate has resolved that medical students who have completed two years of residence and have qualified in anatomy and physiology be allowed to count residence while attending approved courses of clinical instruction away from Cambridge. For the benefit of students who wish to expedite those parts of their medical training which are done within the University, the General Board recommends that candidates for the Final M.B. Examination be not required to have obtained honours in a Tripos or, being over the standing for honours, to have attained the honours standard in the Natural Sciences Tripos; and a Grace putting into abeyance for the present Regulation 8 (*d*) for the degrees of M.B., B.Chir. is to be submitted to the Regent House.

RETIRING VICE-CHANCELLOR'S ADDRESS

At a Congregation held on October 2 Professor H. R. Dean, M.D., Master of Trinity Hall, resigned the office of Vice-Chancellor and made an address to the Senate on outstanding events in the past academical year. Among the deaths of resident members of the University he mentioned Dr. Charles Cyril Okell, whose contributions to bacteriology had added much to knowledge of the origin, detection, and prevention of bacterial diseases. The Vice-Chancellor said that the new Anatomy Laboratory was finished just before the beginning of the Michaelmas Term and had been in use throughout the year. Speaking of recent events he said: "In sharp contrast to the confusion and uncertainty which marked the crisis of September, 1938, the outbreak of war found members of the University prepared and ready to undertake unaccustomed duties. Many members of the University staff have already left Cambridge to hold commissions in the fighting forces or posts in the Civil Service. Those who remain in the University have cheerfully shouldered some extra burden of labour or responsibility. Our country possesses in the undergraduates and younger graduates of the Universities a supply of young men admirably equipped to take a leading part either as officers of the fighting services or in the study of the scientific and technical problems on the solution of which success in modern warfare depends. In the difficult times which lie before us young men trained in Cambridge laboratories are well fitted both to advance and to employ scientific knowledge for the maintenance and improvement of national defence. . . . During the earlier months of the year and during these last few weeks the Cambridge Colleges have met most willingly the requests made to them on behalf of the Government or by the Colleges of the University of London which sought their hospitality. . . . Within a few days of the outbreak of war the students from the London Hospital and from St. Bartholomew's began to work in Cambridge. They have been joined by our own students, and the laboratories of the Medical School have presented for some weeks a scene alive with all the many activities of Full Term. But the teaching work of the University will not be confined to the laboratories; for, as a result of the Government's decision to defer the obligation of military service for men below the age of twenty years, the Colleges expect a large number of Freshmen. Undergraduates whose services will not be needed by the Government in the immediate future will begin or continue their studies at the University, with the knowledge that by their work at Cambridge they will make their best contribution to the welfare of this country."

The following candidates have been approved at the examination indicated:

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.—*Part II:* E. H. Allen, R. B. Boal, A. H. Brockbank, O. C. Levine, H. M. Marks, M. P. G. O'Brien, S. R. Reynolds, K. V. Shetty.

UNIVERSITY OF MANCHESTER

Dr. D. D. Cranna has been appointed Assistant Lecturer in Anatomy.

The following candidates have been approved at the examination indicated:

DIPLOMA IN PUBLIC HEALTH.—*Part 2:* H. S. Bagshaw, Jessie R. Davidson, H. N. Osborne, F. Stratton, H. Williamson. *Part 1:* Mary A. Rogerson.

UNIVERSITY OF SHEFFIELD

Mr. C. D. P. Jones, F.R.C.S., has been appointed honorary demonstrator in anatomy.

The Services

CHEMOTHERAPEUTIC AGENTS FOR SEPTIC WOUNDS

PROPHYLAXIS AND TREATMENT

The following memorandum concerning the use of sulphonamide derivatives for prophylaxis and treatment of wound infections is being distributed from the War Office to all officers of the Royal Army Medical Corps. It is emphasized that the memorandum is provisional.

War Office Memorandum

Preamble.—Experimental and clinical results having proved the effectiveness of sulphonamide derivatives in the treatment of streptococcal infections and having indicated that these compounds have also an action on anaerobic gas forming bacilli it is recommended that these compounds be given a trial in the field. In principle the earlier the drug is administered the more effective is the result, but some benefit may be anticipated even in well-established infections.

For the time being it is recommended that all wounds which from the clinical aspect appear likely to become the site of secondary coccal or gas gangrene infection should receive a prophylactic course of sulphonamide treatment at the *earliest possible opportunity* and that this prophylactic course should be extended if definite infection supervenes.

Designation of Sulphonamide Compounds in common use.—(1) Sulphanilamide (synonyms: sulphonamide-P, colsulanyde, streptocide, prontosil album). (2) M & B 693 (synonyms: sulphapyridine, dagenan). (3) M & B 693 soluble (synonym: dagenan sodium).

Administration

(*a*) GENERAL PRINCIPLES

(1) A prophylactic course should occupy about 48 hours.

(2) Courses of treatment for established or developing infections should extend over ten days, but if not effective by this time an interval of 48 hours should be allowed before continuing treatment.

(3) When an infection appears to be controlled, as judged by the temperature, small doses should be continued for a further 3–5 days in order to prevent relapses.

(4) The principle of effective treatment is to obtain a high blood concentration of the drug as rapidly as possible and to maintain this concentration at an effective level over a period of time. Because the drugs are rapidly excreted it is necessary, in order to maintain an effective level, to administer four hourly *night and day*.

(*b*) PRECAUTIONS

Certain individuals are unduly sensitive to the drugs and there is no evidence yet available for assessment as to whether persons suffering from shock may not be even more sensitive. The reactions that may occur can be classified as (1) *Mild,* (2) *Serious.* The following is a list of such reactions together with comments as to how they are best avoided or treated.

(1) *Mild*:

Nature of Reaction	Remarks
Cyanosis:	Incidence reduced by prohibiting sulphur containing foods and especially by the avoidance of saline purges and drastic purges. Liquid paraffin the best laxative. Cyanosis may be temporarily dispersed by giving 0.5 to 1.0 g. per day of methylene blue by the mouth. Cyanosis *per se* should not prohibit continuance of treatment.
Acidosis:	Treat by oral administration of sodium bicarbonate.
Drug fever:	Requires to be distinguished from fever due to recrudescence of infection. If true drug fever, omit drug.
Dermatitis:	Omit drug and induce diuresis with water or simple diuretic. May be the prelude of more serious complications. Check leucocyte count if possible.
Dizziness, headache:	If intolerable, administer fluids freely. Check leucocyte count if severe.
Leucopenia:	Negligible unless rapidly progressive to below 3,000 leucocytes per cmm.
Haematuria (MB 693 only):	Administer fluids freely.
Jaundice Neuritis }:	Omit drug. Induce diuresis. (*See* also haemolytic anaemia.)

(2) *Serious*:

Agranulocytosis:	Occurs after 10 days or more of treatment. Incidence rare. Leucocyte count only method of diagnosis. Other symptoms: headache, deterioration of condition, fever, sore throat. Treat by transfusion and pentnucleotide.
Haemolytic Anaemia:	Occurs early (2–4 days). Incidence rare. Mortality low. Early signs jaundice and haemoglobinuria. Omit drug, induce diuresis, transfuse if necessary.

(*c*) DOSAGE

(1) *Sulphanilamide.*—Tablets should be powdered and administered suspended in milk or water.

Prophylaxis.—4 g. (8 tablets) statim followed by 2 g. (4 tablets) in four hours' time followed by 1 g. (2 tablets) four hourly night and day for a period of 48 hours. If infection develops continue as for "treatment."

Treatment.—4 g. (8 tablets) statim followed by 2 g. (4 tablets) in four hours followed by 1 g. four hourly night and day for a maximum period of ten days. If infection is still uncontrolled allow an interval of 48 hours and then repeat the same course from the beginning or, if available, change on to M & B 693. If infection appears to be controlled during the first or later courses reduce dose to 0.5 g. (1 tablet) four hourly and continue for 3-5 days after the temperature has become normal.

Note.—During the first course of treatment if no clinical effect is evident within three days it is recommended that a change be made to M & B 693. But if some clinical effect is obvious it is worth while pursuing the full course of sulphanilamide.

(2) *M & B 693.*—Tablets should be powdered and administered in milk or water. If vomiting is troublesome split the doses and give at shorter intervals, *e.g.*, instead of administering 1 g. four hourly give 0.5 g. two hourly.

Prophylaxis.—3 g. (6 tablets) statim, followed by 2 g. (4 tablets) in four hours' time followed by 1 g. (2 tablets) four hourly night and day for a period of 48 hours. If infection develops continue as for treatment.

Treatment.—The same procedure as for sulphanilamide except that the initial dose is 3 g. (6 tablets) instead of 4 g.

(3) *M & B 693 Soluble.*—This substance is of great value when swallowing is impossible or when gastric upset prevents absorption of the oral compound. It consists of a 33 per cent. solution (1 g. in 3 c.c.). Injections are best made intramuscularly, but as the solution is alkaline some reaction at the site of the needle puncture is common unless care is taken to inject deeply and avoid escape into the subcutaneous tissues. The solution may also be injected intravenously if the dose is diluted with 20 c.cm. of sterile distilled water or normal saline. The drug may also be added in suitable quantity to intravenous drop transfusions of saline or blood (at the rate of 1 g. per four hours).

Dosage Prophylactic and Treatment.—1 g. (1 ampoule) four hourly night and day, the prophylactic course being completed in 48 hours. The treatment course may be continued for ten days, but it is strongly recommended that a change over to the oral compound be effected at the earliest opportunity. The soluble compound finds its best use in the initial phases of a course of treatment and should not be regarded as a substitute for the oral compound; it should only be used for a continuous course when oral therapy is impracticable.

HONORARY PHYSICIAN TO THE KING

Colonel F. Whalley, D.S.O., T.D., T.A., has been appointed Honorary Physician to the King as from July 7, in succession to Colonel H. T. Bates, O.B.E., T.D., T.A., who has retired.

DEATHS IN THE SERVICES

Surgeon Captain **Reginald Thomas Alexander Levinge**, R.N. (ret.), died recently at Bournemouth. He was educated at Trinity College, Dublin, where he graduated A.B. in 1882, and in the school of the Irish College of Surgeons, and took the L.R.C.S.I. in 1885 and the L.R.C.P.I. in 1886. He entered the Royal Navy soon afterwards, attained the rank of fleet surgeon on February 22, 1904, and became surgeon captain on October 3, 1908. As surgeon of H.M.S. *Alecto* he served in the punitive naval expedition commanded by Rear-Admiral Rawson in 1897, and landed with the force sent to punish the King of Benin for the murder of the members of a political party, and took part in the capture of Benin City on February 18, 1897. When Lieutenant-Commander Pritchard was shot Surgeon Levinge took command of the party and led it with success. He was mentioned in dispatches and received the General Africa Service Medal, with Benin clasp.

Lieutenant-Colonel **James Burne Lapsley**, M.C., I.M.S. (ret.), died at Mont Cantel, Jersey, on October 7, aged 55. He was born on August 16, 1884, was educated at Queen's College, Cork, and graduated M.B., Ch.B., B.A.O. of the Royal University of Ireland in 1907. He entered the Indian Medical Service as lieutenant on February 1, 1908, became lieutenant-colonel after twenty years' service, and retired on April 20, 1935. He served throughout the war of 1914–18, and received the Croix de Guerre on August 31, 1917, and the Military Cross on June 3, 1918. He was appointed assistant director-general (stores), Indian Medical Service, on November 27, 1926, vice Lieutenant-Colonel G. G. Hirst. He had been a member of the British Medical Association since 1912.

Medical News

The Society for the Protection of Science and Learning has changed its address from 6, Gordon Square, London, W.C., to Scott Polar Research Institute, Lensfield Road, Cambridge.

Until further notice *La Presse Médicale* will appear once a week instead of twice weekly as hitherto.

The congress of the Italian Society of Plastic Surgery, which was to have been held at Naples on October 21 and 22, has been cancelled.

The Library of the British Medical Association will be open from 9.0 a.m. to 5.0 p.m. (1.0 p.m. Saturday) until further notice.

By arrangement with the Ministry of Health the out-patient department of the Golden Square Throat, Nose and Ear Hospital has now been reopened.

The Child Guidance Council has changed its address to 23, Queen Square, Bath (telephone: Bath 2390).

Owing to the war the council of the Zoological Society of London has decided for the present to discontinue its fortnightly scientific meetings.

The Ministry of Health in a communiqué dated October 13 announced a visit by the Queen to a casualty evacuation train. Her Majesty was received by the Minister of Health, Dr. Walter Elliot, Captain Euan Wallace, Minister of Transport, and the official party also included Sir George Chrystal, Secretary of the Ministry of Health, Dr. J. H. Hebb, Director-General of the Emergency Medical Service, and Miss K. C. Watt, Principal Matron for Emergency Nursing Services. The primary purpose of these trains is to evacuate air raid casualties from the advanced base hospitals in vulnerable areas to the base hospitals in outer areas. A train crew consists of one medical officer, one hospital train officer, three trained nurses, ten auxiliary nurses, and eight St. John Ambulance Brigade orderlies. Nursing staff is supplied by the Civil Nursing Reserve, and about 400 nurses are employed on the trains. A description of a casualty evacuation train is published in this week's *Supplement* at page 208.

It is announced in the *Times* that eighteen Egyptian medical men resident in England have, through the Egyptian Ambassador in London, offered their services to the British Government wherever they can be useful in the present circumstances. The Secretary of State for Foreign Affairs has expressed to the Egyptian Ambassador the Government's high appreciation of these generous offers.

On October 13 two claims against the Corporation of Croydon in respect of the death of two schoolboys in the Croydon typhoid epidemic were disposed of in the King's Bench Division by Mr. Justice Stable on payment of agreed damages aggregating £1,638.

Dr. J. Trueta, late director of the department of surgery, General Hospital of Catalunya, Barcelona, will read a paper on "The Organization and Treatment of War Casualties" before the Section of Orthopaedics of the Royal Society of Medicine (1, Wimpole Street, W.) on Tuesday, October 24, at 2 p.m. Members of the Sections of Anaesthetics, Medicine, Surgery, and United Services are invited to attend.

Dr. Richard W. B. Ellis, assistant physician to the Children's Department of Guy's Hospital, and joint editor of the *Archives of Disease in Childhood*, left London on October 12 for Rumania as one of a delegation of three from the Friends' Service Council to inquire into the possibilities of relief work among Polish refugees. The delegation are taking with them a grant from the Anglo-Polish Relief Fund for immediate use in necessitous cases.

Medical Notes in Parliament

The House of Commons this week made progress with a Bill to suspend local elections and the registration of electors. The Prices of Goods Bill was down for second reading. Debate arose on the adequacy of the allowances for the families and dependants of soldiers and on war pensions. Statements were made in both Houses on the progress of the war and on air attacks against Great Britain.

At a meeting of the Parliamentary Medical Committee on October 13, Sir Francis Fremantle in the chair, a report was received of the visits paid by Sir Francis and Dr. Haden Guest to first-aid posts and on suggestions made to the Ministry of Health. Sir Francis Fremantle also reported on his interview with the chairman of a local regional committee and a consultant specialist about the defective organization of a public assistance institution as a civil emergency hospital owing to lack of co-operation between the local authorities concerned. The Parliamentary Medical Committee discussed the petrol ration to medical men, on which Sir Francis Fremantle had introduced a deputation of the British Medical Association to the Minister of Mines. Other subjects considered by the Committee included the disabilities of consultants in the civil emergency scheme; the under-employment of medical officers in hospitals, civil and military, at present empty; the medical care of dispersed military units in the United Kingdom, and the departure from the United Kingdom of military units without vaccination or inoculation. The Committee decided not to take action on the allocation of war wounded between military and civil hospitals. It agreed to represent to Sir Kingsley Wood the desirability of appointing women medical officers for service with women's establishments attached to the Royal Air Force.

There has been presented to Parliament the report of Lord Weir's conference on war damage to property. This conference has failed to find or devise any practicable or justifiable scheme for mutual protection against the risk of war damage to fixed property in private ownership. A promise of State assistance is renewed.

Commandeered Hotels at Spas

In the House of Lords on October 11 Lord GREVILLE adduced complaints against the commandeering by the Government of hotels at British spas. He said many thousands of sufferers from rheumatism, including miners, sought treatment each year at these spas. In war time the number of these people was likely to be increased. In consequence of exposure on military service there would arise, as the last war showed, many cases of rheumatism, neuritis, arthritis, and kindred elements. He asked whether any competent medical authority had been consulted when hotels at spas were commandeered. He understood the Ministry of Health occupied itself in commandeering accommodation for lodgings. Were the medical men who lived in these spas consulted? In some places practically no accommodation was left.

Earl STANHOPE regretted that inconvenience had been caused to individuals. The Government had to take precautions to ensure the functioning of the Departments dealing with the social services such as national health insurance, and to see that alternative accommodation was available in the event of air attack. Large buildings had to be found, and few provincial towns save spas and holiday resorts afforded accommodation suitable for offices. Three spas had been reserved for those who might suffer from rheumatism as a result of service with the Forces. That had been considered by a committee representing the Ministry of Health and the Service Departments. There was not actually a doctor on that committee. He was advised that accommodation would also be available for the public who required treatment, though not such good accommodation. Facilities at most hydropathics were still available for the general public.

Army Medical Services in France

Mr. HORE-BELISHA announced on October 11 that 158,000 men had been transported to France within five weeks of the outbreak of war. Sir FRANCIS FREMANTLE asked whether full provision had been made for the health of the troops on the medical and sanitary sides. Mr. HORE-BELISHA replied that the Director-General of the Army Medical Services was acknowledged by the medical profession to be a man of the highest reputation. Civilian doctors were satisfied on the whole with the skill and powers of organization of the R.A.M.C. The medical profession had a free hand to do everything which was of advantage. He would willingly hear suggestions from Sir Francis Fremantle.

Hospital Treatment of London's Civilian Population

Dr. ELLIOT told Sir Ralph Glyn on October 12 that there were normally approximately 97,000 hospital beds in the metropolitan police area, excluding beds for mental patients. Under the Emergency Hospital Scheme an additional 14,000 beds had been set up in hospitals in the outer parts of the area. Approximately 13,000 beds had, for the time being, been closed in certain of the inner hospitals. Beds now available in the metropolitan police area numbered 98,000. Approximately 55,000 were immediately available in hospitals in the area of the London Sector Scheme (which was rather larger than that of the metropolitan police area). These could be used either for casualties or for ordinary sick in need of in-patient treatment. Hospitals had been instructed to admit to their unoccupied beds all cases requiring in-patient treatment.

Dr. ELLIOT further told Sir Ralph Glyn that many of the beds in the general hospitals were available for children, and although figures did not distinguish children's beds from adults' beds, he understood that in general there were beds for all requiring hospital treatment. The ordinary hospital services remained available. There should, therefore, not be difficulty in obtaining specialist treatment for children who remained in London.

Mr. PARKER asserted on October 11 that out-patients from London hospitals, who had been told to attend their local hospitals during the war, had now been told to go to a local doctor. Miss HORSBURGH answered that no instruction had been given under the Emergency Hospital Scheme that persons who normally attended at hospitals for out-patient treatment should go to a local doctor instead. At the beginning of the war some London hospitals temporarily closed their out-patient departments of their own volition, but most of these had now been reopened.

House Officers and the E.M.S.

Mr. PARKER asked on October 12 whether the sector officers in charge of the Emergency Medical Service in various districts were consulted before the dispatch of the letter of dismissal from the Service sent out by his Department on October 6 to a large number of doctors. Dr. ELLIOT answered that the letter was sent out in error. All Group Officers had now been advised as to the actual position of the doctors in question. The Ministry of Health would fulfil obligations incurred during the past five weeks to the doctors.

Release of Doctors from E.M.S.

Dr. ELLIOT stated in reply to Sir Ralph Glyn that as regards the release of members of the medical profession to carry on their normal duties, arrangements had been made whereby doctors could either go on indefinite leave, subject to recall if required, or (with the exception of doctors filling posts as registrars, house-physicians, and house-surgeons) go on part-time service under conditions recently drawn up in accordance with the advice of a committee. That committee was as follows: Sir Bernard Docker (chairman); Dr. G. C. Anderson, Sir Girling Ball, Dr. H. E. A. Boldero, Lord Dawson, Mr. C. H. S. Frankau, Sir Cuthbert Wallace, and Sir Charles Wilson. The conditions referred to were:

1. Each officer who was transferred to part-time would make his services available to the State, if required, for the equivalent of four days in every week, the remainder of the time being at his own disposal. The precise manner of giving effect to this condition—that is, the particular days or parts of days when the officer was to be on call—would be a matter for arrangement with the medical superintendent, subject to the approval of the Group Officer. A record of the times when the officer attended for duty would be kept by the medical superintendent.

2. He would receive a retaining fee equivalent to one-third of the salary which had been already offered to him. This fee would cover any services rendered under the previous paragraph so long as he remained on a part-time basis.

3. Should circumstances make it necessary he would be required to resume whole-time, in accordance with the undertaking he had given, and in that event payment of the full salary would be resumed.

4. No officer who elected to go on part-time would be eligible for an allowance for board and lodging or for travelling between his home and his official headquarters.

5. Similarly, such officers, being no longer whole-time temporary civil servants, would not be entitled to official leave or to sick pay during temporary absences due to illness.

Emergency Hospital Scheme: Payments to Hospitals

In a reply to General Sir Ernest Makins on October 12 Dr. ELLIOT said payments in respect of beds reserved for air raid casualties were at present being made only to voluntary hospitals. They were made fortnightly. The total payments so far made for the first fortnight amounted to approximately £170,000. This figure would be subject to considerable adjustment in the light of additional information from the hospitals following the payments. This system enabled the country to have many beds ready and staffed for casualties which would not otherwise be available. He did not consider the provision being made against air raid casualties unreasonable. He was reviewing the list of hospitals where beds were reserved in order to ensure that beds were not being kept empty unnecessarily. Payments to the hospitals were not related to the payments normally made by civil patients, since these did not as a rule meet the whole cost of treatment. Voluntary hospitals were largely dependent on contributions and other charitable sources for the treatment of civil patients, but the Government had undertaken that the cost of treating casualties should be borne by the Exchequer. The Ministry of Health was investigating the claims submitted by hospitals to ensure that they properly corresponded with the actual additional expenditure in which the hospitals were involved by reason of the Emergency Hospital Scheme.

Income of Hospital Medical Staffs

Sir ERNEST GRAHAM-LITTLE asked on October 12 whether Dr. Elliot knew that, as the result of his action in enrolling for full-time service nearly all the medical staffs of the voluntary hospitals in London at salaries which in most cases would hardly defray their house rent, rates, and taxes, he had subjected a large number of the most distinguished members of the medical profession to acute financial stress, inasmuch as they had been suddenly prevented from earning any income from private practice, but were unable to relinquish as suddenly their heavy commitments based on their previous earnings. Sir Ernest suggested some legislative provision such as a moratorium in the payment of rent, rates, and taxes in the case of consultants thus called up for national service. Dr. ELLIOT in reply said recruitment to the Emergency Medical Service was on a voluntary basis. Salaries and conditions for this service were fixed in consultation with representatives of the medical profession. He referred Sir Ernest to the arrangements under which doctors serving in the Emergency Medical Service could go on indefinite leave, subject to recall if required, or, with certain exceptions, transfer from full-time to part-time service. These arrangements should enable the practitioners to whom Sir Ernest referred to continue private practice. Dr. Elliot added that he could not accept the suggestion of a legislative moratorium.

Hutment Hospitals

Dr. ELLIOT informed Mr. Gallacher on October 12 that in England and Wales 104 hutment hospital schemes, of 1,037 huts, comprising 38,120 beds, had been decided upon. In seventy-one of these schemes the estimate of cost submitted by a local architect had been approved and construction of the huts begun. Two of the schemes, comprising twenty-three huts, had been completed, and in several more the roofing and walling had been finished. Medical, nursing, and other personnel would be allotted to the hutment hospitals as they were completed, but he could not give the numbers. As the huts are not in use he could not express any opinion on their functioning, but had reason to trust it would be satisfactory.

Blood Transfusion Organization

Mr. CULVERWELL asked Dr. Elliot on October 12 whether the blood transfusion organization for the London and Home Counties district still took regular donations of blood from registered blood donors; and, since military requirements were provided for by a separate organization which was a special branch of the Royal Army Medical Corps, what was done with this blood given by citizens. Dr. ELLIOT replied that the blood transfusion organization for London and the Home Counties was set up to ensure a ready supply of blood. As blood could only be stored for a limited time, supplies were being continually taken from blood donors. Arrangements had been made with the Defence Services that the stores of blood would be used to supply Service requirements subject to civilian demands being satisfied. Blood which was taken and not used for its primary purpose was utilized for the preparation of serum, a stock of which was invaluable under war conditions.

Answering Mr. David Adams on the same date, Dr. ELLIOT said the chief measure taken for the increase in the supply of blood for transfusion purposes was the setting up of depots on the outskirts of the London region where a store was now always maintained. These depots had been set up by the Medical Research Council and were fully in operation. They would supply blood to the London region and to some districts outside. In the provinces the existing voluntary arrangements had been augmented.

E.M.S. and Voluntary Hospitals

On October 17 Mr. ROSTRON DUCKWORTH asked the Minister of Health whether he was aware of the view held by medical men that there was much unnecessary confusion in the relations of the emergency medical service and voluntary hospitals, and what steps he was taking to ensure smoother working and general satisfaction among those directly concerned. Dr. ELLIOT replied that some initial difficulties were to be expected in putting any large-scale organization on a war footing. His officers were in constant touch with representatives both of the medical profession and of the voluntary hospitals, and necessary adjustments were being made as rapidly as possible in the light of experience gained.

Sanitary Inspectors and the R.A.M.C.

Major MILNER asked the Secretary of State for War on October 17 whether his attention had been drawn to the dissatisfaction of sanitary inspectors at being debarred from receiving commissioned rank in the hygiene companies of the Royal Army Medical Corps, and if, in view of their qualifications and experience in sanitary administration, commissions in the above companies would in future be made available to sanitary inspectors of suitable merit. Mr. HORE-BELISHA replied that as officers of Field Hygiene Sections were called in to advise on all matters affecting the health of the troops, it was essential that these appointments should be held by specially qualified medical men so long as these were available. Major MILNER asked if Mr. Hore-Belisha was not aware that these men had high special qualifications, and if he would not reconsider the matter in view of the fact that commissions in the past had been granted to other than medical men. Mr. HORE-BELISHA said he desired to give the troops the most qualified service procurable, and for that reason commissions in the Royal Army Medical Corps were reserved for doctors. Naturally, one considered any proposals which might be made, but at the moment he could not accede to them.

Vaccination and Inoculation of Oversea Forces

On October 17 Sir FRANCIS FREMANTLE asked the Secretary of State for War if units going over-seas had been vaccinated against small-pox and inoculated against enteric fever; and if units that might be sent oversea were being so vaccinated and inoculated in readiness for over-seas service. Mr. HORE-BELISHA said that the answer to both parts of the question was, "Yes, subject to the consent of each individual." Sir FRANCIS FREMANTLE then asked if Mr. Hore-Belisha was aware that at least one unit of which he knew, and was under orders to go over-seas, was not inoculated or vaccinated. Mr. HORE-BELISHA said that if Sir Francis Fremantle would draw his attention to the unit he would investigate the matter.

Medical Attention of Scattered Defence Units.—Sir FRANCIS FREMANTLE asked on October 11 whether the War Office could arrange for the medical care of anti-aircraft searchlight men and other scattered units to be undertaken by local civil practitioners and release for other duties medical officers on the established strength who were unable to cover the ground. Sir VICTOR WARRENDER replied that the military medical establishments of these units must be maintained. Civilian medical practitioners were employed in cases which regimental medical officers were unable to attend. The ordinary arrangements were then made.

Newcastle's Milk Supply.—Mr. DAVID ADAMS asked on October 12 whether during the last two months both milk supplied under the Milk (Special Designations) Order, 1936, and undesignated milk had shown a serious deterioration when tested for tubercle bacilli by Newcastle corporation. Dr. ELLIOT replied that figures had been sent him by the corporation of Newcastle-upon-Tyne, but were not understood to relate to the presence of tubercle in the milk. He would make further inquiries of the corporation.

Doctors and A.R.P. Work.—Sir RICHARD ACLAND asked Dr. Elliot on October 12 to make every effort to reinstate doctors who gave up salaried posts for air raid precautions work under the impression they would be paid £550 a year and now found they were paid £21 a year. Dr. ELLIOT said he was not aware of any case, but if given particulars he would investigate the matter.

Disability Pensions.—On October 17 Mr. PRITT asked the Minister of Pensions whether he would arrange that every soldier proceeding on active service should be furnished with a document setting out in simple language his rights to receive a disability pension in the event of his being wounded or injured, or falling sick. Sir WALTER WOMERSLEY said he understood that the Royal Warrant in its complete form was to be issued with Army Orders. Article 5 of the Royal Warrant would be construed in a liberal spirit in the light of the expert guidance which would be given by medical officers of very great experience, and would ensure that no material evidence in support of a claim was excluded from consideration.

Medical Students in the Army.—Arrangements have been made for the release from the Army of medical and certain other specialist students provided that they have reached a sufficiently advanced point in their studies. The case of students between 18 and 19 years of age will be considered.

Discharge of Mental Hospital Patients.—The number of persons who were discharged to their homes from mental hospitals under the Emergency Hospital Scheme does not exceed 200. No patient was discharged unless selected after careful investigation of all relevant circumstances, including his home conditions, as suitable to be cared for and supervised by his relatives at home. The Board of Control is reviewing the arrangements for the care and supervision in war time of individuals living in the community who are suffering from mental disorder.

Notes in Brief

In the first nine months of this year 527 persons were killed by accidents at mines under the Coal Mines Act and 2,221 seriously injured.

EPIDEMIOLOGICAL NOTES

Infectious Diseases during the Week

Small increases in the incidence of scarlet fever, diphtheria, and pneumonia (primary and influenzal) have been recorded; although the total incidence of these diseases was much lower than in the corresponding week last year, the rate of increase of all three diseases was comparable in the two years. It is too early to say whether the observed increases are entirely attributable to seasonal influences or are in part due to the re-evacuation of a number of susceptibles back to the large centres of population. Probably little effect in this direction need be anticipated until the schools are reopened generally. It is sufficient to note at this stage that despite the abnormal environmental circumstances of the evacuees and the inevitable disorganization of medical and nursing services, there have been no serious outbreaks of infectious diseases in the reception areas, although the presence of diphtheria carriers gave rise to anxiety in some of them.

Typhoid Fever in 1939

In Europe and the United States of America the situation as regards typhoid fever has remained satisfactory during the first eight months of 1939. Morbidity in most of the countries was about the same as in the corresponding period of 1938 and much lower than in 1937. In the Scandinavian countries and in England the figures were appreciably lower than in 1938. In this country, despite a rise from 96 to 267 during the four-week period ended September 9, notifications have remained well below the median value for the corresponding weeks of the eleven years 1927–37. In France and Germany the total incidence was below the median values, but in Poland the median was exceeded during the two four-week periods ended August 12.

There was little change in the general mortality rates, as in the morbidity rates, in Europe in 1938 compared with the preceding year. As in previous years the highest rates were recorded in Portugal 17 (17.9) per 100,000 population, Malta 6.4 (10.3), Rumania 6.2 (8), Hungary 5.9 (10), Czecho-Slovakia 5.2 (6.3), Lithuania 4.9 (5.5), and Bulgaria 4 (5.8). Rates below 4 per 100,000 population were reported in Poland, Yugoslavia, Greece, and Turkey. (Figures in parentheses refer to the preceding year.)

Twinning in Marmosets.—In forty pregnancies in marmosets twins occurred in 87.5 per cent. In seven instances the sexes of the twins were: two pairs male; two pairs female; three pairs heterosexual. These observations confirm the findings of Hill that two blastocysts fuse completely in early presomite stages, with breaking down of the conjoined chorionic wall, and the formation of a common chorion containing two embryonic primordia. Anastomotic connexions between the umbilical and the placental vessels of the two embryos are established very early. Nevertheless, examination of the gonads and external genitalia of opposite-sexed pairs of foetuses reveals no evidence of freemartin effects.—Observations on Twinning in Marmosets. G. B. Wislocki.—*Amer. J. Anat.* May, 1939, 64, 445.

No. 39

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended September 30, 1939.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1939					1938 (Corresponding Week)

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS.—All communications should be addressed to the Advertisement Manager (office hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are
EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London*
SECRETARY, *Medisecra Westcent, London.*

The address of the B.M.A. Scottish Office is 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh), and of the Office of the Cumann Doctúirí na h-Éireann (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone 62550 Dublin.)

QUERIES AND ANSWERS

B. coli Infection of Kidney

DR. C. S. STORRS (Helston, Cornwall) writes: A young married woman, seven months pregnant, had an attack of *B. coli* infection of the kidney in May. She was acutely ill for forty-eight hours with temperature 103°-104.5°, rigors, and pain in left loin. *B. coli* were present in the tissues. She rapidly recovered under proseptasine. The urine was free from *B. coli* in ten days. At the end of September she had another similar attack. She now asks whether anything can be done to prevent recurrence of these attacks. What can I do about it?

Income Tax

Payment for A.R.P. Lectures

"ASSISTANT M.O.H." has received £8 8s. for first-aid lectures given in 1938-9. How should such fees be assessed?

*** If he were in general practice the fees could be regarded as part of his general professional earnings assessable under Schedule D, but as his existing assessment is under Schedule E in respect of a specific appointment the fees in question must be separately assessed. On that basis they have to be regarded as a new source, and the amount received for work in 1938-9 is chargeable to tax for that year.

LETTERS, NOTES, ETC.

The Aggressive Instinct

Mr. FAUSET WELSH, F.R.C.S., writes from Birmingham: Without being psychotherapists, quite ordinary persons can see the sound sense in Dr. B. H. Kirman's letter in the *Journal* of September 30 (p. 701). For an adult to give direct expression to normal aggressive instinct is, he says, pathological in a civilized community. Can those, then, who in good faith encourage this instinct be sane? Have we not as a profession the obligation to proclaim the correct psychotherapeutic treatment for the disease whether manifested in individuals or communities? Can we not concentrate on preventing and treating disease rather than on preparing elaborate plans against conditions which the same plans must encourage? Some soldiers dislike being bombed and object. Many more civilians will dislike it still more and object more strongly. It seems a reasonable attitude, and attempts to discourage this dislike by encouraging normal aggressive instinct are either childish, pathological, or uncivilized. Surely the rational principle of treating psychological casualties includes removal of the cause if still operative. If we support or encourage this cause we are betraying our trust, and our treatment will be ineffective or productive of further evil. As we are fighting against moral evil medical men and particularly psychologists should know what sort of weapons are likely to be most effective in both attack and defence.

The Flight from Poland

Tragic stories of the flight from Poland are told in a dispatch just received in London, by way of Budapest, from the administrator of the Save the Children Fund in charge of relief work among child refugees near the Polish-Hungarian frontier. Many of the refugees began their flight in the early days of the war, when they escaped from areas overrun by the German armies into territory then still in Polish hands. Then came the Russian invasion and they were again put to flight. For the most part they had to hide in forests during the day, lying on the ground while bombing from the air was going on. Then, at night, they would continue their journey, ill clad, hungry, and with only the smallest remnants of their possessions that they could carry with them. "The psychological effect on the children is terrible," says the Save the Children Fund administrator, who is a psychologist. "They are still in the grip of terror when they come over the frontier to us." As the Fund workers go round the camps, almost every refugee holds out a piece of paper bearing the name of some child, or mother, or husband, who has been lost in the flight. Winter has set in abnormally early in Hungary this year and the refugees are suffering severely from lack of clothing. Most of them set out in what they were wearing at the time, with no change of garments. The Fund is supplying the children with shoes, and with warm sweaters and stockings. It is also distributing flannel which the women can make up into garments for their children now that they have reached the safety of refugee camps. All sections of the Hungarian people are showing great practical sympathy with the refugees, adds this correspondent, and the Winter Relief Fund, of which Madame Horthy, wife of the Regent, is president, has diverted a proportion of its stores, intended for the Hungarian poor, to aid the refugee children. The Save the Children Fund (20, Gordon Square, London, W.C.1) has also begun the distribution of relief to refugees who have found their way into Rumania. In Lithuania the holiday camp of the "Ose" Committee, which is working in connexion with the Fund, has opened as a home for refugee children.

Hair Dyes and Hair Dyeing

Mr. STANLEY REDGROVE continues to unveil to the public the secrets and mysteries of modern cosmetics. The first edition of *Hair Dyes and Hair-dyeing Chemistry and Technique* appeared in 1929 under the title of *Blonde or Brunette.* It is now revised for the second time in collaboration with an expert hairdresser, Mr. J. Bari-Woolls. It is not primarily written by any means for the medical profession but rather for practical hairdressers. Nevertheless, it is a subject that medical men, and especially dermatologists, are frequently consulted about, and if they read this volume they will at all events be better enabled to disguise their ignorance of the subject; they will find the whole question of dyes and dyeing dealt with from a strictly scientific point of view, and will be able to advise their women patients as to what processes it is wise or not for them to submit to at the hands of the hairdresser. We would particularly advise medical men to read the chapter devoted to "para," which is the trade name of paradiaminobenzine or paraphenylenediamine, which is so satisfactory as a hair dye from the cosmetic standpoint that its popularity persists notwithstanding its dangerous properties. Mr. Redgrove says that the ideal hair dye must be perfectly harmless but produce permanent colours equal to those of Nature, and must be easy to apply. It must not render the hair unresponsive to permanent waving, and it should consist of two or three solutions of such a kind that by adjusting the proportions of each any and every possible shade should be produced. We need hardly say that such a dye has not yet been discovered. The book is published by Heinemann at 10s. 6d.

The Canning of Food

A well-produced pamphlet entitled *Canned Foods* has been prepared for the use of domestic science teachers and students by the Canned Foods Advisory Bureau, 243, Regent Street, London, W.1. Members of the medical profession can obtain copies on application to that address.

LONDON SATURDAY OCTOBER 28 1939

PROPHYLACTIC IMMUNIZATION AGAINST MEASLES, SCARLET FEVER, DIPHTHERIA, WHOOPING-COUGH, AND INFLUENZA*

BY

SIR J. C. G. LEDINGHAM, LL.D., D.Sc., F.R.C.P., F.R.S.

Director, Lister Institute, London; Professor of Bacteriology, University of London

The prevention of infectious disease by active immunization methods is no new thing, and I am going to assume that what is chiefly wanted at the moment is some reassertion and fortification of the scientific background of these procedures and some account of their achievements in the field, with a view to rendering them more acceptable to those responsible for the conservation of child life in this country and thus to facilitate much-desired propaganda on the large scale. Whatever may be the reasons—and I hope to suggest some later on—there can be no doubt, I think, that in the field of prophylaxis of the kind we are considering to-day this country has, in the main, been a follower, and, I'm afraid, rather a tardy follower; for, though our laboratory workers have contributed very materially to the knowledge of methods, we have left to other countries the task of trying them out seriously and intensively in the field.

The safety of any method to be applied to man must always be a prime consideration. There must be no risk to life, and even the minor inconveniences, local and general, incidental to the introduction of a prophylactic through the skin must also, so far as possible, be reduced to a minimum consonant with the effectiveness of the product. In the course of securing these desiderata—and I refer here particularly to the diphtheria prophylactics—there have been in the early period of their use, though not in this country, some very few unfortunate experiences that could not have been foreseen at the time but which further experiment explained and taught us to avoid in future. With the introduction of the Therapeutic Substances Act, however, such accidents should never recur if the prescribed rules for the preparation and testing of prophylactics for issue are carefully carried out, and also if those responsible for administering them perform their duty intelligently. We have now the definite assurance that the prophylactics we are here considering are both safe and potent, and, when administered with the care and circumspection that proceed from knowledge, are calculated to cause only quite negligible inconvenience to the subject inoculated.

Diphtheria

Of the five infectious diseases with whose prevention by prophylactic inoculation I am dealing, diphtheria undoubtedly merits chief consideration because we now know quite definitely from field trials in other countries that intelligent and persistent immunization of the child population, starting with the pre-school child one year old, can bring the diphtheria morbidity down to zero. Indeed, as that great pioneer in this field the late Dr. W. H. Park remarked at the International Congress for Microbiology in London in 1936, "The control of diphtheria by specific treatment and specific prophylactic immunization is one of the most gratifying victories of bacteriology." Let me just enumerate some of the landmarks in the history of this matter.

In 1889 Roux and Yersin demonstrated that the diphtheria bacillus elaborated a toxin, and that to this toxin was due the symptom-complex of diphtheria. This led in the first instance to Behring and Kitasato's great discovery of antitoxin in 1890 and to the treatment of diphtheria by passive immunization methods still current and without a rival. The use of diphtheria toxin for preventive purposes was also early foreshadowed, but many years had to pass before the time became ripe for exploring the possibilities of active immunization in diphtheria control schemes. The Schick test, introduced in 1913, gave us most valuable information regarding natural or naturally acquired immunity to diphtheria at various age groups, and now that we have that knowledge we can to a large extent dispense with it, particularly in dealing with young children. It still, however, has its uses as a guide to prophylactic immunization in the older age groups, in which the proportion of Schick-positive persons steadily diminishes owing to increasing opportunities of acquiring immunity through, it is believed, mild or unrecognized infections contracted from their surroundings.

Then came the era of preventive control by partially neutralized mixtures of toxin and antitoxin. Behring introduced these for human use in 1913, and Park and his colleague Zingher exploited them very successfully in New York during the period 1915–23. These partially neutralized mixtures were not ideal immunizing agents, as they were of doubtful stability and their safety was not easily controlled owing to dissociation phenomena under different conditions of storage which I need not go into. They left much to be desired for acceptable propaganda purposes, but nevertheless when administered by good hands and prepared with the necessary care they did excellent service and showed conclusively what could be done in this way to transform a condition of susceptibility into one of more or less solid immunity.

---

* Read in opening a discussion in the Section of Medicine at the Annual Meeting of the British Medical Association, Aberdeen, 1939.

The Introduction of Formol-toxoid

The next notable advance was the introduction of modified toxin or toxoid for prophylactic use. Glenny and Südmersen in 1921 recorded the fact that toxin which had been converted into an atoxic product by contact with formalin was capable of immunizing guinea-pigs against diphtheria toxin. Ramon of the Pasteur Institute who in 1922 published the first of an important series of papers on the flocculation that took place in neutral mixtures of toxin and antitoxin, and thereby provided immunologists with an *in-vitro* method of titration, extended his observations to formol-toxoid, or, as he called it, "anatoxine," and found this to behave similarly, showing that its power of combining with antitoxin was unimpaired. In 1924, we are told, he inoculated himself with "anatoxine," and in subsequent years he did much to popularize its use in France and other countries, particularly America. In an address on world experience of formol-toxoid at the jubilee celebrations of the Pasteur Institute last March, Ramon stated that more than three millions have now been vaccinated in France, while in Canada, of a population of ten millions, more than two millions have been immunized. The new antigen was immediately exploited by Park in New York, and by 1935 one million had been immunized in that city. In Paris since 1928 some 50 per cent. of Parisian children have been immunized, and deaths from diphtheria fell from 318 in 1928 to seventy-two in 1938. In December, 1931, it became obligatory to immunize the French soldier against diphtheria and enteric by the use of a mixture of "anatoxine" and T.A.B. vaccine, and since that time tetanus toxoid has been added to the mixture. By the end of 1938 some 800,000 troops had been so vaccinated, and Ramon was able to state that clinical diphtheria was disappearing from the French army. He bemoaned the fact, however, that civilian France, which depended so much on the conservation of its child population, was still too apathetic in the matter of diphtheria immunization, and he looked forward to this procedure becoming obligatory in the civil population. This, I understand, is now the case.

The most arresting figures are gleaned from Canada, where efforts to popularize the immunization of children, on whom diphtheria exerts its worst toll, have been most intense and persistent. Some towns and rural districts in Canada have 70 to 90 per cent. of the child population vaccinated. The experience of the city of Hamilton (150,000 population), which was the first city of this size to attempt to control diphtheria with formol-toxoid, is widely quoted, for no deaths from diphtheria have occurred there since 1930 and no case of diphtheria since 1933. In Toronto, with a population of 650,000, some 104,000 infants have been vaccinated since 1926, and the diphtheria incidence fell in the four years 1930–4 from 164 to 3.5 per 100,000. In 1936 there were only forty-eight cases and two deaths. In New York in 1936 some 75 per cent. of the infant population had been vaccinated. Round about 1924 this city had annually some 10,000 cases of diphtheria with 700 deaths, but in 1936 the cases had fallen to 1,143 and the deaths to thirty-five (or about 0.47 per 100,000 inhabitants. In 1938 the reported cases fell to only 163 in this great city.

It is only when the proportion of vaccinated children reaches 70, or 80 per cent. that, as Ramon says, one sees the real fruits of one's work in a great reduction of the diphtheria incidence, perhaps to zero. We have nothing like this to show in Great Britain. In trials hitherto made in this country the value of prophylactic vaccination against diphtheria can be measured only by the relative immunity of the vaccinated groups as compared with that of the unimmunized. These data are arresting enough, so arresting indeed as to render urgently desirable the immunization of all pre-school children from the age of one year, with a view to the ultimate extinction of this disease from the community. No other method of diphtheria control can offer such prospects. What is the problem in this country?

Our Need of More Intensive Propaganda

The chief medical officers of the Ministry of Health and of the Scottish Board of Health both emphasize the necessity for more intensive propaganda, for the diphtheria incidence remains high and almost stationary. In England and Wales there have been annually some 60,000 to 70,000 cases of diphtheria, with some 3,000 to 4,000 deaths, and in Scotland some 10,000 cases, with 400 to 500 deaths. Sir Arthur MacNalty in his report for the year 1937 informs us that Chester, with 45 per cent. of its children vaccinated, "is probably the best-immunized town in the country." After it come Birmingham, Walsall, Worcester, Leeds, Manchester, and Chatham, "all of which are in the neighbourhood of 35 to 40 per cent." London occupies an unenviable position at the bottom of the list with only some 5.3 per cent. of its child population immunized.

To illustrate what can be done by less intensive or, more correctly perhaps, less effective propaganda so far practised in this country, I may cite briefly from current reports the experiences of the city and county of Aberdeen and of the city of Birmingham. During the period 1935–7 some 16,000 of the 25,000 children on the school rolls in the county of Aberdeen have been immunized, together with some 3,000 to 4,000 pre-school children, the antigen employed being alum-precipitated toxoid (A.P.T.), given by what has come to be known as the one-shot method. It is interesting to note that the parents' consent was obtained for about 80 per cent. of the children attending the county schools, a result most creditable to the intelligence of the Aberdeenshire parent. What has been the effect of this crusade? Among the immunized children there have been since March, 1935, seventy-three notifications of diphtheria, giving an attack rate of 26 per 10,000 children, while among the unimmunized, including some 3,000 known Schick-negatives, the attack rate was 251 per 10,000, or ten times that among the immunized. In the city of Aberdeen active immunization of school children and those of pre-school age began in September, 1936. Unfortunately, parents' consent was difficult to obtain, and only 52.3 per cent. of new school entrants were immunized. During the period September, 1936, to March, 1938, 3,596 children were immunized, of whom fifteen contracted diphtheria, giving an attack rate of 0.4 per cent., whereas among the non-immunized the attack rate was 1.5 per cent., or nearly four times that among the immunized. There were no deaths among the immunized, and the disease was mild.

In the city of Birmingham an immunization crusade was started in 1925, the agent used being toxoid-antitoxin mixture (T.A.M.) in three doses of 1 c.cm. at fortnightly intervals. Those completely inoculated under the age of 15 in 1938 numbered 96,446, or some 42 per cent. of the total population in that group. As for the pre-school group under 5, about 27 per cent. had been immunized by the end of 1938. The total cases of diphtheria in the last five years have varied from 1,019 to 1,359, and the deaths from sixty-three to eighty-four annually. Only fifty-six cases in all have occurred among the inoculated children, and there have been no deaths.

It is quite clear from these illustrations that it will be necessary to increase greatly the percentage of those immunized before evidence is obtained of any material fall in the general diphtheria incidence.

The Antigens and their Administration

Now let us consider as briefly as possible the problem of antigens and schemes of administration appropriate to each. The Chief Medical Officer of the Ministry of Health remarked in a reference to this subject in his report for the year 1937: " It is unfortunate that the exact technique, preparation of vaccine, and method of administration are still matters of medical controversy. It is probable that the lack of a general standard has militated against the more general adoption of anti-diphtheritic immunization in this country." I would consider this a rather unfortunate statement. Though admittedly there is no general standard, the lack of one has been an advantage rather than otherwise, for it has stimulated valuable comparative field trials, and for several years now we have learnt to know more than one type of antigen which, when administered appropriately, is capable of reducing diphtheria incidence materially. Progress has been impeded by many factors, and not least by what a recent leader writer in the *Journal* calls that "doltish prejudice," not confined to any one social or intellectual stratum, which is fostered by anti-social societies posing as the protagonists of liberty. When liberty becomes anti-social and impedes the application of scientific truth to the improvement of human well-being then I think some form of compulsion is the only remedy, though one might hope it would be merely temporary, pending the wider diffusion of scientific knowledge in the community. I might add that I should have liked to see a far more encouraging lead on the part of health authorities generally, from the Ministry of Health downwards, while giving all credit to those enlightened health authorities who have tried their best.

We have at least four antigens which we know to be potent—namely, F.T., T.A.F., A.P.T., and T.A.M. F.T., or formol-toxoid, has done marvellous service in France, Canada, and the United States, though in the latter country A.P.T. is now largely used, while T.A.F., or toxin-antitoxin floccules, A.P.T. (alum-precipitated toxoid), and T.A.M. (toxoid-antitoxin mixture) have been more popular in this country. The general tolerability of these antigens undoubtedly differs, although possibly some workers with large experience have laid more stress than others on the expediency of guarding against unusual reactions during immunization by performing preliminary detector tests. The Canadian workers who have used F.T. for the most part emphasize the value of Moloney tests, particularly in older children and adults, while in France the matter of unusual reactions with the same antigen has not been greatly stressed.

T.A.F. and T.A.M. are relatively innocuous at all ages, while A.P.T. is well borne in young children. In older children and adults it may give rise to painless nodes, which take some time to disappear. A.P.T., by virtue of the slowness of absorption of the antigen and consequent longer stimulus to the antibody-forming mechanism, can give rise, as Glenny, who introduced it, showed, to a considerably higher antitoxin titre, given in a single dose, than any of the other antigens. For this reason it may well become the antigen of choice for young children, the group we wish above all to see in course of time fully immunized, and there is now a consensus of opinion that no countenance should be given to the use of this excellent antigen in any one-shot method.

Antigenic Values Compared

Fitzgerald and his colleagues have tested on batches of children the comparative value of three doses of F.T., two doses of F.T., one dose of A.P.T., and two doses of A.P.T., and have concluded from the results of actual antitoxin titrations that three doses of F.T. give a superior, but not a greatly superior, immunity to that given by two doses of A.P.T. Two doses of F.T. or one dose of A.P.T. yielded by comparison very poor results. On the other hand Volk and Bunney (1939) found that two doses of A.P.T. given at three weeks' interval were superior to three doses of F.T. at similar intervals.

There is no doubt that it is highly expedient that comparative trials should still go on, for it is desirable in planning extensive crusades to determine what form of antigen and what scheme of administration are best calculated to yield the most lasting immunity, due consideration being always given to the tolerability of the antigen or antigens in the interest of acceptable propaganda. On this point Volk and Bunney make a very pertinent remark: "The ultimate basis," they say, "for evaluating a particular scheme of immunization is whether it protects against diphtheria or not, and not whether it confers Schick-negativity or raises the antitoxin level to any definite point." Further, they remark that, "It is entirely possible that a procedure which results in a lower level of antitoxin than some other may still be the method of choice from the public health standpoint—that is, it might be less expensive, easier to administer, and confer a high enough percentage of immunity to be the most efficient use of the public health dollar in prevention of diphtheria."

In an important study by Jones (1938) the comparative value of F.T. and A.P.T. was tested on guinea-pigs, which after immunization were bled every four weeks for a period of thirty-two weeks, their sera being then tested for antitoxic value. This study emphasized the importance of lengthening the interval between the first and the second dose in a two-dose system. He found A.P.T. to be an excellent primary immunizing agent, and he suggested that if an adequate interval elapsed between the first and the second dose it mattered little which type of toxoid was used for the second or later injections. Whether F.T. or A.P.T. was used, it was important that the dose should contain at least 15 Lf. The interval between doses should in his opinion be prolonged to two months or even longer. It may be noted that in the immunization of horses against tetanus or diphtheria toxins the importance of a lengthy interval between the primary and secondary stimuli is well recognized.

I may here summarize for purposes of discussion the main points on which there is already fairly general agreement:

(1) A single immunizing dose of any antigen is not effective if high and lasting immunity is desired, and, where still used in certain localities, should be abandoned. (2) A.P.T. is *per se* a very significantly more effective reagent than F.T., and if the scheme adopted involved two doses only, then two doses of A.P.T. would give higher levels of antitoxin than two doses of F.T. (3) Any one of the three methods in common use—namely, three doses of T.A.F., three of F.T., or two of A.P.T.—will greatly reduce the diphtheria incidence among the inoculated. Further, as A.P.T. is the most effective antigen and is easily tolerated in children under 8, it may be recommended for the primary stimulus and followed at

not less than one month's interval by two doses either of T.A.F. or F.T. Whether to stick to the same antigen throughout is a matter for discussion. (4) With the knowledge that any one of these systems can be guaranteed to reduce incidence, local health authorities contemplating crusades can still provide useful comparative information by employing two different schemes, probably in alternate children. (5) There is general agreement that longer intervals between doses, and specially between the first and the second dose, are calculated to yield superior results. (6) At the start of a crusade in any community children from infancy to school-leaving age should be immunized in the largest possible numbers. (7) As time goes on immunization would be confined to the pre-school children of 1 to 2 years, and when such children go to school it may be very desirable to give a single reinforcing injection. (8) In children over 10, T.A.F. is to be preferred to F.T. or A.P.T. unless preliminary detector tests are performed. (9) Not until some 80 per cent. of the child population under 15 have been immunized will a material decrease in the incidence rate of diphtheria be realized.

Whooping-cough

I pass now to whooping-cough, which, with a death rate per 1,000 population of 0.043 (England and Wales, 1937), comes next to diphtheria, with a corresponding rate of 0.072. In England and Wales 1,750 deaths from this disease were recorded in 1937, practically all in children under 15. In Scotland in 1938 some 6,000 cases were reported, with 111 deaths of children under 1 year and 105 in the age group 1 to 5. As a killing disease of infancy, therefore, whooping-cough closely rivals diphtheria, and undoubtedly its prevention or control by active immunization methods is a challenge to us all. The prospects of such control, in so far as we may judge from results of crusades of quite recent years, particularly in the United States, are now certainly bright, and there is every reason why health authorities in this country should promptly organize immunization schemes on sound lines, with a good prospect of reducing the incidence of whooping-cough among vaccinated children definitely exposed to this highly contagious and distressing infection.

The aetiological agent of whooping-cough is recognized to be the *Haemophilus pertussis*, originally discovered by Bordet and Gengou in 1906. In recent years valuable bacteriological work has been accomplished in identifying this organism in the early catarrhal stages, when it may be found in some 80 per cent. of cases by the cough-plate method, and also in diminishing percentages as the weeks pass. It is a fortunate thing that the organism is a single antigenic type, for it makes immunization by vaccine far more practicable; but it is also most important for immunization purposes that only smooth freshly isolated and virulent strains be chosen, as artificial passage of the organism on unsuitable media is accompanied by degradation of the efficient antigen and by loss of virulence. It is highly probable that failure to choose strains of full antigenicity for vaccine purposes accounted for conflicting results in some of the earlier trials in the past decade, and that there has also been a failure to follow up carefully the degrees of exposure to this disease not only of the vaccinated but also of the control groups. I propose, therefore, to sketch one or two only of some quite recently recorded crusades which were embarked upon with great care and carried out in the most thorough and painstaking manner.

Studies on Whooping-cough Immunization

Kendrick and Eldering's study (1939) was made in the city of Grand Rapids, Michigan, with a population of about 168,650. 1,815 children between 8 months and 6 years were fully vaccinated with thoroughly tested strains from cough-plates, seventy-two-hour growths being washed off the medium, filtered through cotton-wool, and then centrifuged. The deposit was suspended in saline containing 1 in 10,000 merthiolate or 0.5 per cent. phenol and stored till sterile. It was standardized to 10,000 millions per c.cm., and the standard scheme was 4 doses at weekly intervals of 1 c.cm., 1.5 c.cm., 1.5 c.cm., and 3 c.cm. Some local soreness and induration resulted, but systemic reactions were slight or absent. The controls numbered 2,397, and observation was made over a period of forty-four months—March 1, 1934, to November 1, 1937. These 4,212 children were at risk for an average period of 13 months per child, 15 months in the vaccinated group and 11.6 months in the control group.

For any number of vaccinated children in a district a like number of controls were chosen in the same area, and as providing evidence of equality of exposure, both groups, we are told, had a very similar experience with such diseases as measles and scarlet fever.

The follow-up entailed 23,961 visits, or 5.7 visits per child at an average interval of 2.3 months. In 69 per cent. of the children in the vaccinated group, cough-plates were made in accepting the diagnosis of pertussis, and also in 67 per cent. of those in the control group. It is of considerable interest that, in those of the vaccinated group who contracted pertussis, cough-plates were positive in 6 per cent. as against 24 per cent. in the control group.

The results were impressive: 400 attacks occurred in all—namely, fifty-two in the vaccinated group and 348 in the control group. As to the type of attack, "severe" cases formed only 3.8 per cent. of the total in the vaccinated group. In the control group they constituted 13.1 per cent.

Statistically investigated in relation to exposure, the results showed that 12.8 per cent. of exposures in the vaccinated group were followed by pertussis, as compared with 68.5 per cent. in the control group. I may add that this investigation entailed the services not only of the Michigan Board of Health with its Bureau of Laboratories but also of the City Health Department of Grand Rapids, with its health officer and school physician. Local doctors helped in the immunization clinics, and assistance was given by nurses from the Bureau of Public Health Nursing of the City Health Department.

As a corollary to this field trial I would mention a most interesting experiment by Lawson (1939), who attempted to evaluate in mice the prophylactic value of various pertussis vaccines prepared from smooth, rough, and intermediate strains, the test of immunity being the capacity of the immunized mice to withstand an intratracheal injection of 0.05 c.cm. of a virulent culture calculated in the controls to produce a pertussis pneumonia. The results showed great differences in the immunity following vaccination with the various types: 92.6 per cent. survivals occurred among those vaccinated with the smooth strains, while those immunized with the intermediate and rough strains had only 30.8 per cent. and 7.1 per cent. survivals respectively.

One final study reported by Miller and Faber (1939) is worthy of note. This study on whooping-cough immunization was made at a baby clinic in California. Every month a number of infants less than 1 year old were vaccinated with pertussis vaccine given in three doses of 20,000 millions, 30,000 millions, and 30,000 millions at weekly intervals, while a similar number were selected by chance as controls. The vaccine was made from smooth Phase I organisms grown on Bordet-Gengou medium with human blood added. In all, 211 children were vaccinated and 182 acted as controls. All exposures were carefully noted, and, throughout an observation period of two and a half years there occurred among the test group twenty-six exposures which were followed by nineteen escapes, and among the controls twenty-five exposures with three escapes. The "communicability" rate among the vaccinated was therefore only 26.9 per cent., as against 88 per cent. among the controls.

Apart from the results achieved in these trials, which I can only sketch here, the mere reading of the records gives one a lively impression of the courage of the organizers and their determination to probe the possibilities of a method of prophylaxis against whooping-cough in spite of early failures by others, and to endeavour to find out to what factors, whether concerned with the vaccine and its administration or with the interpretation of the resulting data, such failures were most probably due. There is no doubt that a correct evaluation of the method can be made by an organization capable of observing as precisely as possible the exposures of the test and the control subjects and noting the proportion of escapes in the two groups.

Another problem arises here. The age at which a pre-school child, say 9 months, may be submitted to immunization against diphtheria is also the age at which this same child might very desirably be immunized against whooping-cough. What is to be done? I am not aware that diphtheria toxoid has so far been administered in combination with a pertussis vaccine, but I see no reason why this should not be attempted if Ramon's claim holds that the potency of diphtheria toxoid in mixture with T.A.B. vaccine is in no way interfered with and indeed appears to be enhanced. Such mixtures would first require to be tested on animals in which, at any rate, the rise in antitoxin titre can be accurately evaluated.

Before, however, we can embark seriously on well-planned crusades to prevent diphtheria and whooping-cough, one great stumbling-block has to be got rid of, and it is not the stumbling-block of general apathy. It is the stumbling-block occasioned by the fact that many large health authorities either cannot afford or are not sufficiently alive to the necessity for trained whole-time bacteriologists on their staffs capable of organizing and co-operating in such crusades. It is a short-sighted policy to which the Ministry of Health might well direct its attention, because, if persisted in, we cannot hope to keep pace in this country with the progress in preventive medicine registered elsewhere.

Scarlet Fever

With regard to scarlet fever, I think it is fair to say that even if a thoroughly dependable scheme of vaccination with the appropriate streptococcal toxin, the strength of which is measured in skin-test doses, could be recommended and put in practice, the mass immunization of children would not appear to be particularly urgent in view of the benign character of the malady in these days. In the United States the position is similar, and no active immunization against scarlet fever seems to be taking place, though both here and in that country much has been and still can be successfully done to protect nursing staffs and others in institutions. This limited application of the method of active prophylaxis has undoubtedly resulted in a reduced incidence of scarlet fever. A few months ago the Surgeon-General reported to the Office Internationale in Paris that active immunization against scarlet fever had made little progress in the United States, and he gave as reasons: (1) the benign character of the malady; (2) indecision as to the practical value of the method; and (3) the limitations imposed on production of the antigen by holders of the Dick patent. The decision of the Ministry of Health not to give its blessing to the practice of prophylactic immunization against scarlet fever, at least under present circumstances, would seem to be justified, and I do not propose to say anything more about it.

Measles

The possibility of preventing measles or of mitigating its attack by passive immunization of contacts with convalescent measles serum or, it may be, of adult serum, has been recognized for over twenty years, and the method has been practised extensively, but less perhaps with the object of preventing attack than of moderating possible attacks on weakly children who happen to be contacts. A considerable amount of success has been achieved in both directions, but there has been no widespread effort to secure and store the human sera necessary for more than a small proportion of contacts, so that, as a measure calculated to reduce epidemic incidence, it plays only a very minor part. It is unnecessary for me to enlarge on the technique and practice of the method, and I shall therefore content myself with referring briefly to certain difficulties and problems that have arisen in connexion with large-scale experience. In this country the London County Council has during the past decade devoted much attention to measles prophylaxis, and has published elaborate accounts and analyses of its experience both with convalescent and with adult sera. Gunn (1938) in a recent account of experiences during the London measles epidemic (1935–6) draws attention to the fact that there is no method of assaying beforehand the potency of a particular batch of human serum. It is probable, as he says, and as we know for certain in the case of convalescent poliomyelitis serum, that potency may vary greatly and may account for disappointing and anomalous results. Measles prophylaxis by the passive method cannot in his view be greatly extended in scope until immune serum is readily available at all times when required and until deliberate exposure is practised so that non-immunes may have the advantage of attenuation. This, as he says, can be justified only if the efficacy of the serum is proved beforehand and parents or guardians give their consent.

Dr. Gunn raises the question whether the possibilities of active prophylaxis, or of combined active and passive prophylaxis, may not reasonably be exploited further. To use for purposes of active prophylaxis infective material from measles in the early catarrhal stage, as some have on occasion done, would, I am afraid, be a dubious and impracticable expedient. We must wait for further knowledge of the infective agent of measles, and it is slow in coming. The stumbling-block in experimental research on measles has been the difficulty of transmitting the disease with certainty to any laboratory animal and carrying it on in passage. If this could be achieved we would be in a position not only to assay batches of convalescent or adult serum but also to explore the possibilities of active prophylaxis.

Influenza

Influenza, and by that I mean more specifically influenza as we know it in epidemic times, is now recognized to be a virus disease communicable to more than one laboratory animal and capable of being passaged with regularity in such, as well as in the embryo chick membranes. We are therefore in an excellent position to explore in man the possibilities of active prophylaxis, and extensive research to this end is in progress in this and other countries. The position at the moment has been clearly stated by Andrewes (1939) in a recent paper. We now know that active or "living" virus when introduced subcutaneously or intraperitoneally in large doses can protect ferrets from contracting infection by contact and also inhibit the development of lung lesions, but that it does not usually protect them against a test dose of virus administered by the nasal route. When the inactivated virus is introduced subcutaneously in ferrets and mice it will immunize, though less effectively than the "living" virus. Fairbrother and Martin (1939) have shown that elementary-body suspensions obtained from pneumonic lungs of mice, when heated at 57° C., are highly satisfactory immunizing agents for mice when tested for immunity by the nasal route. Both "living" virus and inactivated virus, given subcutaneously to man, induce the development of specific virus-neutralizing antibodies in the blood serum.

One finding, however, which is likely to complicate the problem of active immunization as applied to man is the multiplicity of antigenic types among the strains recovered from different outbreaks of human influenza. These types do not differ so sharply from each other as do the pneumococcus types; but there would appear to be at least four main types, together with others, or master-strains, which contain in themselves most of the major antigens and react, therefore, with the immune sera evoked by all strains isolated from human influenza. The problem raised by this complication, and its bearing on immunization of man as a practical issue, has been dealt with by Dr. Stuart-Harris, who has had especial experience in this sphere of work. Fairbrother and his colleagues claim that these antigenic differences, which are brought to light by the use of the virus-neutralization test, cannot be detected when the complement-fixation test is used, and they suggest that the basic antigen may possibly be identical in all strains. Doubtless research on this problem will be continued with the intensity its importance demands, and we may reasonably hope that some really useful addition to our armamentarium against influenza may emerge.

Conclusion

To conclude, I have written almost entirely from the standpoint of one who has had little opportunity of observing at first hand the difficulties inevitably encountered in attempting to apply effectively results of laboratory research that can be guaranteed to reduce the incidence and mortality of certain of the diseases here discussed. I can appreciate these difficulties, however, and can only regret that what may be called the social impact of medical discovery in the field of prevention takes so long to fructify. In the field of treatment discoveries get across quickly enough, perhaps too quickly. When I reflect that, owing to ignorance, vested interest, or complacency in high places, a municipality is still prevented from ordering the pasteurization of all milk that comes into it, I sometimes despair of getting preventive science across. If a move was made to make diphtheria immunization compulsory, as it is now in Guernsey, we would be told, I suppose, that the Government cannot move in advance of public opinion. In reply I would say that the present time of national stress is rather a favourable one in which to change that policy, and to impose on people what is good for them if they are unable to realize what is good for themselves and their children. It may sound a totalitarian policy, if you like, but in essence it seems to me quite democratic, for it involves a negligible sacrifice on the part of the individual for his own and the common good.

Summary

A survey is made of the position with regard to control of the five infectious diseases by preventive inoculation.

The various diphtheria antigens are reviewed, together with the methods of administration appropriate to each.

The necessity for more intensive propaganda in favour of immunization against diphtheria is urged.

The subject of active immunization against whooping-cough is discussed, and studies of recent crusades abroad are given.

Prophylactic immunization against measles, scarlet fever, and influenza is briefly dealt with.

OPHTHALMIC SERVICES TO THE CIVIL POPULATION IN NATIONAL EMERGENCY*

BY

Colonel A. IRVINE-FORTESCUE, D.S.O., M.B.
Special Certificate Civilian Anti-gas School, Easingwold

The subject of ophthalmic service in national emergency is a very wide one, and I propose to restrict my paper to an attempt to describe the conditions under which ophthalmologists will have to work in such an emergency. We have all heard many lectures and read numerous articles on conditions in Britain during the next war. Much that has been spoken and written on the difficulties we shall have to face in the event of hostilities strikes one as academic and unreal because of the lack of concrete examples and of descriptions of actual events.

The civil war which broke out in Spain in July, 1936, has afforded most interesting and instructive lessons in the effects of air raids on large cities. Since over 80 per cent. of the population of Britain is urban and approximately one-fifth of our people inhabit Greater London, it is obvious that the problem of defence against enemy attack from the air is a matter which chiefly concerns the town dweller. The city of Barcelona, with a population approximately equal to that of Glasgow, was frequently bombed from the air during 1937 and 1938. The most intensive bombing was on March 16, 17, and 18 last year. During these three days there were thirteen air raids. According to figures obtained from the local authorities by Mr. Langdon-Davies and published in his book *Air Raid*, the resulting casualties were 3,000 killed, 5,000 hospital cases, and 20,000 minor injuries. Statistics obtained by Major N. D. MacRoberts and published in his *A.R.P. Lessons from Barcelona* show that forty-eight large buildings were totally destroyed and 100 buildings, including sixteen theatres and cinemas, were partially ruined. Many streets were completely blocked with debris and remained impassable for days.

---

* Read in opening a discussion in the Section of Ophthalmology at the Annual Meeting of the British Medical Association, Aberdeen, July, 1939.

What an Air Raid Means

A good way of grasping what an air raid actually means is to read the official diary of a typical raid recorded at the time by A.R.P. headquarters at Barcelona and reproduced by Mr. Langdon-Davies. The diary runs as follows:

March 17, 1.58 p.m.—Orders received to sound air raid alarm signal.

1.59 p.m.—Presence of five enemy planes reported.

2 p.m.—Calls for ambulances received from eight different points.

2.31 p.m.—Delayed reports received from three further points.

3.50 p.m.—A serious fire is reported.

7.30 p.m.—Casualties in last raid reported as follows: one hospital, 80 dead and 229 wounded; another hospital, 335 dead and 350 wounded. Total, 415 dead and 579 wounded. A large number of casualties were still being dug out of the ruins.

This diary shows that a raid may take place without warning and that many hundreds of casualties may occur in a few moments.

It has not been possible to obtain statistics showing the proportion of eye injuries to total casualties in the air raids on Barcelona, but as a working estimate we may take 5 per cent. total wounded as having eye injuries of some sort. This would give thirty eye casualties admitted to hospital for the above raid and over 1,000 eye cases for the three days of fairly intensive bombing. Authorities appear to be convinced that in the next war the large towns of Britain will be much more intensively bombed than ever Barcelona was. We may therefore expect many more casualties per raid—three to four times the Barcelona figures, say 100 to 150 eye cases in a single raid without gas.

German bombing aircraft can carry over 4,000 lb. of bombs and have a radius of over 1,000 miles, so that no town in Britain can reckon itself safe. It is usual for bombs to be dropped in salvos from groups of aircraft. In the Barcelona case above referred to the group of machines numbered five, but this number may be largely increased.

The Effects of Aircraft Bombs

Aircraft bombs are of three kinds: (1) high explosive, (2) incendiary, (3) gas. In Spain high explosive bombs were the most frequently used and caused by far the greater part of the damage.

HIGH-EXPLOSIVE BOMBS

High-explosive bombs act by fragmentation, blast, and penetration. Pieces of the shell may cause wounds, the violent disturbance of the air set up by the explosive destroys buildings, and casualties are caused by falling masonry and material; or the bomb may penetrate a building and burst in the interior, producing a maximum destructive effect. When a high-explosive bomb bursts in a street there is first a pushing inward of all windows and doors opening on the street in which the bomb fell, and, secondly, a suction action which pulls the fronts of entire blocks into the roadway. These effects are produced up to a radius of 100 to 200 yards from the site of the explosion. It is easy to imagine how large numbers of casualties may occur from the collapse of buildings in this way.

INCENDIARY BOMBS

These bombs are much smaller than high-explosive bombs. The most effective weight appears to be about 2 lb., and thus very great numbers can be carried—1,000 to 2,000 by a single bomber. Experience in Spain shows that a large proportion of incendiary bombs dropped fail to produce fires, but supposing that only one in five was effective, the cargo of one bomber might produce 200 to 400 fires, and for a formation of fifteen to twenty planes these figures would be proportionally increased. We may therefore expect more fires than can be dealt with by the fire service and large numbers of casualties due to burns.

GAS BOMBS AND GAS SPRAY

A discussion of the use and effect of gas bombs is somewhat academic, as such bombs have not been used in Spain and China. But phosgene and mustard can be enclosed in bombs, and mustard can be distributed in the form of spray from the undercarriage of a plane. Also we know that during the great war gas was responsible for 180,000 casualties and 6,000 deaths among the British troops. It is believed that large quantities of phosgene and mustard bombs are being manufactured by certain powers. Aerial attack by gas bombs is therefore a possibility for which we must be prepared.

The gas which chiefly concerns the ophthalmologist is mustard, on account of the serious eye lesions produced by this substance. The lacrimator gases are unimportant from an ophthalmic point of view as their effects pass off in a few hours after the removal of the victim from the gas-charged atmosphere, without special treatment. Mustard, however, is extremely important. The crater of a mustard bomb gives off toxic vapour for days and even weeks; the action of the gas on the body is insidious, no symptoms usually being observed for two or more hours after exposure, and the resulting eye conditions are serious. Aerial bombs are peculiarly suited for the distribution of mustard. More than half the total weight of the bomb is accounted for by the gas content. A 50-lb. bomb will hold 17½ pints of liquid mustard. Further, a gas bomb has little tendency to bury itself, and most of its contents are spread over the ground. The most effective size of mustard bomb is either 50 lb. or 100 lb., and one bomber can carry sixty or more 50-lb. and thirty or more 100-lb. bombs. A 50-lb. bomb will contaminate an area of 360 square yards sufficiently to make a casualty of any unprotected person who enters this area for some days after the burst.

Continental authorities advocate aerial bomb attacks in successive waves of different kinds of bombs: first wave, high explosive; second wave, incendiary; third wave, mustard. The high-explosive bombs will destroy buildings and burst gas and water mains. The incendiary bombs will set fire to the ruins, aided by escaping gas and lack of water. The mustard will hamper the movements of first-aid and demolition parties.

Spray Attacks.—Mustard can be distributed in fine droplets projected from containers suspended from the undercarriage of a bombing plane. Mustard spray may be released from planes at a height so great that these are neither seen nor heard, so that the gas attack may come as a complete surprise, exposed persons having no time to put on their respirators before the mustard spray reaches them.

From the foregoing summary of the nature of aerial bomb attacks it is obvious that we should be prepared for large numbers of eye casualties occurring suddenly and with little or no warning. These casualties will fall into three classes: (1) effects of high explosives, such as concussion injuries and wounds, with or without a foreign body in the globe; (2) effects of incendiary bombs—namely, burns; (3) effects of mustard gas such as conjunctivitis and corneal ulceration.

Organization of Casualty Services

To provide for the numerous casualties that may be expected in the event of air raids local authorities throughout the country are arranging a system of collection, evacuation, and accommodation which will ensure that every victim of enemy action receives appropriate treatment at the earliest possible moment. When casualties are reported by the air raid warden service, first-aid parties of stretcher-bearers with ambulance cars will proceed to the spot indicated and guide or convey casualties to a "first-aid" post, where first-aid treatment will be rendered (and emergency operations performed). From the first-aid post light cases will be sent home, while cases requiring hospital treatment will be conveyed by ambulance car to a casualty clearing hospital, where urgent operative procedures will be carried out and cases re-classified into those requiring prolonged hospital treatment and those likely to be discharged in twenty-four or forty-eight hours. Cases needing prolonged hospital treatment will be evacuated by ambulance car to base hospitals situated in comparatively safe areas. Cases likely to be fit for discharge in a day or two may be retained in the clearing hospital if circumstances permit.

To supplement the organization of fixed first-aid posts there will be in every large town, and also in certain rural areas, mobile first-aid units. A mobile first-aid unit is to consist of a medical officer, a trained nurse, and eighteen women nursing auxiliaries, the latter arranged in three shifts of six each. A scale of drugs, dressings, splints, surgical instruments and utensils, and heating and lighting equipment sufficient for 250 casualties has been drawn up by the Home Office. The articles are packed in a series of portable cupboards, made up on the expanding bookcase plan. The medical officer, the trained nurse, and the equipment are to be carried in a large motor vehicle, and the auxiliary nursing personnel in a second vehicle. It is intended that the mobile unit should be stationed at a hospital, provided that this is not in a congested area. Where it is not practicable to have the unit at a hospital it will be located at a convenient centre on the outskirts of a vulnerable area. When an air raid occurs the mobile unit will proceed to the principal casualty area and open in any convenient building or in the open air. It is not proposed that first aid should be rendered inside vehicles. Mobile units of this type have been found most useful in Barcelona and Madrid.

It would appear that the provision of mobile first-aid units is a matter of vital importance and one which should receive the active support of all members of the British Medical Association. The provision of suitable vehicles with the necessary cupboards will involve considerable capital expenditure, which local authorities will often be reluctant to incur. Judging by the casualty figures in Barcelona, the allowance of dressings, drugs, and utensils for only 250 initial casualties per unit would appear to be hardly adequate. In the published list of equipment only two eye baths and one two-pint irrigator are allowed per mobile unit and also per fixed first-aid post.

I have tried to show why we may expect large numbers of eye casualties to occur suddenly, and I outlined the general medical arrangements by which it is proposed to deal with these casualties. I suggest that, to ensure uniformity of procedure and to maintain a high average standard in dealing with eye cases throughout the 200 or so local authorities in Britain, each of whom has its own scheme of casualty service, a system of consulting ophthalmic surgeons and ophthalmic centres should be organized on the lines adopted by the Army Medical Department in the great war. Under this system there was a Consulting Ophthalmic Surgeon to the Forces, who exercised a general supervision and direction over all ophthalmic work. Next there were Army and Command Consultants, who supervised work in limited areas. Finally in each army over-seas and at each command at home there were one or more ophthalmic centres attached to general and base hospitals in which eye casualties were collected and treated. I submit that only by some such centralized supervision and regulation in a period of air attacks on Britain can the best results be ensured for eye casualties among the civil population.

Conclusion

Let me here add a few words about a personal experience of a mustard gas attack and of the deductions to be drawn therefrom. On July 22, 1917, I was in command of a field ambulance stationed on the Belgian coast near La Panne. Within twenty-four hours I had to admit nearly 2,000 mustard gas casualties. The great majority of these were completely blind. Although roughly 80 per cent. were fit for duty again in a fortnight, all were hospital cases for the time being. It was essential to treat as many cases as possible simultaneously, and to expand my bed accommodation rapidly. As the result of my experience I would strongly urge upon all Association members interested in eye work that they should agitate for the provision in their respective areas of the following: (1) A supply of marquees sufficient to allow of existing hospital accommodation being rapidly increased. (2) A supply of auxiliary nursing personnel specially trained in eye irrigation. (3) A sufficient supply of irrigators to allow of a considerable number of mustard eye casualties being treated simultaneously.

Summary

This paper is an attempt to describe the conditions under which ophthalmologists will have to work on the home front in war time.

The number of eye casualties we would have to expect, based on the example of the civil war in Spain, is discussed.

The results of the use of the various kinds of aerial bomb, and particularly of mustard gas bombs and mustard gas spray, are reviewed.

A suggestion is made as to the general arrangements by which to deal with eye casualties.

Glucose Tolerance and Acid-base Equilibrium.—The literature relating to disturbances of carbohydrate metabolism found in patients suffering from some mental disorders and to disturbances of the acid-base equilibrium, also stated to be present in some psychotics, is reviewed. Experiments are reported which were designed to show the presence or absence of correlation between the two disturbances. Results of the investigation were negative, no such correlation being found. It is therefore concluded that changes in acid-base equilibrium are not responsible for the alterations in carbohydrate tolerance.—Disturbances of Glucose Tolerance and of Acid-base Equilibrium in Manic-depressive Insanity. TRANSFUSION WITH STORED BLOOD

BY

J. C. LEEDHAM-GREEN, F.R.C.S.

Honorary Assistant Surgeon, North Staffordshire Royal Infirmary; late Resident Surgical Officer, General Hospital, Birmingham.

Although reports of the value of stored blood for transfusion purposes have been published recently by Biddle and Langley (1939), Elliott, Macfarlane, and Vaughan (1939), Vaughan (1939), and other writers, its widespread adoption has not yet followed. The advantages of a ready supply of stored blood are manifest and have been sufficiently emphasized by the authors I have named. From my own experience during the last twelve months I can echo their enthusiastic reports. There is, moreover, one advantage of stored over fresh blood to which, so far as I am aware, no reference has been made, and that is the diminished risk of transmitting syphilis. According to Neisser (1914) the *Treponema pallidum* loses its virulence after twenty hours in an ice-chest.

Collecting and Storing the Blood

Complicated and expensive apparatus is not needed for collecting or storing the blood. The one essential is that the blood should be withdrawn with every aseptic precaution into a *closed* bottle, and the purpose of this communication is to give my experience with sixty transfusions of stored blood at the General Hospital, Birmingham, using the method of collecting blood described by Marriott and Kekwick (1935). The donors were all members of the Birmingham Blood Transfusion Service, and were either Group II or Group IV (Moss). There is no need to enlarge on Marriott and Kekwick's method of bleeding donors, for they have described it fully. The blood is collected in a graduated quart milk bottle in which a negative pressure is maintained by means of a Dunlop foot-pump in which the valve has been reversed. If such a pump is not available a Potain's aspirator will serve the purpose. The average amount of blood collected from each donor was 600 c.cm., and this was mixed with 100 c.cm. of 3.8 per cent. sodium citrate solution.

After the blood had been collected the bottle was sealed with a plug of sterile cotton-wool round which a layer of gauze had been wrapped to prevent the wool from sticking to the neck of the bottle. A test tube with a few drops of the donor's blood in citrate solution for the cross-agglutination test between the donor's corpuscles and the recipient's serum was attached to the bottle with a rubber band. Finally the bottle was labelled with the date on which the blood had been taken and the group, and immediately conveyed to a refrigerator which maintained a temperature of about 4° C.

The Present Series

Fifty-three donors were bled and sixty transfusions given. In several cases two transfusions were given from blood collected from one donor. One bottle was discarded on account of excessive haemolysis. The average length of time the blood was kept before it was used was 5.5 days. The longest period was twenty-eight days, and no reaction followed the transfusion of this blood. The average length of time the blood had been kept in those cases showing reactions was four days. The blood was given by the gravity method, and in one case by means of Marriott and Kekwick's drip-transfusion apparatus.

Reactions

Reactions were observed in twelve cases, as follows: severe rigors, one case; slight rigor or shivering attack, eight cases; pyrexia, three cases. There were no instances of jaundice or haemoglobinuria. The reactions were equally divided among the patients of Group II and Group IV. In four of these cases it is not improbable that other factors besides the blood were responsible.

Case 1.—A patient with microcytic anaemia developed a slight rigor eleven hours after the transfusion.

Case 2.—A man who had been transfused after a perineo-abdominal excision of the rectum developed a rigor, but at the time of the rigor was actually on an intravenous glucose "drip."

Case 3.—A man with a bleeding peptic ulcer showed a rise in temperature to 101° twelve hours after transfusion.

Case 4.—A boy of 15 with leukaemia developed a temperature of 101.4° after transfusion.

In the last case the blood had been transfused a few hours after it had been taken. Blood from the same bottle was given three days later to another patient without any reaction developing. In the last two of these cases it is just as likely that the rise of temperature was a natural feature of the disease as that it was an effect of the transfusion. If these two be excluded from the twelve cases which showed a reaction we are left with ten, giving a reaction rate of 16.6 per cent. This rate is almost identical with that found by Vaughan (1939) in fifty consecutive transfusions with stored blood at the British Postgraduate Medical School. Although I have no figures for comparison I have an impression that this reaction rate is no higher than after the transfusion of fresh blood, and the various ward sisters are of the same opinion.

Haemolysis which is apparent to the naked eye usually starts after the blood has been stored from ten to fourteen days, but may appear much earlier if there has been difficulty in securing a rapid even flow from the donor, if clot is present, or if the blood has been taken out of the refrigerator and allowed to get warm in anticipation of a transfusion and then returned to the refrigerator. Blood in which the supernatant plasma has turned red should be discarded, and, as stated, one bottle was discarded for this reason; but a slight degree of haemolysis does not appear to give rise to any unpleasant sequelae. Routine bacteriological tests were not carried out, but occasional samples were cultured and were always found free from microbic contamination.

It is my pleasure to express thanks to the medical and surgical staffs of the General Hospital, Birmingham, for free access to their cases, and to Dr. W. T. Hillier for the bacteriological examinations and much friendly advice. I owe a special debt of gratitude to numerous donors and to Mr. H. E. Cooper, the honorary secretary of the Birmingham Transfusion Service. His friendly co-operation made this work possible.

CHOICE AND PREPARATION OF BLOOD-GROUPING SERA FOR EMERGENCY PURPOSES

BY

S. W. CHALLINOR, Ph.D., B.Sc., A.I.C.

J. C. J. IVES, M.B., Ch.B.

AND

C. E. van ROOYEN, M.D.

(From the Department of Bacteriology, University of Edinburgh)

During the past few weeks we have been confronted with the problem of supplying relatively large quantities of human typing sera at a few hours' notice, and the purpose of this paper is to record the methods we employed, in the hope that they may be of help to others faced with the same situation.

The selection of the typed volunteers constituted our first problem, and this was accomplished with the aid of a small quantity of blood-grouping sera* of Group II (Moss)—that is, international classification A; and Group III (Moss)—that is, international classification B. With these a number of human volunteers were duly typed. (For the remainder of this paper we have adopted the Moss classification.) From these individuals four of Group II and four of Group III were chosen for tests, the object of the experiments being to find out which of them could provide the most active sera for standard typing purposes. In order to obtain this information it was decided to set up a series of increasing dilutions of each individual's serum, to which was added a suspension of red blood cells. In this way it was possible, first, to determine which of the sera produced clumping in the highest dilution, and, secondly, to ascertain the character and nature of the clumping produced. The results of our experiments showed that the serum possessing the highest end-titre of agglutinins was not necessarily the serum of choice for typing purposes, since we observed that the qualitative character of the reaction—for example, the size and appearance of the clumps as seen by the naked eye—was a better criterion of the value of sera for typing work than the end-titre at which the reaction occurred. We wish to point out that some sera give agglutination reactions that are easily visible to the naked eye, whereas with others such reactions are not so marked and the time taken for agglutination is longer. It is desirable to add a preservative to typing serum, and of the two most suitable reagents, phenol and glycerol, we decided to use phenol in order to avoid excessive dilution of the serum. For a comprehensive account of human blood groups the reader is referred to the monograph of Dawood Matta (1937). Details of the experimental methods employed by us are as follows.

Collection of Blood

Ten c.cm. of blood was removed from each of four Group II donors, was allowed to clot overnight in the ice-chest, and was separated from the sides of the test tube with a platinum wire and centrifuged; the serum was then separated. From one of this same group a further 10 c.cm. of blood was withdrawn, added to 10 c.cm. of 3.2 per cent. sodium citrate solution, centrifuged, the deposited corpuscles washed thrice in physiological saline, and 100 c.cm. of a 1 per cent. suspension in saline of these cells prepared. There was now available (1) about 3 c.cm. of serum from four different Group II donors, and (2) 100 c.cm. of a 1 per cent. saline suspension of washed Group II corpuscles. Exactly the same procedure was adopted with regard to the four Group III donors, so that four specimens of Group III serum—that is, containing agglutinin α—were available, together with one specimen of Group III corpuscles—that is, containing agglutinogen B.

Technique of Titration Test

For the testing of each serum eleven Wassermann tubes were placed in a rack and 0.4 c.cm. of saline was added to tubes Nos. 2 to 11 inclusive. To the first and second tubes 0.4 c.cm. of serum (from the first donor to be tested) was added. From tube No. 2, 0.4 c.cm. of the diluted serum was transferred to tube No. 3, and from this tube the process was repeated until tube No. 10 was reached, from which 0.4 c.cm. was discarded. The serum dilutions of No. 1 donor were thus as follows: 0.4 c.cm. of undiluted serum in the first tube, 0.4 c.cm. of 1:2 serum in tube No. 2, 1:4 in No. 3, and so on with the highest dilution of 1:512 in tube No. 10. Tube No. 11 contained only 0.4 c.cm. of saline and constituted the control. Red blood corpuscles of Group III were next added (0.4 c.cm. of a 1 per cent. suspension in saline to each tube), so that each dilution of serum became doubled, and thus tube No. 1 contained a final dilution of serum diluted 1:2, and tube No. 10 a dilution of 1:1024. The control tube now consisted of a mixture of normal saline and red blood cells. The test tubes were then incubated at 37° C. for one hour; at the end of that time a preliminary examination of the tubes was made with the aid of a hand lens, following which the tubes were allowed to stand overnight on the

Final Serum Dilution (against Group III Corpuscles)

* Burroughs Wellcome and Co., London.

laboratory bench at room temperature, being subjected to a final reading in the morning (after eighteen hours).

This method of testing serum (No. 1) for haemagglutinating properties was repeated in the case of the other three sera (of Group II). In actual practice it was our procedure to set up all the serum dilutions simultaneously, add corpuscles of Group III to the four Group II sera and corpuscles of Group II to the four Group III sera, incubate the test tubes together, and interpret all the results, first at the completion of one hour and later at the end of eighteen hours. The table indicates the results obtained.

From the foregoing table the following definite fact can be observed—namely, that each of the diluted sera tested gave approximately the same end-agglutination titre (approximately 1:128 for serum of Group III Moss). We wish to point out that human sera possess different agglutinin end-titres, but in the present work the ones used happened to have approximately equal end-titres; also, in each group variations are found in the degree of agglutination given by different corpuscles with the same serum. It was seen, too, that each of the four sera showed a dilution at which optimum agglutination occurred. As already stated, in addition to these quantitative observations there were definite qualitative differences in the nature and size of the clumping which enabled us to select certain of these sera as being the most suitable for the purpose of blood grouping.

Storage of Serum

Having chosen the two most suitable donors from each of Groups II and III, half to three-quarters of a pint of blood was withdrawn from each donor into sterile pint bottles and allowed to stand overnight in the ice-chest. During this preliminary storage the absorption of any "cold" agglutinins takes place. The separated serum was transferred by means of sterile pipettes into sterile 100 c.cm. bottles. In order to maintain sterility phenol (5 per cent. aqueous solution) was then added to the serum so that the phenol concentration was 0.5 per cent. For distribution purposes the phenolized serum was transferred in 1 c.cm. quantities to sterile phials fitted with rubber bungs, which were afterwards waxed.

Use of Desiccated Serum

An alternative method for the preservation of typing sera which we used was that employed earlier by Craigie (1931) and Craigie and Tulloch (1931) for the preservation of sera by exsiccation *in vacuo* from the frozen state. Using this method, it is possible to dry rapidly in a desiccator over $CaCl_2$ large quantities of serum. The final product, which assumes the character of a dry brown flaky powder, can be stored in the ice-chest for an indefinite length of time without fear of contamination or significant loss of agglutinating properties. On account of its hygroscopic nature the container should be sealed or well stoppered. The only disadvantage of the use of dried serum is that larger quantities are required than of the fluid serum; but this disadvantage is offset by the fact that desiccated serum is easily distributed and handled, and, in any case, the actual amount of dried serum needed for a typing test is exceedingly small.

When it is desired to make a quantity of serum from dried material it is necessary to reconstitute the dried serum to the original bulk by the addition of sterile distilled water; thus if 5 c.cm. of serum were desiccated to a dry powder, 5 c.cm. of water should be added to it in order to restore its original consistency.

Technique of Typing Test

For typing human serum we have employed the standard macroscopic procedure of the London Blood Transfusion Service. Briefly, this was performed by placing two large drops of typing sera of Groups II and III respectively on a glass plate, to each of which was added *one small* drop of blood obtained from a finger-prick, care being taken to see that only enough blood was added to colour the mixture light pink, but not deep red. After thoroughly mixing the blood and serum by agitating the plate, the results were usually evident in one to two minutes. The use of a hand lens was occasionally of assistance in interpreting the phenomena, but, in general, neither a hand lens nor a microscope was required.

Technique of Test employing Dried Serum

A few small flakes (one bacteriological loopful) of dried serum of each of Groups II and III were placed on a glass plate; a large drop of water was added to each and the serum allowed to dissolve by gentle mixing. The subsequent stages of the test were performed in the same manner as in the case of fluid serum.

Conclusions and Summary

From our observations we conclude that the selection of suitable blood intended for the purpose of providing standard human blood-grouping sera should be assessed in two ways: (1) according to the end-titre of agglutinins; (2) by considering also the character and size of the clumps produced after a given length of time.

The use of desiccated typing sera is described and its merits for war-time work emphasized.

We wish to record our thanks to the Edinburgh Blood Transfusion Emergency Service for help in withdrawing the blood from the donors selected by us, and to Professor C. H. Browning for his interest and valuable advice.

A quarterly court of the directors of the Society for Relief of Widows and Orphans of Medical Men was held on October 11, with Mr. V. Warren Low, president, in the chair. The deaths of a member and two of the widows in receipt of grants were reported. One of the widows had been in receipt of grants for the past thirty-four years and had received £3,500 from the society. Her husband, who was elected a member in 1868, had paid £52 10s. in subscriptions. The audited accounts for the half-year ended June 30 were presented and passed. During that period £2,242 10s. had been distributed among the sixty-two widows and four orphans on the books of the society. A widow of a member applied for relief, and was granted £60 yearly. The grants in January, 1940, will total £2,152. Owing to the increase in income tax the directors will not be able to make a Christmas present this year although the amount of income tax is returned, as the reclaim is not paid until about the middle of April in each year. Membership of the society is open to any registered medical man who at the time of his election is resident within a twenty-mile radius of Charing Cross. Relief is granted only to widows and orphans of deceased members, and they must be in necessitous circumstances. Full particulars may be obtained from the secretary of the society, 11, Chandos Street, Cavendish Square, W.1.

SEVERE UTERINE INERTIA TREATED BY CUTTING THE CERVIX

BY

J. V. O'SULLIVAN, M.D., F.R.C.S., M.R.C.P.

Assistant Obstetric Surgeon, City of London Maternity Hospital and Queen Mary's Hospital, Stratford; Consulting Obstetrician and Gynaecologist, Kingston and District Hospital; Obstetric Surgeon, Bearsted Memorial Hospital

Severe uterine inertia is one of the most difficult problems of midwifery. I think inertia should be divided into primary and secondary types; primary where no cause for the inertia can be found, and secondary where a definite cause—for example, disproportion or rigid cervix—is present. Most doctors are acquainted with the course of a severe case of inertia. The labour often starts with early rupture of the membranes. Uterine contractions remain weak and irregular for two or three days, during which time the liquor drains away. The cervix is slowly taken up, but does not dilate to more than two to three fingers. The head is by now deeply engaged in the cavity, and the cervix, which looks normal and caps the head, can often be seen by parting the labia and looking into the vagina. The uterus still relaxes well between pains, and the mother and foetus are still fit; but about this stage the patient has a tendency to bear down with pains. From now on she often complains of pain in the sacral region and sometimes behind the pubis, due probably to pulling on the utero-sacral and pubo-cervical ligaments as the cervix descends in front of the head. The patient, in short, seems to be trying to pass her uterus. Next a caput begins to form through the os, and soon meconium appears. During the following twenty-four hours or so the uterus relaxes less well and becomes tender to palpation; the foetal distress increases, while maternal distress, as seen by vomiting, rising pulse rate, and temperature, appears. The liquor becomes foul-smelling, and about this time the foetus usually dies *in utero*. The soft macerated head gradually bulges through the undilated cervix, forcing it open, and eventually by help of the obstetrician a macerated foetus is delivered. Perforation is usually necessary, and great difficulty is experienced in crowning the head and delivering the body because of the active retention of the foetus by the uterus (Holland). A morbid puerperium, with sloughing of the perineum, is the rule.

I was led to try the effect of cutting the cervix laterally for these unhappy patients by observing cases in which the cervix was buttonholed through either the anterior or posterior lip, and particularly two cases in which the cervix completely sloughed off and came away on the foetal head during the delay in labour. The site of the incision was largely determined by the fact that in many normal deliveries the cervix, as is well known, tears laterally. I first treated severe inertia cases, which had resisted medical treatment, by slow continuous or repeated manual dilatation of the cervix, by weight traction through Willett's scalp forceps, or, if the foetus was dead, by perforation followed by weight traction. I have also cut the cervix in front and behind, and immediately delivered the foetus by forceps if alive, and by perforation if dead, and then sutured the cervix. I was not satisfied with any of these procedures, so ultimately adopted the method which I propose to describe in this article.

Technique

The operation is simple, and can be done in a few minutes under any light anaesthesia, or even with Minnitt's gas-and-air analgesia machine. Two fingers are inserted into the cervix, one outside and one inside, to guard the side wall of the vagina and the foetal head respectively, and the cervix snipped with blunt-pointed scissors, usually at the lateral angles (roughly corresponding in position to 9 and 3 of the clock dial), which are already thinner than the rest of the cervix and often beginning to tear spontaneously. If the operator wishes a Sims duck-bill speculum can be passed and the cutting done under direct vision. The incision should not extend more than half an inch from the edge of the cervix, and should be preceded and followed by a hot antiseptic douche. Two incisions only should be made, one at each side. The cervix, after cutting, should be pushed gently up over the front of the head. The opportunity should be taken of stretching the vagina and ironing out the perineum. The patient is now allowed to come out of the anaesthetic.

Before this operation is attempted the usual methods of treating such cases should have been tried—for example, sedatives, hormone therapy (Jeffcoate), and a full medical induction. The head should be deeply engaged, the cervix taken up, thin, and capping the foetal head, and the membranes ruptured. If these points are observed the loss of blood is negligible—only a few drachms. The cervix should not be cut if it is oedematous or thick. I do not suture the cervix after delivery because with the small incision it is not needed and further tearing is slight. Patients in whom contractions are regular but half-hourly and advance is very slow, and in whom low sacral ache and retropubic pains develop, are immediately relieved of these pains, and labour ends rapidly and spontaneously. Where contractions are very irregular and weak labour is slower in ending, and sometimes a low forceps operation is necessary in the second stage.

There is another point I should like to stress particularly, and that is that morphine should never be given as routine to these patients; potassium bromide and chloral, 40 grains of each orally or rectally, or paraldehyde, 8 drachms rectally, act excellently. These drugs should be given alternately, preferably at night. The patient should also be encouraged to sit up as much as possible by day and should be given plenty of fluids and carbohydrates. When vomiting is troublesome a rectal or intravenous glucose saline should be administered.

Results

Patients needing this operation are rare, so I have been able to collect only fourteen cases in three years, one in private and twelve in hospital practice, out of about 9,000 to 10,000 deliveries which came under my supervision. It will be seen, however, from the analysis that in suitable cases the operation is highly successful. The cervices, when examined either during the puerperium or at post-natal visits, showed a transverse laceration, no worse in five cases than the cervix after many normal labours. In the others the transverse slit was well marked, but in no case did it involve the whole portio vaginalis. One of these women has had two normal labours and one miscarriage at four months since the operation.

I have included in this series one case in which marked foetal distress, as shown by meconium in large quantities and a foetal heart rate of 90 to 100 between pains, developed when the os was three fingers dilated. The pains were strong and regular. I cut the cervix as described, stretched the vagina, and ironed out the perineum under light anaesthesia. The baby was born, alive and well, one hour later.

Case 1.—Emergency. Aged 18; primipara. No disproportion. No toxaemia. Spontaneous onset; membranes ruptured seven hours after. Pains weak but regular. Sedatives given. Os still only three fingers after sixty-one hours. Cervix cut as described. 7½-lb. baby born spontaneously 2 hours 20 minutes later. Excellent result. Mother and baby satisfactory. Cervix healed.

Case 2.—Booked case. Aged 24; primipara. Full term. No disproportion. No toxaemia. Spontaneous onset; membranes ? ruptured on admission. Pains regular. Much pain in lower sacrum. Sedatives given. After seventy-one hours os three fingers only; cervix taken up; liquor scanty. Cervix cut. 7¼-lb. baby born spontaneously three hours later. Excellent result. Mother and baby satisfactory.

Case 3.—Booked case. Aged 31; primipara. Full term. No disproportion. Mild toxaemia. Medical induction, as no pain and membranes ruptured. Pains irregular and weak. After fifty-two hours os three fingers only; liquor became scanty, green, and offensive. Sedatives and stilboestrol tablets given with no effect. Cervix incised under gas and air. Baby born spontaneously, in blue asphyxia, fifteen hours later. Good result. Cervix healed at end of puerperium. Mother and baby did well.

Case 4.—Booked. Aged 30; primipara. Full term. No disproportion. Oedema of legs only. Spontaneous onset, membranes ruptured before labour started. Pains week. early maternal distress. Sedatives and medical induction given. After forty-eight hours os still only two fingers. Cervix cut. Baby born twenty-two hours later; head lifted over perineum after two hours in second stage. Baby 8½ lb. Good result. Mother and baby satisfactory.

Case 5.—Emergency. Aged 21; primipara. Full term. No disproportion. No toxaemia. Spontaneous onset, membranes ruptured after sixty hours. Pains regular. Sedatives, stilboestrol, prontosil, glucose, etc., given. After 130 hours os still three fingers; much meconium. Cervix incised under gas and air. 10¼-lb. baby born seven hours later. Delivered by forceps because of maternal and foetal distress. Very good case. At post-natal examination condition satisfactory; cervix showed slits no worse than many normal labours.

Case 6.—Booked, private. Aged 21; primipara. Full term. No disproportion. No toxaemia. Spontaneous onset; membranes ruptured twenty-four hours later. Pains regular; much pain in lower sacrum. Sedatives given. After seventy-two hours os still three fingers; much meconium. Cervix incised under gas and air. 7¾-lb. baby born spontaneously three hours later. Cervix stitched at end of third stage. Excellent result. Two normal labours and one miscarriage since—no inertia.

Case 7.—Booked. Aged 31; primipara. Full term. No disproportion. No toxaemia. Medical induction. Pains regular but weak. Severe pain in lower back. After forty-five hours os still two fingers. Cervix cut under chloroform. Baby, 8 lb. 2 oz., born eleven hours later. Easy low forceps delivery. Later manual removal of placenta because of P.P.H. Good result. Both satisfactory.

Case 8.—Aged 25; primipara. Full term. No disproportion. No toxaemia. Spontaneous onset; membranes ruptured. Contractions poor to fairly strong. Much pain in lower sacrum and pubis. Maternal distress after thirty-six hours. After fifty-one hours os still three fingers. Cervix cut under light chloroform. Baby, 8 lb. 6 oz., born five hours later, spontaneously. Excellent result.

Case 9.—Booked. Aged 27; primipara. Full term. No disproportion. No toxaemia. Spontaneous onset. Pains irregular at first, and weak. Membranes ruptured on admission. Much pain in lower back. Sedatives and oestradiol given; no effect. After seven days os still only three fingers; maternal and foetal distress present. Cervix cut under gas and ether. Baby, 8 lb. 14 oz., born spontaneously eight and three-quarter hours later. Excellent result. Mother and baby satisfactory.

Case 10.—Emergency. Aged 29; primipara. Full term. No disproportion. No toxaemia. Spontaneous onset seventy-two hours before admission. Membranes ruptured by doctor. Foetal heart not heard. Contractions irregular and weak. Much pain in sacrum and pubis. After eighty-nine hours os still three fingers; maternal distress; meconium and little liquor. Cervix cut under whiff of A.C.E., and baby, stillborn and weighing 6 lb. 8 oz., delivered by forceps three and a half hours later. Good result. Mother's condition satisfactory at post-natal visit.

Case 11.—Emergency. Aged 23; one miscarriage. Full term. No disproportion. No toxaemia. Spontaneous onset; quinine after three days. Foetal movements stopped after six days; patient admitted. Pains moderated. Morphine given twice by outside doctor. On admission given glucose, anti-gas-gangrene serum, etc. After seven days os three fingers; maternal distress, offensive discharge of meconium and liquor; foetus dead. Cervix cut under gas and air, and stillborn baby, 8 lb., born spontaneously seven and a half hours later. Excellent result.

Case 12.—Booked. Aged 25; primipara. Full term. No disproportion. No toxaemia. Spontaneous onset. Pains slight; membranes ruptured early. Given sedatives and oestroform, with no effect. After 151 hours os two to three fingers only. Cervix cut. Baby born spontaneously twenty-three and a half hours later, weight 7 lb. 12 oz. Good result. Baby satisfactory. Mother—no milk, only serum in breasts.

Case 13.—Booked. Aged 24; primipara. Full term. First degree disproportion. No toxaemia. Spontaneous onset. Pains weak at first. Membranes ruptured four days after onset. Severe backache. On fourth day maternal distress marked; liquor became yellow and offensive. After 123½ hours mother's temperature 102°, pulse 120. Foetal heart not heard. Os two to three fingers dilated. Cervix cut. Os full six hours later and stillborn baby delivered by low forceps. Very good result as regards the operation. Mother developed septicaemia and peritonitis, and died twelve days after delivery. P.M.: no injury to uterus; general peritonitis present.

Case 14.—Booked. Aged 31; primipara. Twins. Aortic and mitral disease; toxaemia of pregnancy. At thirty-eighth week membranes ruptured spontaneously. Pains weak about one in ten. Patient was treated with sedatives, oestroform, etc. Os only two to three fingers dilated at end of ninety-eight hours. Maternal distress now well marked. Cervix cut at lateral angles without anaesthetic and without upsetting patient. Cervix immediately retracted. Six hours later os fully dilated. Easy forceps deliveries. Mother and babies did well. Post-natal examination showed a normal pelvis and multiparous cervix.

The following is not a case of inertia, but is interesting from the point of view of the marked shortening of labour after cutting of the cervix, with stretching of the vagina and ironing out of the perineum:

Booked case. Aged 20; primipara. Full term. No disproportion. Slight toxaemia. Admitted in labour. After sixteen hours os three fingers; pains strong and regular; scarcely any liquor left; marked foetal distress, foetal heart 80–90 between pains; much meconium. Os incised under gas and air, and baby born spontaneously one hour later. Mother and baby satisfactory.

Synopsis of Cases

All the patients were primigravidae, between the ages of 18 and 31. All the mothers made an uninterrupted recovery except one in whom the intranatal pyrexia continued into the puerperium, causing peritonitis and death. Four of the cases were emergencies, the rest booked. Nine babies were born spontaneously, alive and well. Four of the babies were stillborn, three macerated: two of these were emergency cases; in one, foetal distress was well marked on admission, while in the other the foetal heart could not be heard. Seven babies (one set of twins) were delivered by low forceps. Time in the first stage before operation: 45, 48, 51, 52, 61, 71, 72, 89, 98, 123½, 130, 151 hours, 7 days, 7 days. Average hours in labour before operation, 94. In no case was the os more than three fingers dilated. Average interval between operation and termination of labour, nine hours. Three patients were actually delivered spontaneously in three hours or less.

Conclusion

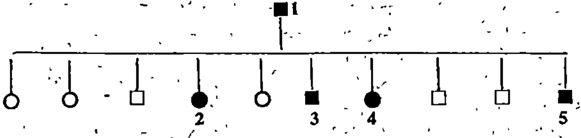
A simple method of expediting cases of severe uterine inertia has been described, and though the number is small, I feel confident that if cases are selected as described the treatment is simple and very successful.

Clinical Memoranda

Familial Ptosis with Ophthalmoplegia Externa starting in Adult Life

Ptosis occurring congenitally in members of the same family is fairly common, and occasionally this is combined with external ophthalmoplegia (Panas, 1896; Cooper, 1910). Frequently, also, a condition of congenital ptosis, ophthalmoplegia, and epicanthus has been described, and the condition has been recorded in detail in four generations by C. H. Usher (1925–6). Ptosis starting in adult life associated with external ophthalmoplegia of a slowly progressive type is comparatively rare. Beaumont (1900) reports twelve cases in three generations. In these cases the disease always had its onset in adult life.

In the family, to be described five cases occurred in two generations—the father and four children, two male and two female. In Case 4 the signs were present as a child; in the others not until about 30 years of age. Apart from one affected male who died from generalized tuberculosis aged 45, the family of the affected father were otherwise healthy, and eight of the ten children are still alive. Internal ophthalmoplegia was not noticed in any of the patients examined, and there was no history of goitre.



Case 1.—The father, who was an only child, died at 49, at which time he had severe ptosis of both upper lids, but especially of the left. He had to hold up his lids to see properly. I have seen a photograph taken some years before his death showing the ptosis.

Case 2.—Mrs. A., aged 65, has two daughters, aged 35 and 32, not affected so far. She has bilateral ptosis, which came on approximately at 30 to 35 years of age, and wears props attached to her spectacles to keep her eyes open. Her upper lids cover three-quarters of the pupillary area in the right and almost the total pupillary area in the left (4 mm. pupils). She has no diplopia, but there is limitation of the ocular movements, with only very slight movements of the eyes upwards, marked limitation laterally, and some diminution of downward movement.

Case 3.—Mr. B., died aged 45, had left-sided ptosis at the time of his death.

Case 4.—Mrs. C., aged 59, states that her lids have been drooped since a child, and blames an attack of measles for the onset of the trouble. Her left lid covered approximately five-sixths of the pupillary area, and the right covered the upper third. The pupils were approximately 3 mm., and no evidence of external ophthalmoplegia was found. She has defective upward movement and some lateral diminution of the movement, apparently more marked, of the left eye to the left side. There is no diplopia. She has no family.

Case 5.—Mr. D., aged 53, has had trouble since before 30 years of age. The lids cover half of the right and two-thirds of the left pupillary area (pupils approximately 5 mm.). He complains bitterly of diplopia, and to avoid this keeps the left eye closed. The diplopia is chiefly due to left hypotropia. There is no upward movement of the left eye, and diminution of lateral movements of the eyes. I have suggested trying prisms or even a tarsorrhaphy on the left side, but he prefers to continue as before. The patient's family have, I understand, no signs of similar trouble, but I believe the eldest is still under 30 years of age.

Traumatic Pancreatitis in a Child

The memorandum by Mr. Armstrong in the *Journal* of June 17 (p. 1230) prompts me to record the following case.

Case History

A boy aged 7 went home crying and told his mother of a kick in his stomach. It was not till after three days that severe abdominal pain set in. As a brother had died of acute appendicitis the parent summoned the doctor, who noted the spasmodic nature of the pain but at first found no tenderness. Later in the day he suspected peritonitis and sent the patient to hospital. The aspect of the child accorded well with acute appendicitis, and the right iliac fossa was very tender. However, on further examination the tenderness was found diffuse. It was in the hypogastrium, well marked in both loins and across the epigastrium; this led to misgivings about the diagnosis, and these deepened when heavy glycosuria and slight acetonuria were discovered. Traumatic pancreatitis suggested itself, but was dismissed because of the lucid interval since the alleged accident. Evidently peritonitis existed though the cause thereof was obscure.

On July 13, 1938, under spinal anaesthesia, a thickening was felt beneath the right rectus about the level of the transverse colon. Through a right paramedian incision bile-stained fluid ran forth, also some coagulated lymph. On depressing the transverse colon watery swelling and fat necrosis were noted in the gastro-colic omentum, which I opened to drain the damaged pancreas. A suprapubic drain was next inserted, and, finally, a retroperitoneal stab drain was used in the right iliac fossa to evacuate a bag of watery exudate behind the posterior iliac peritoneum. The patient recovered rapidly, and when seen two months later he was very well.

The interesting features in the case are: (1) The age of patient (7 years). (2) The latent period of three days before peritonitis; this was also noted in Armstrong's case. (3) Gravitation of retroperitoneal exudate from the pancreas into the right iliac fossa, which drew attention away from the underlying lesion.

Bristol. A. WILFRID ADAMS, M.S., F.R.C.S.

Catatonia.—This condition, persisting for twelve days, is described in a cannabis indica addict. During this period the patient was terrified by the mention of police or prison. The origin of this condition in cannabis indica addicts is discussed. The author considers that it is produced by cortical inhibitions produced by the drug, leading to the liberation of automatic subcortical mechanisms.—Catatonic Syndrome in Acute Psychosis due to Cannabis Indica. P. Scouras.—*Encéphale*, February, 1939, **34**, 78.

Reviews

EXPERIMENTAL MEDICINE

The Harvey Lectures, 1938–39. Delivered under the auspices of the Harvey Society of New York. Series 34. (Pp. 279; 16 illustrations. 18s.) London: Baillière, Tindall, and Cox. Baltimore: Williams and Wilkins Company. 1939.

We always look to the annual Harvey Lectures for enlightenment on some of the more obscure aspects of experimental medicine, and not in vain, although as time goes on they inevitably become more specialized in their interest.

Professor G. F. Marrian leads off with a discussion of the metabolism of those hormones which may be conveniently termed "steroids," since they all contain a particular phenanthrene ring; the group includes the natural occurring androgens, oestrogens, progesterone, and adrenal cortical hormone, in addition to many others synthetically prepared. Much work has been done on their biochemical history in the body, and, as the author remarks, speculation on their possible modes of origin and conversion is becoming the fashionable biochemical pastime. Dr. A. A. Weech deals with the behaviour of the albumin fraction of serum and its response to dietary changes in the hope of throwing light on the rational treatment of patients depleted of this constituent of the blood. Professor E. J. Cohn discusses at length the chemistry of proteins, with special reference to their ionic nature. Professor E. F. du Bois, after a full investigation of the factors controlling the loss of heat from the human body, pathetically expresses his doubt that any of this work will have the slightest influence on clothing, since here custom and fashion reign supreme. Dr. E. A. Park's detailed consideration of the pathology of rickets is full of interest. He does not believe that withdrawal of lime salts from the organic matrix occurs in rickets. Decalcification of bone is a misleading phrase, for the calcium salts are not simply dissolved out. Nature's method of obtaining the calcium is to break down the organic matrix at the same time as the mineral content is released. Osteoid—that is, bone free from lime salts—is a stage in normal growth, mineral deposit coming later. The presence of osteoid in excess is a cardinal sign of rickets, the well-known defective absorption of calcium from the bowel preventing its deposit. The characteristic irregularity of formation of osteoid in rickets follows exactly the lines which might be expected in view of the fact that pressure stimulates new formation of bone and tension exerts no influence at all, unless an actually destructive one.

Dr. Linderstrom-Lang's lecture on enzymes in tissues and cells is for the biochemical elect, but Professor Szent-Györgyi's contribution on biological oxidation and vitamins, though abstruse, contains some interesting generalizations with a clinical bearing. Although the radiant energy of the sun is the ultimate source of all life-sustaining energy it cannot as such directly support life; otherwise life would fail at night. It is known that chlorophyll is the intermediary, but it is only of recent years that any clear conception has been gained of the way it acts beyond the fact that it returns oxygen to the atmosphere. This is a necessary consequence of the splitting of the elements of water and the fixing of its hydrogen to a carbon chain. There is really only one fuel, and that is hydrogen. All our food is essentially but a fixed form of hydrogen, and all the energy which supports life is derived from its oxidation with the formation of water. The splitting is accomplished by Keilin's cytochromes (one at least of which contains iron) and Warburg's enzyme. This iron atom is alternately oxidized and reduced. Ferrous iron contains one more electron than the ferric, and it is the handing over of this electron which is the activator of a series of changes too complicated to describe here; we are shown, however, that it throws light on the pigmentation of Addison's disease.

Man cannot live without his adrenals; but why does he turn brown before dying? Many fruits such as pears and bananas also turn brown when dying, while lemons do not. The brown pigmentation is due to the oxidation by an enzyme of catechol derivatives, while in those plants that do not turn brown the process is inhibited by a strongly reducing substance containing two very labile hydrogen atoms; this is ascorbic acid, which Szent-Györgyi found so abundantly present in Hungarian red pepper. Presumably the reducing substance normally present in the adrenal cortex is similar, and thus we remain unpigmented. Catechol and ascorbic acid both contain a dienol group on which the transferred electron exerts its effect. In the absence of ascorbic acid the oxidation of catechol to a pigmented derivative is not inhibited and the patient turns brown.

Professor Danforth's fascinating lecture on genes and hormones contains so much of fundamental biological interest that it has been made the subject of a leading article elsewhere in this issue.

SENSATION AND THE PSYCHE

Psyche and the Physiologists and Other Essays on Sensation. By Edward Guy Dru Drury, M.D., B.S., D.P.H. (Pp. 98. 5s. net.) London: H. K. Lewis and Co.

Dr. E. G. Dru Drury's occasional addresses are sought and welcomed in South Africa, and they are known and highly appreciated by many medical practitioners and others in this country. He has recently collected six such addresses which he has delivered of late years and published them in a small volume. They will, in reading, give pleasure and profit to a wider circle than those who originally heard them, though the author's delivery must have added greatly to the enjoyment of his varied audiences, for they afford abundant evidence not only of an original mind but of a striking personality and a power of vivid verbal expression. They are no doubt most easily assimilable by select audiences of what may be called a university type, but not merely by members of the medical profession or faculty. Two of them—that which gives its title to the collection and that headed "What do we Think With?"—were given at the Rhodes University College, the former to its Scientific Society and the latter to its Philosophical Circle. Two of them, "Labels and Luggage," and "Visceral Disharmony," were given to medical audiences at meetings in connexion with the Medical Association of South Africa (B.M.A.); one, "On Boredom," was delivered to teachers; and one, "On Growing a New Claw," to a branch of the Trained Nurses' Association. All alike require a certain alertness of mind for their full appreciation; but, with this, readers even more than hearers will be able to enjoy Dr. Dru Drury's subtleties of thought and expression and the originality and novelty of his point of view. This originality and novelty constitutes the main value of his collected essays. It is combined with a facility of apt quotation from a very wide selection of the writing of others, and with an illustrative suggestiveness of metaphor which is usually equally happy.

The author's theme, which holds a certain unity throughout, is, as indicated by his titles, the connexion and relation between physiological sensation and psychological reaction; and, in addition to the enjoyment of the characteristic thought and expression to which attention has been drawn, any reader, be he medical or lay, should be able to derive some very practical and valuable lessons. The astonishing and rather gruesome account of "growing a new claw" in particular will not only provoke a real retrospective sympathy for the author in every reader, but demonstrates very vividly how the sufferings of a medical practitioner in his own bodily illness may lead to a profitable enlargement of understanding both in the physiological and in the psychological field.

CASE-TAKING AND PHYSICAL DIAGNOSIS

Workbook in Elementary Diagnosis for Teaching Clinical History Recording and Physical Diagnosis. By Logan Clendening. (Pp. 167; illustrated. 7s. 6d. net.) London: Henry Kimpton. 1938.

Dr. Logan Clendening, professor of clinical medicine in the University of Kansas, brought out in 1934 *The Laboratory Notebook Method in Teaching Physical Diagnosis and Clinical History Recording,* and, as the clinic is simply a laboratory of a slightly different kind, this new book is described as a somewhat expanded rearrangement of that notebook. The author is evidently a keen and experienced teacher and has here provided a clear and elementary guide for medical students at their entrance on clinical work. But it is so graphically illustrated by a picture gallery of methods of physical examination—for example, the deep grip palpation, fist palpation, and hammer percussion of Murphy, and testing for protopathic sensation—and also representations of the facies and gaits in disease, that there may well be an appeal to those whose undergraduate days are long past. Further, the sometimes dry bones of physical signs are made interesting by brief verbal reproductions of their original accounts, thus recalling *The Classical Descriptions of Disease* by his colleague Professor R. H. Major, to whom and others gracious acknowledgments are made. A postscript contains some aphoristic reliefs such as, "Physical diagnosis is an art; and the mastery of an art has no end. You can always be a better physical diagnostician, just as Paderewski could always become a better pianist or Leonardo a greater painter. . . . Even a reading of *Hamlet* will improve your percussion. . . . A brilliant but erratic physician was asked to examine a patient; he paused a yard from the bed's foot and said, 'What do you want to know about this woman?' 'I want a diagnosis,' said the intern, 'She has a tuberculous cavity in her left apex,' was the answer, as he passed on. His only explanation was that she always had a full sputum cup, and was always lying on her left side." No doubt such snapshot diagnoses are dangerous, but they illustrated some important principles of physical diagnosis, such as alertness of perception and logical deduction.

TUBERCULOSIS IN PRIMITIVE PEOPLES

Primitive Tuberculosis. By S. Lyle Cummins, C.B., C.M.G., LL.D., M.D. (Pp. 213; illustrated. 10s. 6d. net.) London: John Bale. 1939.

It is now universally recognized that in the development of tuberculous disease in man "soil" plays a part as important as "seed." In attempting to understand the interrelations between the tubercle bacillus and the varied resistance mechanisms in civilized races the study of tuberculous manifestations in primitive communities must therefore be of obvious value. Writing with the authority based on many years' work in the Tropics and experience as adviser and consultant to the Tuberculosis Research Committee of South Africa, Professor Cummins has performed a service in collecting the information available on this subject. An introductory chapter on wild and domestic life in relation to tuberculosis is followed by a discussion on the definition of "primitive" communities. Professor Cummins points out that words like "primitive" and "isolated" have no clear-cut or definite implications when used to describe human communities; they have a relative meaning only. After sketching the native outlook, he summarizes the work published in the past on tuberculosis of Africans, special chapters being devoted to investigations with the tuberculin test and to tuberculosis in South African natives. There follow sections dealing with the well-known investigations among the native miners of the Witwatersrand with which the author was very closely associated. He then reviews reports on tuberculosis in Africans who have temporarily left Africa, in Africans by descent or American Africans, in American Indians, in primitive tribes of various nationality, and in India. Short chapters are devoted to animal tuberculosis capable of affecting the human body, to B.C.G. vaccination, and to treatment. Finally Professor Cummins attempts to explain the differences in susceptibility found, putting forward his own theory after presenting various points of view hitherto held. He concludes:

> "One thing is certain: that the child, whether in our own race or in the primitive, is alike in having no acquired immunity. The type of disease is similar in the two when disease ensues. But disease nearly always ensues in the negro infant infected with the germ, whereas it is the common experience of our race to bring up healthy but tuberculin-positive children. One must talk with references to averages, and, while it is possible to produce exceptional cases, it is, on the average, easy for the infant of tried stock to elaborate immunity and overcome his infection, whereas it is hard for the primitive child to do so. And it is not only the child but the adult of primitive stock that give us the picture associated with childhood in this country."

The bibliography of 180 references will be found of great value, but it is a pity that a monograph containing so much quoted matter should not have been provided with summaries or conclusions at the end of each chapter. Attention must also be drawn to a typographical defect: in the latter part of the book particularly an unusually large number of words show misalignment of the last letter.

METEOROLOGY AND DISEASE

Essai de Météoropathologie: Physique, Clinique, Thérapeutique. By W. Kopaczewski. (Pp. 296; 14 maps; 26 tables. 50 fr.) Paris: J. B. Baillière et Fils. 1939.

In the introduction to his work on meteoropathology Dr. W. Kopaczewski states that though the part played by various meteorological factors in the appearance of certain pathological conditions has been realized since Hippocrates and emphasized by many subsequent writers, especially Pettenkofer, considerations of the kind have been completely forgotten since the advent of bacteriology, when the microbe became the sole criterion of health or disease. It is in opposition to such an exclusive view that the author has undertaken the present work, in which he emphasizes the important part played by meteorological factors in the causation of disease.

The book is divided into three parts devoted respectively to experimental work, the clinical aspects of the subject, and therapeutics. In the experimental section he discusses the physical data connected with the atmosphere, including chemical composition, degree of dispersion, electric potential, humidity and pressure, as well as the various solar rays. Physiological observations next receive consideration, and an account is given of the action on living beings of radiations according to the length of the wave and of the air according to its degree of dispersion. The author then describes various forms of simple apparatus for carrying out certain meteorological observations such as the determination of the temperature of the air, atmospheric pressure, rate and direction of wind, degree of humidity, and so on. In the clinical section, after a description of the regulating mechanism, including thermo-regulation, barometric regulation, hydro-regulation, electro-regulation and actino-regulation, the author deals with forms of acute meteorological shock liable to occur when the regulating mechanism is upset and the less dramatic morbid manifestations due to heredity or acquired predisposition to the action of meteorological factors. Lastly, in the section of therapeutics he includes an account of the various forms of climate in France illustrated by a number of hitherto unpublished charts supplied by the French Meteorological Office; hygiene, including clothing, housing, diet for predisposed persons; and the treatment of various pathological conditions. An international bibliography of 257 references is appended.

LOWER SEGMENT CAESAREAN SECTION

Caesarean Section: Lower Segment Operation. By C. McIntosh Marshall, F.R.C.S. (Pp. 230; 107 figures; 2 plates. 21s. net.) London: Simpkin Marshall, Ltd.; Bristol: John Wright and Sons, Ltd. 1939.

The author of this excellent book has performed 250 consecutive lower segment Caesarean sections with no maternal mortality. This is in spite of the fact that approximately one-third of his patients were infected or "suspect" before operation. He therefore writes with authority, and he writes well.

> "It cannot be denied that of the women who undergo Caesarean section more than two-thirds die, and barely a third are saved. Caesarean section belongs to those operations of which the outcome is entirely uncertain. Before, then, undertaking this procedure, one should allow the patient to draw up her will and grant her time to prepare herself for death."

The book opens with these words of Osiander and very appropriately ends with an analysis of Mr. Marshall's splendid results. The evolution of technique which in 200 years has converted a lethal operation into a life-saving one is admirably summarized. The anatomy of the uterus, and especially of the lower segment, during pregnancy, labour, and the puerperium is described in detail, and with this as a background the various possible incisions are discussed. The subject of anaesthesia is rightly given prominence. Mr. Marshall compares his experience of ether, spinal, and local anaesthesia with that of many other surgeons, and expresses the opinion that only by the persistent use of local infiltration can the operative mortality be reduced to a minimum.

Anaesthetic and operative technique are carefully described and admirably illustrated, and special attention is paid to the treatment of the infected patient. Readers are reminded that the third stage is of importance with Caesarean section just as with delivery per vaginam, and the methods of avoiding haemorrhage, or of controlling it when it does occur, are carefully described. The place of the lower segment operation in the treatment of placenta praevia is well discussed in a stimulating and slightly provocative chapter in which a reason, and usually an excellent one, is given for every practice advocated.

No obstetrician or surgeon who performs Caesarean section should fail to read this book. It has been most carefully prepared and arranged, is very well illustrated, and must take pride of place as the English classic on the subject.

Notes on Books

A fourth edition of *Hypertension and Nephritis*, by Dr. ARTHUR M. FISHBERG, is published in this country by Baillière, Tindall and Cox at 37s. 6d. This well-established work contains not only an admirable summary of the present knowledge of the subject with ample bibliographies but the result of much personal observation, especially at the Mount Sinai Hospital where the author works. The advances of knowledge in the interval have called for much revision; there is a new chapter on azotaemia, and additions have been made to many sections, for example, the experimental production of glomerulonephritis, the use of mercurial diuretics, the nephrotic syndrome in diabetes mellitus, and the treatment of nephrotic oedema by the intravenous injection of large volumes of acacia solution. Attention is fully paid to Goldblatt's experimental production of hypertension by constriction of the main renal arteries by clamps and the resulting renal ischaemia, and to the possibility that this explanation—namely, obstruction of the main renal arteries—may apply to some human cases without renal artiolosclerosis. The question of hypertension due to factors other than renal, such as adrenal tumours and pituitary basophilism (Cushing's syndrome) is considered. The author prefers the title "the malignant phase of essential hypertension" to the shorter one "malignant hypertension," and emphasizes that this phase is due to damage and necrotic changes in the renal arterioles and glomerular tufts caused by long-continued and very high diastolic blood pressure. He has given much attention to the descriptions of symptoms and the simple methods of diagnosis, and points out that a study of blood chemistry is necessary in a minority only of hypertensive patients.

Two years after the publication of LIONEL FIFIELD'S *Infections of the Hand* its promising author was killed in a motor accident. His thoroughly sound and workmanlike book has been a valuable bequest to many students, house-surgeons, and practitioners, and now a second edition is very welcome (H. K. Lewis, 9s.). Mr. Patrick Clarkson, who has been responsible for this second edition, has revised and rewritten several chapters and introduced references to the newer accessory methods of treatment such as sulphanilamide therapy and short-wave diathermy. He is to be congratulated on a revision which, while still possessing the background of Fifield's work, brings this thoroughly up to date. Mrs. Clarkson's line diagrams are clarity itself and add much to the attraction of the book. The chapter on insurance aspects and prognosis will be helpful to many. The book should be read by all house officers and young practitioners. There is still too much incorrect and inopportune treatment of injuries and infections of the hand through lack of that guidance which such a work as this admirably supplies.

Success with an earlier introductory work on general biochemistry has encouraged Professor ROGER WILLIAMS to write *A Text-Book of Biochemistry* dealing more particularly with animal biochemistry. This stands about midway between the very elementary introduction designed for readers new to the subject and the larger treatises containing a great wealth of detailed information, but it does not consistently maintain that position. In many places the treatment of the subject-matter is that of the first type, whereas elsewhere it offers an unusual amount of detail. For example, tabulated data relating to the composition of body tissues take up 15 pages. Such an array of figures is not in keeping with the expressed intention of the book, which is not to provide a storehouse of information but is, to quote the preface, "to *develop insight* . . . into the phenomena of biochemistry." On the whole the author has succeeded in his primary aim; the relevant facts are as fully discussed as is necessary to the fundamental understanding of the many phenomena brought under consideration; the mode of presentation, despite a number of vague statements, is attractive, and the author takes special care to explain difficult technical terms. He is at his best with the vitamins (sources and requirements are given close attention) and biochemical catalysts, and these sections, coupled perhaps with the brief but very instructive chapter on the chemical aspects of nervous control mechanism, would in themselves establish the book as one well worthy of attention. It is published by Chapman and Hall at 21s.

Professor **HANS KLEINSCHMIDT**, director of the Children's Clinic at Cologne, assisted by nine other writers from Cologne and one (Dr. Heinrich Heinlein) from Bonn, recently published an instructive work on poliomyelitis with special reference to the epidemic at Cologne in 1938. All aspects of the disease are considered, including history, aetiology, epidemiology, morbid anatomy, pre-paralytic and paralytic stages, examination of siblings and children in schools where cases have occurred. The number of cases in the Cologne district (including 399 with 37 deaths in the town of Cologne itself) amounted to 551 with 44 deaths. Apart from several cases occurring in one family, there were no instances of multiple attacks in the same houses, and no doctors or nurses caught the disease. As regards seasonal distribution, the disease appeared in the late summer and autumn months and rapidly declined in the last quarter of the year. Thus of the 399 cases in the town of Cologne there were only 14 cases between January and July, whereas there were 148 in August, 140 in September, 74 in October, and only 17 in November and 6 in December. As regards the occurrence of abortive cases, systematic examination of children who had been in contact with definite cases showed that one-third of the former presented marked changes in the cerebrospinal fluid, though clinical symptoms were trivial or entirely absent. Specific treatment either prophylactically or therapeutically in the form of convalescent serum was disappointing. In contrast with the results obtained in London with the Drinker apparatus, no benefit was derived with the artificial respirator known as Eisenmerger's biomotor during the Cologne epidemic. A bibliography of over 360 references is appended, of which only two are British. The publisher is S. Hirzel of Leipzig.

Congenital fragilitas ossium is the subject of another monograph by Dr. H. **FULCONIS**, who has not only analysed clinical and pathological material but has carried out certain experiments which lead him to suggest that current views on ossification in the normal subject require revision. He brings forward suggestions that there is a definite endocrine control of the laying down of calcium in the bones, and in the treatment of this condition of brittle bones he uses a diet of milk from animals which have been ovariectomized. There is much of interest for paediatricians in this slim volume, which is published in Paris by Masson et Cie at 28 fr.

Preparations and Appliances

LIGHT WHEELED CARRIERS

Dr. A. P. **THOMSON**, F.R.C.P., Commandant of the General Hospital, Birmingham, writes:

Stretcher bearing is heavy work, and to reduce the labour and increase the speed and smoothness of transport of a large number of stretcher cases from the casualty block of the General Hospital to the wards and resuscitation department the Raynal Manufacturing Company, Ltd., Woodburn Road, Birmingham, 21, have designed and made for us a number of the light wheeled carriers (shown in the illustrations) which have proved satisfactory in use. The weight of the carrier is 20 lb., and by means of clips it may be attached to a stretcher (either the old wood and canvas type or the new steel and wire one) so that two bearers can lift both with a patient over obstructions such as a small flight of stairs or a kerbstone. The carrier runs easily and will turn in its own length: one man can push it fully loaded on a smooth surface without difficulty for a considerable distance. It will stand by itself with the patient tilted slightly with the feet down, and even with four folds of blanket under him there is no tendency to slipping. A restless patient should not remain on the stretcher unattended as, although fairly stable, it can be overturned if the patient leans well over the side.

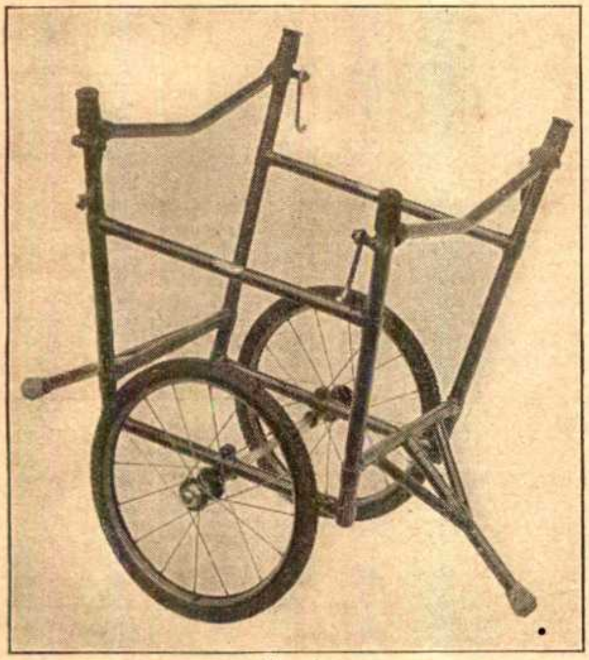

FIG. 1.

Primarily designed for use in large institutions, I believe the carrier would also be valuable in aid posts, general stretcher bearing on paved roads, and on railway platforms for the loading of ambulance trains. The carriers can be stacked in nests of three and occupy little space when not in use. Another type will be available shortly; fitted with more elaborate supports so that with a stretcher it may completely replace the heavy four-wheeled trolley; and (if there is any demand) one fitted with larger tyres and springs for use on rough roads and a collapsible carrier for transport in motor ambulances can be supplied.

CHEMOTHERAPY AND INFECTIONS IN WAR

It so happens that there was time enough between 1935 and the outbreak of war for extensive study of the action of prontosil and its derivatives in bacterial infections. Though many subsidiary questions in the clinical sphere of this study remain to be settled, and perhaps a few more fundamental problems on its theoretical side, there is now a solid foundation of experience by which intelligent therapy may be directed with a degree and certainty of benefit such as no previous remedy for the same conditions could approach. In present circumstances it is unlikely that further study, either experimental or clinical, will be able to proceed at the same pace, at least in Europe. The uncertainties and anxieties of war, as well as the manifold inconveniences which have been entailed even in preparation for it, impose conditions in which research is the first thing to suffer. What we are probably about to see is not an extension of existing knowledge so much as its application to new conditions. If the medical problems of this war are to be of the same nature as those which arose in 1914–18, we can name beforehand certain infections in which the advent of chemotherapy will alter prospects completely. Meningococcal meningitis will be shorn of most of its previous mortality. The period of invalidity from gonorrhoea will be greatly reduced, and if large numbers of troops are treated in hospital complete control of the patient and opportunity for the fullest possible study of the progress of the disease should lead to the final definition of an optimum plan of treatment; both the choice of drug and the method of using it are at present somewhat varied. If a pandemic of influenza visits us we shall know whether chemotherapy can control the septic pneumonia which caused innumerable deaths in the autumn and winter of 1918.

These and other problems of ordinary medical treatment may prove to be of secondary importance to that of wound infection. It is here that new observations will need to be made and new policies defined. Gunshot wounds, or anything equivalent to them produced by other means, are rare accidents in civil life, and there is singularly little published information on the results to be achieved by chemotherapy in the prevention or cure of infection in such cases. On the other hand, it is safe to predict on theoretical grounds and on the basis of other experience that certain results will be obtained. There need, for example, be no hesitation in assuming that haemolytic streptococcal infection of wounds will be controllable; this was a dangerous and disabling form of sepsis, and in chest wounds often fatal. Among the commoner and usually less dangerous flora of wounds, staphylococci are likely to survive most chemotherapeutic attacks, whereas coliform bacilli, *Proteus*, and *Pyocyaneus*, if they behave in a wound as they are known to behave in the urinary tract, will succumb. It will be a question whether the more rapid closure and healing of a wound possibly so to be achieved justifies such risk and discomfort as adequate chemotherapy entails. Perhaps the most vital question of all is that of the benefit to be expected in gas gangrene. There can be little doubt that sulphanilamide has brought this infection rapidly under control in some cases without the aid of other treatment; no one acquainted with the facts would fail to administer this treatment; and we welcome the recommendation given in a War Office memorandum (published at page 834 of our last issue) that all wounds which appear likely to become the site of infection with gas gangrene should receive a prophylactic course of sulphonamide compounds at the earliest opportunity. How far it should replace amputation is another matter; and another on which clear guidance will be needed is the proper sphere of chemoprophylaxis. This question applies not only to gas gangrene but to wound sepsis generally, and in time it will doubtless be known whether it is the best policy to give every casualty a short immediate prophylactic course, or in certain types of case at least to await events.

In meeting the demands of these new conditions the soundest guide will be a thorough knowledge of the established facts of past experience in chemotherapy. Personal experience is helpful up to a point, but the reasoned conclusions of investigators with special opportunities from all over the world should not be ignored, and whereas most of these have hitherto been available only in original papers, they have now been ably collected and summarized in book form by Perrin H. Long and Eleanor A. Bliss of the Johns Hopkins University, Baltimore.[1] For reasons already suggested, this review of the past four years' developments may have a less ephemeral value than might have been expected. It covers the whole field—historical, theoretical, experimental, and clinical—and whether dealing with the disputed mysteries of how these compounds act or with the simpler facts of how or when they can best be used, the available knowledge is presented in a full but easily assimilable form. Each infection and each manifestation of it is separately treated, so that information can readily be found about the treatment of almost any type of case. The authors express decided personal opinions on matters within their own experience, and though everyone may not agree with all of these, no one will deny that the judgments expressed are in the main well informed and amply founded. To have condensed so vast a body of data into readable but sufficient form is no small achievement, and those who regulate their use of the new chemotherapeutic compounds in accordance with the principles and the detailed instructions here laid down will have good cause to be grateful for such guidance.

GENES AND HORMONES

Co-ordination of the results arrived at in different fields of knowledge becomes ever more difficult with increasing specialization, the worker in one field knowing little of what is being done in another, so that advance along a united front is delayed. It was unfortunate that Sir Albert Seward's presidential address to the British Association was delivered on the very eve of war, thus not receiving the attention it deserved. An acknowledged expert both in geology and botany, he turned his life work on fossil plants to good account not only by resurrecting the legendary lost continent of Thule as a scientific reality, but by illustrating the great advantage of combining two methods of approach to a problem. In the same way Professor Danforth in the Harvey Lectures, reviewed elsewhere in this issue, shows that pooling the results obtained in genetics and endocrinology gives us a clearer and more harmonious view of some important biological processes. The basic phenomenon of genetics is believed to be the independence and discreteness of the individual gene. Reproducing itself precisely except for rare mutations, immortal on Weismann's theory, it emerges from each new combination as pure as an atom released from a chemical compound. Genes and cytoplasm may be regarded as symbiotic, the gene influencing the reaction of the cytoplasm to both internal and external stimuli. Hormones may be regarded as activators, but can only act through such protoplasm as will respond to them. The same is true of organizers in the embryo. The specificity of most of their reactions apparently depends more on the receptive capacity of the tissue than on the hormones themselves. It is largely a question of whether or not the tissue will utilize the hormone if it is available. Their effects, if sometimes scarcely less profound, are generally more transient than those of genes. The evolutionist is intrigued by the fact that certain synthetic products can produce similar results. He begins to suspect that a hormone may antedate phylogenetically any adaptation of the tissues for its use. We are reminded of the hermit crab that seizes on an empty whelk shell. The crab was in existence before it found a suitable local habitation. Again, the presence of oestrogens in the coal measures greatly antedates the first appearance of mammals on the earth. Presumably they were first evolved by the plants, and the reason that they are oestrogens at all is inherent in the cyclic character of plant growth. Perhaps we have been prone to draw too sharp a line of demarcation between hormones and vitamins, and between both of them and simple chemical and physical factors on the one hand and genic influences on the other.

The biological advantage of sexual reproduction used to be attributed to a fresh blending of protoplasm and nucleus in the cell. Professor Danforth points out an additional advantage; in parthenogenesis identical genes would be thrown into direct competition with one another in the struggle for existence, with consequent extermination, whereas mixture of genes may lead to improvements perpetuated by natural selection. Without sexual reproduction it is doubtful if the kind of protoplasm which early appeared in the world could ever have reached the high degree of differentiation which the interaction between cytoplasm and new combinations of genes will favour. Botanists long ago pointed out the sequence from zoospore through isogamous gametes to heterogamous gametes and finally to ovum and sperm cell. Sex started as a difference between germ cells and has evolved into a difference between individuals. Indeed, the differences found in various species strongly suggest some such evolutionary sequence. In a vast array of lower animals the stage persists at which each individual may produce either sperm or eggs; age or season may determine which. This is particularly noticeable in the molluscs, where there is a widespread tendency to protandry which in young individuals is capable of overriding the normal female pattern of chromosomes. But when the animal reaches full maturity the chromosomal pattern overcomes the protandry, which, it is suggested, depends on humoral influences. This is strikingly substantiated by the recent studies of Moewus on reproduction in a species of *Chlamydomonas*. Kept in the dark they are without cilia and reproduce vegetatively, but if brought into the light they develop cilia and motile gametes. This will occur even in the dark on the addition of filtrates from cultures grown in the light. If the cultures are grown in red or orange light an inactive form of filtrate emerges. If this is subsequently exposed for a few minutes to blue or to violet light it can activate female gametes, and, then, after another inactive phase, male gametes, after which it remains completely and permanently inactive. Identical results can be obtained in the dark by merely adding a carotene derivative allied to vitamin A. Thus sex seems to be determined by chemical environmental factors in a number of lower forms of life. Such manifestations are suggestive of the hormonal activity seen in higher forms. With some birds certain of these characters seem to be almost completely under hormonal control. Among mammals there is the well-known example of the "free-marten," and sex reversals have been experimentally obtained in mice and rats. In human beings virilism of hormonal origin is clearly recognized. That some such changes can be induced apart from direct interference with the gonads is clear. A piece of skin transplanted at hatching from a male to a female dwarf turtle-dove produces male feathers over an area which goes on increasing. This can only be due to genes and cytoplasm descended from the original transplant, and evidently the female produces no hormone whose action opposes them. A similar experiment in the pheasant produces feathers which are a compromise between male and female plumage, while with the brown Leghorn fowl the feathers are always those of the host. In other words, in the dove sex differences in plumage are regulated by genes without reference to hormones, whereas in the Leghorn they are regulated by hormones without reference to genes. In the pheasant both factors must be operative.

The conclusion seems to be that the gene can influence the chemical make-up of the cytoplasm. In evolution the rearrangement of genes that has been found most advantageous for increasing that influence is the one provided by sperm and ovum. The growing complexity of the resulting protoplasm enables it to react to appropriate extraneous chemical substances. Important among these are the vitamins for which the cell has acquired a need in the course of evolutionary development, and the hormones based on pre-existing chemical material which the body has evolved the capacity to synthesize. These substances may in their turn reinforce the activity of the genes, though in some cases they may diminish or actually override it. Evidently there is close interaction throughout. It is not irrelevant to recall Witschi's observations on the abnormalities of growth brought about by experimentally delaying the fertilization of frog's eggs. The change of the chromosomal pattern and the interference with the chemical organizer thus induced give rise to bizarre types of cells, which in extreme instances acquire the characteristics of malignant growths. Pathological reactions are, after all, special instances of physiological ones induced by some abnormality in the external or internal environment. Only by a fuller knowledge of the normal processes of growth shall we be able to comprehend the nature of malignant growths.

FOOD AND A FIT NATION

In his three Harben Lectures delivered on successive days in the third week of October under the auspices of the Royal Institute of Public Health and Hygiene Sir John Boyd Orr made an extended reference to the importance of nutrition in war time, and recalled instances of the breakdown of nations at war not primarily as a result of military pressure but because of lack of food. The Allies, he said, must win this war at whatever cost; but while armaments were important they were of no use unless there was a fit nation to assemble and employ them. Therefore the feeding of the people in war time became of the greatest importance. It would be disastrous, he said, even from the immediate point of view of the war, if the big improvements in health and physique which had taken place in recent years were not carried further and consolidated. An increased consumption of protective foodstuffs was necessary. The urgent thing was to provide more dairy produce and more fruit. The capacity of the country to produce in these directions had never been anything like fully exploited. Production could be enormously increased, not only on farms but in gardens and allotments, even down to planting lettuces in window-boxes. If the people understood the need, said Sir John Orr, and put themselves to it, the result would astonish agricultural experts. The real aim of the war was something much wider than the destruction of Hitlerism; it was the establishment of international conditions under which the great achievements of science could be used in the creation of a golden age of liberty and peace. In that golden age the primary object of all Governments should be to ensure that a diet fully adequate for health was available to every individual so that he might be able to realize his full capacity for mental and physical fitness. In spite of the preoccupation of national energies in war, the work towards this great objective should by all means be pursued.

In the earlier part of his lectures Sir John Orr said that surveys which had been made in different parts of the world had revealed that people of all nations and classes were on diets which were in some way deficient. On the other hand, medical research had discovered a great new "gold reef" of knowledge with regard to protective foodstuffs. Therefore the campaign had shifted to the economic and educational fields to ensure that these foodstuffs, which were relatively expensive, were made available to the whole community, and to bring the knowledge of them into every household. In this connexion he gave a word of high praise to the British Medical Association on its campaign, started six years ago, towards better nutrition, and for all that its Nutrition Committee had done, by conferences and other means, to instruct both the medical profession and the lay public. As a result of the "big push" in nutrition, through the education of the public, the raised standard of living, the efforts to keep the cost of essential foods low, as well as through various public health measures, notably the provision of milk for school children, the common diet in this country had improved out of all recognition. The striking fall during the last ten years in the infant mortality rate and the tuberculosis rate and the considerable disappearance of deficiency diseases among children must be attributed largely to this cause. Sir John Orr thought that the medical profession deserved great credit for what had been done. It was the profession, especially those members of it who were engaged in preventive medicine, which was able effectively to apply the new knowledge. It was sometimes said that the better health of the people meant the disappearance of the doctor. That was not the case at all. It would require a larger number of doctors, exercising a higher degree of skill, and spending more time over their work, to ensure the prevention of disease and the detection of the earliest deviations from normal health than it would require to deal with gross diseases once these had developed.

THE KENNY TREATMENT OF POLIOMYELITIS

The Kenny method of treatment of infantile paralysis was subjected to a thorough test at the Queen Mary's Hospital, Carshalton, in 1937–8.[1] A report by Mr. Kenneth Starr[2] has now been published upon the experience gained in the Kenny Clinic and in the hospital at Newcastle, New South Wales. The conclusions do not differ appreciably from those of the Carshalton report. Seventy-five of the 114 cases referred to showed actual paralysis, and in some of them it was possible to carry out very early treatment even during the acute stage. The patient was rested in a standard position but without fixed splints, was kept very warm, and was treated by hot baths (without cold douches) and by active and passive movements so far as was possible without producing pain, these movements being given twice daily. The results claimed are a rapid abatement of pain and disappearance of muscle spasm, improvement in the muscle circulation, early return of full range of movement, and restoration of active movement in the non-paralysed muscles, together with diminution in the subsequent stiffness of the region affected. These results, if they are confirmed, are valuable, but unfortunately the amount of pain and muscle spasm varies greatly in different cases and in different epidemics, so that further experience is necessary. It is clear that the Kenny method does not lead to recovery which would not occur under other treatment. Its advocacy of the complete abandonment of splinting is not justified, but there is no doubt that in the hands of many orthopaedic surgeons splinting has been carried out too rigidly, with the result that movement and re-education have been delayed and stiffness increased. Miss Kenny's methods of hydrotherapy are good, but she does not take full advantage of the possibility of re-education of muscle in water. And she refuses to make use of the re-education board as a method of exercising muscles with the elimination of gravity. Mr. Starr's report criticizes strongly Miss Kenny's advocacy of early weight-bearing. Her claim is that this helps to restore muscle function. It is, however, contrary to the principles that have been advocated by most authorities, and there is no doubt that weight-bearing before the muscles are prepared for it may actually delay recovery, quite apart from the risk of damage to joints. It is rather remarkable in this connexion that the report does not refer to the use of supporting appliances. An interesting reference to muscle stiffness suggests that in this there is, first, oedema of the muscle followed by fibrocellular reaction with adaptive shortening, leading to a definite fibrosis. In the Kenny method this is combated by stimulation of the circulation by hydrotherapy and hot fomentations and by active and passive movement. According to this report these movements have a very definite success; in this one respect it is not altogether in accordance with the experience at Carshalton. The muscular stiffness is seen in muscles which are incompletely paralysed and have potentialities of recovery. It seems to be independent of splinting or immobilization, occurring sometimes in cases in which this has never been used, and its duration appears to be little affected by treatment. The Kenny method, like so many that are alleged to be new, includes points that are proving good and others that are not. It has acted as a stimulus to further work and made those who are concerned with the treatment of infantile paralysis review and revise their methods and organization. In this way it has undoubtedly led to improvement.

[2] *A Report to the Minister for Health, N.S.W., on Sister Kenny's Method of the Treatment of Infantile Paralysis.* By Kenneth W. Starr, M.B., B.S., F.R.C.S., F.A.C.S.

PREGNENINOLON

Earlier this year we discussed in these columns[1] the chemistry and first clinical reports on the use of an orally active form of progesterone which had been discovered by Inhoffen and Hohlweg,[2] and to which the name "pregneninolon" had been given. In a series of more extensive biological investigations at the National Institute for Medical Research, Hampstead, Emmens and Parkes[3] find that, as with so many of the sex hormones and analogous chemical compounds, pregneninolon is remarkably versatile in its actions. It is equally effective when given by the mouth or subcutaneously in producing progestational changes in the uterus of the immature or ovariectomized rabbit previously sensitized by injections of oestrone. Moreover, it exerts a trophic effect on the non-sensitized uterus of the immature or ovariectomized rat or mouse. This metrotrophic action is similar to that of oestrone and testosterone, and it is not altogether surprising to note that, according to these authors, pregneninolon has an oestrogenic action on the vagina of the spayed rat or mouse and an androgenic action on the comb-growth of the capon. They find that only in the case of its oestrogenic activity is pregneninolon less effective by the mouth than by injection. Quantitatively pregneninolon is ten times less powerful than progesterone in bringing about the progestational changes in the uterus of the rabbit. As an oestrogen it is about 3,000 times less active than oestrone, and as an androgen sixty times less active than androsterone. The probable effect of pregneninolon on the human subject is difficult to assess from these results, since it is well known that there is a large variation in the response of different species to oestrogens and androgens which is in no way related to the differences in body weight. Also the varied solvents that were used would effect the quantitative response. It appears, however, that the clinical doses of pregneninolon are unlikely to have oestrogenic action, and that the possibility of androgenic effects must be considered. Only further clinical experience can decide whether pregneninolon medication over long periods will have such undesirable results. Emmens and Parkes throughout their paper refer to pregneninolon as anhydro-oxy-progesterone; it has also been referred to as ethinyl-testosterone. Such a multiplication of nomenclature is to be deprecated. The name "pregneninolon" was given to this compound by the discoverers, Inhoffen and Hohlweg, and this should be retained until a change, if desirable, is agreed upon internationally. The term "anhydro-oxy-progesterone" is also misleading in that it uses the German prefix -oxy rather than the usual English -hydroxy.

BOOK ON WAR SURGERY

The articles appearing each week, from April 15 of this year until the present issue, on the treatment of war wounds and air raid casualties, have been read with close interest and approval both in this country and in the Dominions and Colonies, as is evidenced by the numerous letters we have received, some of which have appeared in our correspondence columns. There have been many requests that the series should be reprinted in book form, and before the outbreak of war steps were taken to put this in hand. Publication has been undertaken by Messrs. H. K. Lewis and Co., Ltd., 136, Gower Street, London, W.C.1, and the volume will be on sale in about a week's time or less (price 10s. 6d.). The early papers in the series were based on lectures delivered at the British Postgraduate Medical School, and these were followed by supplementary articles, contributed by invitation, on psychological casualties, on the medical aspects of chemical warfare, and two articles contributed by medical officers of the Ministry of Health on the organization of the emergency medical services. That on the organization of aid posts proved to be highly topical, and much interest has been shown in the two contributions on war surgery in Spain. War or peace, the essential unity of surgery remains, and the volume now to be published should be looked upon as a companion to the third volume of *Treatment in General Practice,* on anaesthesia and surgery. The surgical series will be resumed in our next issue.

COMPARATIVE MEDICINE

Dr. Louis Bory belongs to the very small band of practising physicians who have taken an interest in the diseases common to both the human race and other animals. A distinguished dermatologist in the first place, it is now many years since he was struck by the importance of comparing the skin diseases of animals with those of mankind, and to that end became an assiduous student at the great French Veterinary College of Alfort. Three years ago, in collaboration with Professor Henry of that institution, he published an essay on comparative dermatology which has had the honour of being included in the Nouvelle Pratique Dermatologique, the great achievement of the French School, which centres round the Hôpital Saint-Louis. He has now produced a more comprehensive work on comparative medicine in which not only cutaneous but diseases affecting other organs are discussed.[1] He includes in his survey both those disorders which attack the animal world spontaneously and those which are inflicted on it by physiologists and pathologists in their search for the solution of some problem of human medicine. Dr. Bory emphasizes the essential unity of human and animal pathology—a unity which is usually neglected by the practising physician, perhaps with some justification, for the modern medical education is sufficiently comprehensive and exhausting without adding to it a course of instruction in veterinary science; but there is no doubt that he is right in saying that every medical man who decides to dedicate himself to research should spend no inconsiderable time in the study of animal and indeed also of vegetable disease. His monograph is gracefully written and deserves to be read by all who are interested in the philosophy as well as in the practice of medicine.

BRITISH SPAS IN WAR TIME

The exigencies of war have, as is well known, placed the spas in a difficult position, and the executive of the British Spas Federation met on October 17 to consider the situation. The British spas are maintaining their bathing establishments in full working order. All treatments and the services of the trained staffs are available as usual. The taking over of spa hotels, which has been the subject of such severe criticism, immediately placed invalids in a very serious position. All the British Spas—Bath, Bridge of Allan, Buxton, Cheltenham, Droitwich, Harrogate, Leamington, Llandrindod Wells, Strathpeffer, and Woodhall Spa—have made arrangements for dealing with difficulties of accommodation, and, contrary to what may perhaps be thought, it is usually possible to meet the requirements of prospective "cure visitors." Such invalids should communicate with the director or manager of the spa they require, or if in further doubt or difficulty with the honorary secretary of the British Spas Federation, either at the Pump Room, Bath, or at the Travel Association Information Bureau, 28, Cockspur Street, London. At no time have the facilities provided by the spas of Britain been more needed. In their equipment and organization and in their general character as health centres the spas have a unique contribution to offer towards maintaining the health of the civil population, and later in restoring the wounded and invalided.

The William Mackenzie Memorial Lecture, on perimetry and the visual pathway, will be delivered by Dr. H. M. Traquair in Faculty Hall, 242, St. Vincent Street, Glasgow, to-day (Saturday, October 28) at 4 p.m. Sir Robert Wilson, president of the Glasgow Eye Infirmary, will take the chair, and Dr. John Henderson, President of the Royal Faculty of Physicians and Surgeons of Glasgow, will present the Mackenzie Memorial Medal to Dr. Traquair.

WAR WOUNDS AND AIR RAID CASUALTIES

The following article is a supplement to the lectures on war wounds and air raid casualties. It completes the series, which will now be reprinted in book form

DETONATION OF HIGH EXPLOSIVE IN SHELL AND BOMB, AND ITS EFFECTS

BY

DAVID DALE LOGAN, D.S.O., M.D., F.R.F.P.S.G., D.P.H., M.I.M.E.

Lieutenant-Colonel, R.A.M.C. (Ret.)

PART II

When shells and bombs burst in the open carbon monoxide, with its specific gravity of 0.96 (slightly lighter than air), is quickly dissipated, which makes it useless in offensive gas warfare. In deep trenches under favourable (that is, dull heavy) atmospheric conditions, violent and prolonged bombardment may cause a collection of CO high enough to cause poisoning. British, French, and German observers have proved this by finding CO in the blood of men killed or wounded during the shelling and by observing symptoms of poisoning—headache, giddiness, sickness, loss of consciousness—in a number of those exposed. These symptoms were generally regarded by the men as the result of the noise and the shock of shells bursting in their vicinity. Carbon monoxide has also been discovered in the blood of men killed by the bursting of shells which, though close to them, had caused no apparent wounds; and in the blood of men found in a state of shock under similar conditions. This has been confirmed by French and German investigators.

CO Poisoning from Detonation

Before it was generally recognized that CO poisoning in dugouts and in other enclosed places may follow dense salvos of high-explosive shells, cases of fulminant gas poisoning from detonation of heavy shells, used in 1916 on a vastly increased scale, gave rise to the belief that the different combatants were using a new asphyxiating gas. This idea was strengthened by the fact that all respirators then, as now, gave no protection against carbon monoxide. In a German pamphlet, issued as late as 1918, it was found that the enemy felt it necessary to allay fears prevalent among their troops that the Allies were using a new gas. "The use of special poison gas by the enemy—for example, prussic acid—has not, up to the present time, been definitely confirmed. Cases of death attributed to prussic acid are mostly due to carbon monoxide poisoning."

A shell or bomb bursting in or near a confined place produces large quantities of irrespirable gases which may displace the oxygen content of the atmosphere. In those exposed death may occur very quickly from the deprivation of oxygen as well as from the inhalation of carbon monoxide, the action of which, under these conditions, becomes intensified. Indeed, in such circumstances death may be instantaneous. In dugouts groups of men were frequently found dead, overwhelmed by gas before they were able to make a movement. German officers were found dead while playing chess, one dying just as he was making a move. The sole cause of death in those who were found in dugouts at a distance from the burst was carbon monoxide. During the war a writer in the *British Medical Journal,* discussing these sudden spectacular deaths in dugouts, held that in a number "the true cause was the sudden snatching away of the atmosphere pressure in and around the bodies by the voracious vacuum suddenly produced without." The explanation of this will follow later.

Thousands of soldiers have been poisoned by gas from shells bursting in or near the entrance to dugouts, subways, or cellars, which, under the conditions, ceased to give effective shelter and became mere death traps. Many examples were afforded during the Somme offensive in 1916 and during the French and British offensives of 1917. The following classic examples will give some idea of the dangers:

The Cumont-Mort-Homme tunnel, occupied by the Germans, accommodated brigade headquarters, two battalion headquarters, an aid post, and a kitchen. During the French bombardment both tunnels became crowded with wounded and stragglers from various units. The bombardment blocked all the entrances, and the galleries were flooded with fumes from the high-explosive shells, which asphyxiated most of the occupants, a considerable number of whom died. Six hundred survivors were taken prisoners.

The Tunnel Cornillet, held by the Germans, was composed of three galleries each a thousand feet long and eleven feet broad. There was an exit from each gallery. Ventilation was obtained from hand fans and from a number of ventilating shafts in the roof. There was accommodation for three battalions. During the French attacks salvos of shells bursting near the entrances, already sealed by the explosions, gassed the pioneers and prevented them freeing the entrances. Next day a large shell penetrated the tunnel doing great damage, and another came through the ventilating shaft. Many of the garrison were poisoned by carbon monoxide, and a large number died. The rest were so demoralized that no attempt was made to clear the entrances. Many prisoners were captured. In this case very few deaths were caused by direct violence. The vast majority were the result of gas poisoning.

How Such Accidents were Prevented

In modern trench warfare and aerial warfare adequate underground protection is all-important. The British defence on Givenchy Ridge in April, 1918, forms an excellent example of how the effects of intense shell fire on dugouts may be combated and supports Professor Haldane's plea in *A.R.P.* for deep underground protection.

Several attempts were made by the enemy to capture the Ridge, each attack being preceded by heavy shelling, which, however, failed to crush the entrances to the deep dugouts. Three of the entrances were protected by ferro-concrete monoliths, each with a minimum thickness of four feet; one entrance was in a cellar strengthened by rails and a bursting course, and three other entrances were covered by elephant shelters with a triple course of rails and five feet of broken bricks as a bursting course. Gas, either from explosives or from gas shelling, was prevented from gaining admission to the dugouts by efficient gas curtains and gas doors. The troops were thus perfectly safe, as was abundantly proved by the success of the counter-attacks which cleared the enemy off the high ground.

Gas from the detonation of shells, bombs, mobile charges, minenwerfers, etc., has been known to gain an entrance into cellars and dugouts at some distance from the burst through fissures in the strata or through cracks in the walls of the buildings. In an intensive bombardment by heavy shells or by bombing, the ground in the affected area may become saturated with gas. This is more likely to occur if there has been imperfect detonation of the explosive, or if heavy shells and bombs with time-fuses have penetrated so deeply that when detonation occurred no craters formed. In all these cases gas may find its way into cellars, basements, or dugouts by percolating through the porous ground or through crevices formed in the ground. It is well to remember that when gas percolates through soil it loses its distinctive odour and becomes all the more insidious.

On the Western front hundreds of deaths from CO poisoning resulted from the detonation of mobile charges used for destroying dugouts and subways. The following is a good example of what happens, and it also shows the great value of efficient rescue work.

Preliminary to a hostile raid there was an intense bombardment of the British front line trenches. The ventilation of the infantry tunnel was seriously disturbed by the detonation of minenwerfers which crushed in two of the entrances. Shortly after shelling stopped the entrance to the shaft leading to the tunnel was blown in by a mobile charge brought over by the enemy raiding party. A demolition charge of our own which was in the shaft mouth was fired by the action of the enemy charge. Of thirty-six men who were in the tunnel, twenty-five lost their lives by CO poisoning before they could be rescued. Mine-rescue men with apparatus were quickly on the scene and succeeded in rescuing and resuscitating eleven men, all of whom were unconscious and seriously affected. All these men required oxygen, most of them artificial respiration. In two cases oxygen administration was kept up for ten hours. All recovered. The enemy mobile charge which detonated our charge at the shaft mouth had given rise to large quantities of gas.

It is well to remember that very often more gas is given off when explosives in large quantity are fired in the open than when the explosive is fired after being properly tamped. The fact that ventilation, owing to the entrances having been previously crushed in, was defective would accentuate the action of CO, and the presence of even small percentages of CO would, under such conditions, have serious consequences.

Many cases similar to the above were caused during the frequent British raids on the enemy lines, the tunnellers, who accompanied the infantry, carrying over very heavy mobile charges of high explosives. Owing to the high concentration of CO in these cases, and to the difficulty of setting up good ventilation, the entrances having been destroyed, death would follow very quickly. In some places where there was incomplete detonation of the charges, nitrous fumes as well as CO were formed.

Cause of Death in Concrete Shelters subjected to Heavy Bombardment

Recently questions have been asked regarding the effect on the occupants of concrete shelters of severe concussion from the detonation of bombs. Although aerial bombing, owing to the considerable intervals between bursts, is entirely different from intensive bombardment by shells, it is interesting to recall some experiences during the war.

The nature of the ground on Messines Ridge, where there is a water-bearing sand about twenty feet below the surface, made the construction of dugouts impossible. Ferro-concrete shelters were therefore used and proved of the greatest value in resisting shell fire. A large proportion escaped serious damage, although the entrances were blocked. It is very questionable if the occupants of these concrete shelters could remain in a condition able to fight, or even to survive under repeated concussion from the bursting of heavy shells. It was quite common to find the occupants dead in shelters which had been hit, but not penetrated, by eight-inch shells. In these cases there was no question of gas. A number of these shelters in the village of Messines were practically intact, and yet the wood lining and everything inside was shattered into many pieces, showing that the concussion must have been terrific. Anyone who has experienced, as I have, machine-gun fire in a "pill-box" knows the painful effect the concussion has on the ears, and this would be many times less than the effect of heavy shells landing. Commotio cerebri would be caused by the intense vibrations being transmitted through the bony structures to the central system. Various methods were adopted to lessen the intensity of the shock, but without success. After their painful experience at Messines and Langemarck it was quite common for the enemy to leave the pill-boxes during heavy shelling, and get into neighbouring shell holes, returning to the pill-boxes when the barrage lifted.

Immediate Effects of Detonation of High Explosives

It is very necessary to understand what happens when a large shell, trench mortar, bomb, or mobile charge explodes. Before considering this I should point out one great difference between shells and bombs or mobile charges. The high-explosive content of a projectile from a gun is greatly reduced by the thick walls of the shell which are necessary to withstand the shock of discharge. The mobile charge or the bomb, on the other hand, is nearly all high explosive.

When a charge of high explosive is detonated there is, first, an enormous expansion of gas. This is referred to as expansion, or explosive wave, or simply as blast, and corresponds to the French "vent du projectile." This is followed by another wave, a tremendous inrush of air, which has been variously described as recoil, suction, or aspiration. Sir Frederick Mott, from the various pathological findings, refers to the first as the wave of compression, and to the second as the wave of decompression. Some observers hold that the latter has even greater destructive action on the human body than blast.

It is not necessary in this article to describe the extraordinarily varied effects of bombing on buildings in cities and towns. This has been very vividly described and minutely detailed by Professor J. B. S. Haldane, John Langdon-Davies, and other writers from their recent experiences in the Spanish War. In order to illustrate the two explosive waves, let me quote Professor Haldane in his most interesting and informative work, *A.R.P.*, which I advise all doctors to read. He describes how, when bombs burst in a Spanish street, the metal shutters of shops which had not been knocked down were sucked outwards, and when a bomb fell inside a house a large part of the shattered walls fell inwards.

Diagram of the Effects of an Explosive Wave

NEUROSES
CO. POISONING IF THIS ZONE IS AN ENCLOSED SPACE
CO. POISONING IF THIS ZONE IS AN ENCLOSED SPACE

Note.—The size of the zones A and B will depend on the amount of explosive in shell or bomb.

By far the greatest number of casualties resulting from detonation of heavy H.E. shells and bombs is caused by flying pieces of shell, brick, stones, and debris, which are impelled at great velocity and may cause death hundreds of feet from the exploded bomb or shell. A considerable percentage of the casualties are caused by crushing, by burying, and by asphyxiation from the collapse of buildings, entrances to cellars, dugouts, etc. Inside the zone of maximum violence bodies may be torn to pieces and mutilated by the force of the explosion. Men may be hurled by the force of the explosion and smashed against buildings or against the ground.

Wounds produced not by missiles but by the explosive waves may be produced (*a*) from without inwards, this due to the enormous compression and velocity of the gases (the explosive wave travels many times faster than the fiercest hurricane), or (*b*) from within outwards, during the recoil.

To give some idea of the intensity of the blast, Sir Frederick Mott, in his book *War Neurosis and Shell Shock*, quotes the American Medico-Military Report, which stated that an "aneroid showed that the explosion of one of these shells caused a sudden atmospheric depression of about 350 mm. of the mercury tube, corresponding to a dynamic pressure of about ten tons to the square yard."

There is no doubt that many cases of sudden death, where no wounds were found, were caused by the severity of the blow over the heart or epigastrium. Sir Frederick Mott believes that the enormous aerial compression "may be transmitted to the fluid about the base of the brain and cause shock to the vital centres of the floor of the fourth ventricle, causing instantaneous arrest of the function of the cardiac and respiratory centres." This, he held, explained many of the cases of sudden death where there were no visible injuries to the body. In describing a personal experience of his own during the war when he was in the vicinity of bursting shells, Professor Haldane thought that death in some similar conditions might be due to paralysis of the breathing.

The second, from within outwards, explains the bursting open of cavities as well as the extensive and strange character of the wounds occasionally noticed in the vicinity of explosions. After the bursting of large shells, bombs, and trench mortars near dugouts or cellars, the parts of the body which would be affected by the suction are those which contain gas, and one would expect to find conditions similar to those produced in accidents in caissons but more exaggerated.

Langdon-Davies, in *Air Raid*, describes how many bodies were found which did not bear a mark of any wound. Mitchener and Cowell have also described similar casualties caused by bombs exploding in narrow streets. On post-mortem examination the lungs were found to be torn and the abdominal viscera ruptured. Early in the great war Adrian Stokes, the famous pathologist, described to me extensive haemorrhages in the lungs with no visible wounds. In the official *Medical History of the War* (vol. i, p. 46), in describing the effect of a trench mortar bursting near a signal dugout in which two signallers were working, the contributor stated that

> "nothing more was seen of either of these men except one of the lower extremities, which was hanging on the German wire about 150 yards away. It had been disarticulated at the hip-joint. The number of men who have completely disappeared during the war, and whose deaths have had to be presumed, suggests that these disruptive effects are by no means rare."

As I have already pointed out, a number of the deaths of occupants of dugouts, especially of those at a distance from the burst, were due to CO. This gas is most insidious in its action. A good example of this was afforded when, during the work of clearing the ruins in Ypres, the bodies of forty British soldiers were discovered in cellars in the Grande Place. Some of the bodies were badly mutilated; those in other parts of the cellar were lying in peaceful attitudes, obviously poisoned by the fumes from the detonation of a large shell.

In experiments carried out in France to discover the effect of detonating 20-lb. charges of ammonal in dugouts, dogs were placed in various positions in these dugouts. Those within the zone of maximum violence were blown to pieces or killed outright by the force of the concussion without showing any injuries, while at a distance some were killed by CO and others seriously affected by it. This is very similar to experiences in the trenches when canisters of high-explosive demolition charges were used to drive out the occupants of dugouts.

Although I have pointed out some of the dangers of shells, bombs, and mobile charges bursting in or near dugouts, cellars, buildings, etc., it must be remembered that in modern warfare life would be impossible without adequate underground shelters, and that these undoubtedly saved many thousands of lives during the great war. In an article in the *Spectator* in February, 1939, I pointed out that

> "the experience of the war and recent experiences in Spain proved that nothing so quickly gives confidence and allays panic in heavy bombardment by high-explosive shells and bombs as the provision of efficient underground shelters. The imperative duty of the Government is the adequate provision of large underground bomb-proof shelters in those cities and towns which are likely to be attacked. Underground accommodation for hospitals on a large scale should be commenced at once. The bombing by the Germans during the war of the crowded hospitals at Etaples may be remembered by many; I saw the ghastly results. Hundreds of the patients, doctors, nurses, and staff were killed or wounded."

These opinions, I may add, have in no way been affected by the last authoritative pronouncement on the subject, which rejected deep underground protection against bombing as unnecessary and undesirable, as well as being economically impossible.

OCCUPANCY TESTS OF AIR-RAID SHELTERS

"To every action there is an equal and opposite reaction." Thus the provision of air raid shelters for all follows on indiscriminate bombing by aeroplane. It is with a sense of relief that we have read the report of some detailed occupancy tests of shelters for factory workers.[1] Such a research indicates the standard of our preparedness. The tests were carried out between April 19 and May 22, 1939, by Messrs. J. and E. Hall, Ltd., in collaboration with some members of the medical profession and the Department of Industrial Physiology, London School of Hygiene and Tropical Medicine.

Shelters for Factory Workers

The shelters employed are of sufficient number and capacity to accommodate the whole staff of approximately 1,700 people. Two types of shelter are adopted—one of steel, completely below ground level, and the other of pre-cast concrete, only partly below ground level. The steel shelter is a standard shelter twenty-seven feet in length with a concrete floor five inches thick. The steel is surrounded by six inches of concrete, the topmost part of which is 1 ft. 9 in. below ground level. It is entered by means of a concrete stairway, through a gas-tight door at one end, and an alternative exit is provided at the other end by means of a gas-tight trap-door reached by a step-ladder. The pre-cast concrete shelter, which is also twenty-seven feet in length, has its concrete floor approximately five feet below general ground level, and the slabs of concrete above earth level are covered with two feet of excavated earth. Both shelters have seating accommodation for fifty occupants, and they are comfortably fitted out with, among other things, electric light, wireless installation, and telephonic communication. The gross cubic capacity per person when full is 24.2 cubic feet for the steel shelter and 27.8 cubic feet for the concrete shelter.

---

[1] *Report on Occupancy Tests of Air-Raid Shelters for Factory Workers.* (Pp. 27; 3 folding diagrams. 2s. net.) London: H. K. Lewis and Co.

The tests prove that these shelters can be fully occupied for a period of two hours without ventilation and with exits and entrances sealed against gas without any serious effects on the occupants, although some discomfort and mental impairment may be apparent towards the end of this period. As it will not be necessary to close the gas-proof doors until a gas alarm is given the natural ventilation thereby permitted is enough to maintain comfortable conditions inside the shelters. Further, it is found that discomfort due to heat and moisture accumulation does not arise in a period of two hours, even though no ventilation is provided in the fully occupied shelter. The earth surrounding the shelter keeps the walls cool, and moisture condenses on their surfaces.

Concentration of Carbon Dioxide

It is observed that there is less likelihood of unpleasant concentration of carbon dioxide developing in sealed concrete shelters than in steel shelters; this may be due to the permeability and/or absorbing capacity for carbon dioxide possessed by concrete. After two hours in the sealed-up steel shelter the carbon dioxide percentage is 5.2 compared with 4.3 in the concrete shelter. If it is essential that the individuals in a fully occupied and sealed-up shelter should retain their full mental alertness it is desirable that either artificial air filtration and ventilation should be maintained or adequate oxygen should be liberated at hourly intervals and carbon dioxide continuously partially absorbed by chemicals, such as soda lime, exposed in suitable containers and locations. When no oxygen is added or carbon dioxide removed symptoms appear in all subjects at the end of the second hour, marked panting (leading to thirst, dry mouth, and throat), headache, and lassitude being prominent. At this time the carbon dioxide percentage has increased to above 5, while the oxygen percentage has fallen from the normal figure of 20.9 to that of 14.75. Such a high percentage of carbon dioxide leads to panting, headache, vertigo, nausea, and lassitude, with vomiting as a possible after-effect, while the fall in oxygen percentage is regarded as being a cause of difficulty in mind concentration. When 40 lb. of soda lime are suspended, at the end of the first hour, in forty-seven gauze bags from hooks in a line stretching from end to end of the shelter about one foot below the centre of the arch of the roof, the final figure for carbon dioxide percentage is 3.8 in place of 5.32; a hand-operated fan is used to mix the air. With this reduction of carbon dioxide concentration symptoms are almost negligible.

The condition of the occupants in these sealed-up non-ventilated shelters corresponds to some extent with that of occupants of submerged submarines. Professor J. B. S. Haldane and his colleagues[2] have recently repeated and extended experiments originally started by his father, the late J. S. Haldane, in conjunction with the late Lorrain Smith. Professor Haldane's object was to endeavour to explain the difficulties facing the occupants of the ill-fated submarine *Thetis*. Here the carbon dioxide is regarded as having exceeded 6 per cent., and the results of Professor Haldane's experiments indicate that in each of six persons who have breathed air containing this concentration of carbon dioxide with normal or subnormal oxygen for an hour there has been an aggravation of symptoms other than panting when pure air or oxygen was again breathed, and three out of six vomited as an after-effect.

It is evident that if the occupants of the air-raid shelter described in Messrs. J. and E. Hall's report remain inside much longer than two hours the carbon dioxide would rise above 6 per cent. and similar aggravation of symptoms would be expected as an after-effect. These tests certainly give some indication of the concentration of carbon dioxide permissible in such sealed-up shelters, and the limit appears to be below 5 per cent. Further, the oxygen should not be allowed to fall to 15 per cent. if mental alertness is to be maintained.

Nova et Vetera

THE DIARIES OF PETER CAMPER

Peter Camper (1722–89) seemed to have left very slight traces on the sands of time. It was known that he was interested in midwifery, that he helped Smellie with some of the plates in the *Anatomical Tables*, that he modified a pessary, was an ardent supporter of symphysiotomy, and was successively a professor in the Universities of Franeker, Amsterdam, and Groningen. The plaque made by Josiah Wedgwood preserves for us his personal appearance. The Netherlands *Opuscula Selecta* now publishes the diaries—hitherto unknown—kept by Camper on his three visits to England, the first as a lusty young Dutchman in 1748, the second in 1752, and the third in 1785, when he was a foreign Fellow of the Royal Society.[1] His first visit was made to attend the lectures of Smellie, who was revolutionizing the teaching of midwifery, and of these lectures Camper gives a detailed account, telling of the wealth of material—both living and dead—by which they were illustrated.

But Camper was much more than a man-midwife; he had ample means and first-rate introductions. These he used to the greatest advantage, and, being an encyclopaedist, young, and of a pleasant personality, he went everywhere and knew everyone worth knowing in London. Nothing came amiss to him, and he could hold his own in discussions on comparative anatomy, fossils, books, and pictures. All this he sets down in his diaries, and shows that he was outspoken without giving offence, for when he did not like a thing he said so. His diaries are full of detail, and give a striking picture of English thought and manners in the Hanoverian period: the routes he took in his various journeys, what they cost, the distance and the time they occupied—even such intimate details as "The Fountain Inn in Catherine Street on the left hand where girls can be obtained," and added in pencil, "Mis Jackson at the Tallow Chandlers, Charles Street, Covent Garden."

The diaries for the most part are written in Dutch, which, in accordance with the custom of the previous volumes issued by the Netherlands Society, have the Dutch on one page and an English translation facing it. They are edited by Dr. W. Th. Nuyens, who is to be very heartily congratulated on the completion of his task. He has not only written a full and excellent introduction, but he supplies eleven plates and drawings, adding an appendix of biographical notes on Camper's many friends and acquaintances. An index alone is wanting.

MEDICAL HISTORY OF GUY DE MAUPASSANT

In his thesis (*Thèse de Paris*, 1939, No. 324) on the psychopathology of Guy de Maupassant Dr. Guillaume Delpierre relates that this celebrated writer, who was born in 1850, died of general paralysis in 1893. He contracted syphilis between the ages of 25 and 30, but apart from severe headaches from which he suffered from the age of 26, he did not show any symptoms until 1886, when he presented inequality of the pupils, facial tremor, and dysarthria. It was not until three years later, according to Dr. Delpierre, that general paralysis had a pronounced influence on his work, but while his productive activity diminished his style still remained clear. It was only in January, 1892, or about eighteen months before his death, that after attempted suicide he became an inmate of Dr. Blanche's private asylum, to which he had taken his brother three years previously. Maupassant came of a neuropathic family, and this fact, combined with the cerebral hyperactivity, as shown by his producing twenty-seven volumes in ten years, and physical over-exertion of all kinds, contributed, along with syphilis, to the development of his psychosis.

FOREIGN PHARMACEUTICAL PRODUCTS

BRITISH EQUIVALENTS AND ALTERNATIVES

In time of war it may prove increasingly difficult to obtain supplies of pharmaceutical products of foreign origin, whether from enemy, neutral, or allied countries. The country must depend primarily on its own resources. These are far more extensive than is generally realized, while special steps have been taken during recent months to meet the possible deficiencies in an emergency. The schedule printed below has been prepared by the Association of British Chemical Manufacturers in order that the medical profession may be made fully aware of the British sources of supply for products which are available in replacement of foreign proprietaries. The information on which the correlation of foreign and British products is based in the schedule is, for the most part, generally available in other published works. While every effort has been made to ensure accuracy, the association cannot accept responsibility for the information it has obtained from these sources.

Steps have been taken to ensure that a number of essential medicinal proprietaries, hitherto imported, will be manufactured as soon as possible in the United Kingdom. Arrangements will be made, by the issue of revised editions of this schedule and otherwise, to announce these developments as they come to fruition, as well as generally to extend the scope of the information contained herein. The Association of British Chemical Manufacturers will welcome observations and suggestions from those who use this schedule, and will be glad at all times to assist in ascertaining for inquirers the British sources of supply in cases of difficulty.

At least one well-known firm of suppliers of products which we understand have hitherto been imported from abroad has announced that stocks which should satisfy normal requirements for a period are available, and that the firm has made arrangements to obtain further supplies manufactured in the U.S.A. Nevertheless it has been considered desirable to include certain of the firm's products in the list in case supplies should run short.

Note.—Bound copies of the complete schedule are available gratis on request to the Association of British Chemical Manufacturers at the address shown below.

166, Piccadilly,
London, W.1.
September, 1939.

KEY

T & H S = T. and H. Smith Ltd.
Whiffen = Whiffen and Sons Ltd.

Note.—The letter (I) following the name of a British maker and/or supplier means that the material is imported.

The British products shown can be supplied in all the forms (powder, tablet, ampoules, etc.) appropriate for each.

Column 2 gives the British product/s having the same essential composition as the item in column 1. Column 4 gives the British product/s having similar therapeutic properties and capable of replacing the product in column 1.

1 Foreign Product	2 British Product	3 British Maker and/or Supplier	4 British Product	5 British Maker and/or Supplier
Acecoline	Acetylcholine chloride	B D H B W Evans		
Acidol-pepsin	Betaine hydrochloride and pepsin	Boots (I) B D H (I) Evans (I)

			Sanusin sempules	B D H
			Enule hazeline co.	B W
Aperitol	Phenolphthalein B.P.	A & H Boots B D H Evans M & B M C Morson		
Aphrodine	Yohimbine	B D H (I) Evans (I) Johnsons (I)	Yohimbine hydrochloride	J F M (I)

1 Foreign Product	2 British Product	3 British Maker and/or Supplier	4 British Product	5 British Maker and/or Supplier
Arcanol..			Cinchophen and aspirin	Boots B D H Evans
Argyrol	Silver vitellin	Boots (I) B D H (I) Evans (I) J F M (I) M & B (I)	Collosol silver	B C
	Arvitin	Johnsons		
Aristochin			Quinine ethyl carbonate B.P.	A & H (I) Boots (I) B D H (I) B W (I) Evans (I)
Aristol ..	Thymol iodide	A & H Boots B D H Evans G. Chem Howards M & B Whiffen		
Arrhenal	Disodium methylarsenate	B D H Evans	Soamin	B W
Arsen-triferrin			Iron and arsenic ampoules and/or tablets	A & H Boots B D H B W Evans Glaxo
			Collosol iron and arsenic	B C
Aspiphenin			Aspirin and phenacetin	A & H Boots B D H B W Evans Howards
Asthmolysin			Pituitary extract and adrenaline	A & H Boots B D H Evans
Atocin..	Cinchophen B.P.	A & H Boots B D H B W Evans Howards		
Atophan..	Cinchophen B.P.	A & H Boots B D H B W Evans Howards		
Atophan balsam	Ung. agotan co.	Howards	Analgesic balm	Evans
			Analgesic cream (vanishing)	B D H
			Regesan pain relieving balm	Boots
			Menthofax	B W
Atophanyl			Cinchophen and sodium salicylate	Boots B D H Evans
Atoxyl ..	Soamin Sodium arsanilate	B W Evans M & B		
Aurobin	Crisalbine	M & B		
Bayer 250	Antrypol	B D H		
Betaxin..	Vitamin B$_1$	A & H B C B D H B W Evans Glaxo M & B		
	Berin	Glaxo		
Bioferrol			Hepol with iron	A & H
			Livron	Boots
			Crookes liver iron	B C
			Heprona. Hepatex with iron	Evans
Bismarsen			Biarsamide. Bistovol	M & B
Bismogenol	Inj. bismuth salicylate B.P.	A & H Boots B D H Evans	Bisantol	M & B

1 Foreign Product	2 British Product	3 British Maker and/or Supplier	4 British Product	5 British Maker and/or Supplier
Bismosalvan	Quinine iodobismuthate	A & H B D H Evans Whiffen		
	Quinostab Rubyl	Boots M & B		
Bitaemaine	Benzamine	Boots (I) B D H (I) B W Evans (I)		
Bivatol ..			Stabismol	Boots
			Neo-cardyl	M & B
Bromural	Dormigene	A & H (I)	Carbromal B.P.	Boots (I) B D H (I) Evans (I) M & B (I)
Cafaspin			Aspirin and caffeine	A & H Boots B D H B W Evans Howards
			Crookes antipyretic cachet	B C
Calcimint			Calcium and vitamin D	B C
			Calsolact	A & H
			Calsimil	B D H
			Salpern	Boots
			Kalsolac	Evans
			Ostocalcium	Glaxo
Calcium diuretin	Theobromine calcium salicylate	Boots Evans T & H S Whiffen	Theobromine and sodium salicylate B.P.	A & H Boots B D H Evans M & B T & H S Whiffen
Calcium (Sandoz)			Calcium gluconate B.P.	A & H Boots B D H Evans Howards Kemball M & B
			Calcium laevulinate	B C
			Percalcin	Evans
			Levu-calcin (calcium laevulinate) ampoules	Glaxo
Calsiod ..	Calcium *o*-iodoxybenzoate	Whiffen	Calcium acetylsalicylate	Boots B D H Evans Morson
	Arthrytin	M & B		
Campolon			Hepol. Anahepol. Azoule liver extract	A & H
			Hepastab. Hepastab No. 2	Boots
			Anahaemin. Liver extract (intramusc. inj.)	B D H
			Hepatex. comp. H.C.I.	Evans
			Examen	Glaxo
Cantan ..	Ascorbic acid B.P. (Vitamin C)	A & H Boots B C B D H B W Evans Glaxo	Natural vitamin C.I.	B C
	Celin	Glaxo		
	Planavit C	M & B		
Carboserin			Activated carbon	A & H Boots B D H Evans
			Charcoal and kaolin	Boots B C Evans
Cardiazol	Phrenazol	Boots	Anacardone } For use as cardiac stimulant	B D H
			Nicamide	B W
			Cardatone	Evans
			Dacorene	M & B

1 Foreign Product	2 British Product	3 British Maker and/or Supplier	4 British Product	5 British Maker and/or Supplier
Casbis ..			Inj. bismuth salicylate B.P.	A & H B D H Evans
			Metallic bismuth suspension	B C
			Stabismol	Boots
			Neo-cardyl	M & B
			Bisantol	M & B
Chinosol	Potassium hydroxyquinoline sulphate	A & H (I) Boots (I) B D H (I) Evans (I) J F M (I)		
	Soloid chinosol	B W (I)		
Chloretone	Chlorbutol B.P.	A & H Boots B D H Evans M & B Morson		
Cignolin			Chrysarobin B.P.	A & H Boots B C B D H B W Evans J F M M & B T & H S
Cito-baryum			Barium meal	Boots Glaxo
			Novumbrose. Umbrose	A & H
			Collosol barium sulphate	B C
			Shadoform	B D H
			Barolac	B W
			Fotonemal. Fotamealo. Fotamilko	Evans
Codeonal			Soluble barbitone and codeine	Boots (I) B D H (I) Evans (I)
Compral			Amidopyrine. B.P.	Boots (I) B D H (I) B W (I) Evans (I)
Coramine (Ciba)	Anacardone	B D H	Cardatone	Evans
	Nicamide	B W	Dacorene	M & B
Creosotal	Creosote carbonate	Boots (I) B D H (I) W J B Evans (I)		
Cryogenine			Phenylsemicarbazide	B D H (I) W J B Evans (I) M & B (I)
Cycloform			Benzocaine, B.P.	A & H (I) Boots (I) B D H (I) Evans (I)
Cycloform ointment			Benzocaine, extract of hamamelis, and zinc oxide ointment	B D H (I)
			Ung. hamamelis co. Evans	Evans (I)
Cylotropin			Hexamine, sodium salicylate, and caffeine	B D H Evans
Dermatol	Bismuth subgallate	A & H Boots B D H B W Evans (I) M & B Morson T & H S		
Devegan	Acetarsol vaginal compound	Evans	Silver aluminate	B C
	Stovarsol vaginal compound	M & B		
Dial ..	Allobarbitone	A & H (I) Boots (I) B D H (I) Evans (I)		
Digalen ..			Digitalin granules	A & H Boots B D H Evans
			Diginutin	B W
Digipuratum			Digitalin granules	A & H Boots B D H Evans
			Tab. digitalis leaf B.P.	A & H Boots B D H Evans
			Diginutin. Digoxin	B W
Digitaline Nativelle	Digitalin granules	A & H Boots B D H Evans	Tabloid digoxin	B W
	Digitoxin	Boots J F M (I)		
	Tabloid digitalin cryst.	B W		
Dijodyl ..			Iodoprotein	Boots
			Iodicin	B W
			Iodocasein	Whiffen
Dionin ..	Ethylmorphine hydrochloride	A & H Boots B D H B W Evans J F M M & B T & H S		
Diuretin	Theobromine and sodium salicylate B.P.	A & H Boots B D H Evans M & B T & H S Whiffen		
Duotal ..	Guaiacol carbonate	A & H B D H B W W J B Evans M & B		
Eldoform			Albumin tannate	B D H Evans M & B
Elityran ..			Thyroxine sodium B.P.	Boots B D H B W Evans
			Thyroid B.P.	A & H Boots B D H B W Evans
			Tabloid thyroxine	B W
Elixir Gabail			Elixir bromovalerianate	Boots Evans
			Euvalerol B	A & H
			Collosol bromoform co.	B C
			Elixir valibrom B.D.H.	B D H
Ephetonin*			Ephedrine hydrochloride	A & H Boots (I) B C B D H B W Evans J F M M & B T & H S
Esmodil ..			Acetylcholine	B D H Evans
			Hypoloid acetylcholine bromide	B W
			Pragmoline	M & B
Esterol ..	Benzyl succinate	A & H B D H W J B Evans		
Eugallol ..	Pyrogallol monoacetate	B D H Evans Johnsons		

* Ephetonin, a racemic mixture, is made from synthetic ephedrine, which has less therapeutic activity than the ephedrine (natural) shown as the British alternative.

1 Foreign Product	2 British Product	3 British Maker and/or Supplier	4 British Product	5 British Maker and/or Supplier
Euphthalmine	Tabloid ophthalmic euphthalmine hydrochloride	B W	Atropine sulphate B.P.	A & H Boots B D H B W Evans J F M T & H S Whiffen
			Homatropine hydrobromide	A & H Boots B D H B W Evans T & H S
			Silver with atropine	B C
Euquinine	Quinine ethyl carbonate B.P.	A & H (I) Boots (I) B D H (I) B W (I) Evans (I) Howards (I)		
Euresol ..	Resorcin monoacetate	A & H Boots B D H Evans		
Exalgin...	Methylacetanilide	A & H Boots B D H Evans		
Faexalin Faexin			Dried brewer's yeast	A & H Boots B D H Evans
Femergin			Ergotoxine ethane sulphonate B.P.	B D H B W Evans M & B
Ferronyl	Citrated ferrous chloride B.P.	A & H B D H B W Evans Howards Johnsons	Ferosan	Boots
			Fersolate	Glaxo
Fiatal ..			Female mixed glands	Boots B D H B W Evans
			Sexatones, female	Evans
Fibrolysin	Thiosinamine sodium salicylate	Boots B D H Evans	Iodolysin	A & H
			Thiosinamine ethyl iodide	Boots B D H Evans Glaxo
Fouadin			Antimony sodium tartrate B.P.	Boots B D H B W Evans M & B
			Anthiomaline	M & B
			Collosol metallic antimony	B C
Fraisse's ferruginous ampoules			Iron, arsenic, and strychnine ampoules	Boots B C B W Evans Glaxo
			F.N.S.	A & H
			Ferruginous compound ampoules	B D H
Germanin	Antrypol	B D H		
Gonosan			Sandalwood oil and kava-kava resin	B D H Evans
			Kavol	A & H
			Savaresse's santal	Evans
Gravitol			Ergotoxine ethane sulphonate B.P.	A & H Boots B D H B W Evans Glaxo
			Ergometrine B.P.	A & H B D H B W Evans M & B
			Erbolin	Glaxo
			Ernutin	B W

Reports of Societies

MALARIA IN WAR

Prophylaxis and Treatment

At a meeting of the Royal Society of Tropical Medicine and Hygiene on October 19, Sir RICKARD CHRISTOPHERS delivered his presidential address on the subject of "Malaria in War."

That there was a connexion between malaria and war, he said, was well recognized. It need not be supposed that the aetiological fundamentals were really different from those dealt with in civil life, but there were features of malaria when it occurred as a concomitant of war which were interesting and important enough to merit further consideration. In the first place, malaria in such circumstances might be much more than merely one of the causes of casualties from sickness; it might modify or even determine the results of a campaign. Again, the epidemiology of malaria in the Army in the field was likely to have features which were by no means necessarily those familiar in civil administration. Lastly, the questions of prevention and even of treatment were quite special in such a setting. Therefore there was a certain justification for the term "war malaria."

Previous War Experience

Turning to malaria in previous wars, Sir Rickard Christophers said that it was surprising that in classical writings concerning the movements of armed nations so little about the effects of malaria was to be found. Yet it was improbable, as some writers had suggested, that malaria was a relatively recent introduction in many countries. In wars since the Napoleonic era malaria did not figure very largely, except in the famous Walcheren Expedition of 1806 and the Chinese-Japanese War of 1897. In the Crimean War, 1854–6, it was not apparent, reading the *British Medical Journal* (or the *Association Medical Journal*, as it was called at that time) that there was a war on at all. In the South African War there appeared to have been only a slight amount of malaria, as also in the recent Italian-Abyssinian War.

The most important malaria experiences in the great war were those in Taranto, Macedonia, Mesopotamia, East Africa, and Palestine. Taranto came into prominence because it was realized early that troops proceeding to Egypt and other theatres of war were becoming infected even by a short stay at this port of South-East Italy. The Macedonian experience was one of the greatest medical surprises of the war, the total casualties from malaria being enormous. During the winter of 1916–17 a quarter of the whole force seemed to have been infected. In Mesopotamia the sickness from malaria was considerable, though not to be compared with the Macedonian incidence. One fact brought out was that admissions to hospital were but a small part of the actual malaria. All units in 1916–17 were supposed to be receiving prophylactic quinine, 5 grains a day; the only thing that could be said about quinine prophylaxis is that the incidence might have been heavier had it not been carried out. With regard to East Africa, the operations involved an average strength of about 50,000 troops, and the admissions for malaria in two years were estimated at 120,000. In Palestine, where in 1918 the troops suffered severely from malaria, vigorous anti-larval measures were carried out, marshes being drained, streams canalized, and wells and cisterns oiled. These and other anti-mosquito operations appeared to have reduced breeding to a minimum at a time when it might have been optimum.

Preventive Measures in the Field

The first measure of control was the constitution of a malaria inquiry laboratory. Without an adequate organization to ascertain the conditions and decide upon the steps to be taken, hopeless confusion could result. In the next place, whatever other measures might be adopted, the necessity for carrying out anti-larval operations would almost certainly arise, at all events to protect base camps and lines of communication.

With regard to quinine prophylaxis, it would be unduly optimistic in face of the experiences in the last war to regard this as a measure which could at any time be relied upon easily to control malaria in an army in the field. If anything was to be achieved in this respect far more attention must be given than at present to preparation and organization. This could be done by ensuring recognition by the higher command of the great importance of this measure, by previous propaganda among officers and men, and by detailed planning as to how the administration was most likely to be facilitated.

Mosquito-proofed huts might again be an important method of control, and the devising of suitable types of hut was worth careful consideration. The mosquito net was the method of prevention effective beyond all others in the hands of the intelligent individual, but the difficulty of utilizing it was great, and insufficient thought had been given to details, especially the means by which the net was to be supported. With electricity and modern facilities there was nothing preposterous in the idea that men might be accommodated in mosquito-proofed huts with electric fans or provided with mosquito nets under conditions in which these could be used. But all this required a good deal of thinking out and experiment before the event.

In conclusion, Sir Rickard Christophers dealt with hospital organization for blood examinations. For this purpose hospitals must have the necessary equipment—not only microscopes, but slides and stains, as well as at least one technician fully familiar with the technique of detection of parasites. He stressed the necessity for planning ahead and for having an effective advisory organization for malaria if there was any probability that large bodies of troops would again be employed in a malarious area.

Malaria in South-Eastern Europe

Dr. C. M. Wenyon said that although malaria undoubtedly figured in earlier wars, what really happened was very vague and indefinite. It was only in the last war that scientific observations were made on the method of spread and attempts at prevention were carried out to any great extent. All his own ideas on war malaria were coloured by his Macedonian experience. It was the occurrence of malaria in Macedonia which stimulated the investigations subsequently through the League of Nations over the whole of South-Eastern Europe. The experience of malaria in the last war had also assisted anti-malarial measures in the Army in India; he was sure that the methods worked out there had been highly successful, and would prove of great service should it be necessary to conduct a war again in a malarious country.

What could be done against malaria in war naturally depended on circumstances. If Gallipoli had been highly malarious it would have been impossible to carry out any considerable anti-malarial measures. Mosquito-proofed huts could not have been provided, and the only conceivable thing that could have been done, where time was of the utmost value and where the troops must not be encumbered with unnecessary material, was some form of chemoprophylaxis. On the other hand, in Macedonia, where the Army was not landed in such great haste, some sort of protection such as mosquito nets was still possible. If the occupation was slower still, as at Taranto, a great deal might be done beforehand in the way of mosquito-proofed huts.

The malarial inquiry laboratory in Macedonia, although sometimes an embarrassment to the D.A.M.S., was of considerable assistance. Such a laboratory had no place in active operations where troops were moved forward, but in static conditions, as in Macedonia, it was able to do much. It was made a rule in Macedonia that streams should be cleared and anti-malarial measures carried out over half a mile around the camps. But although a tremendous amount of clearing of streams was done on a certain plateau just outside Salonika, where there were a number of tented hospitals, the laboratory collected mosquitos regularly in the hospitals; indeed, he doubted whether the transmission rate was really reduced. It was possible that Paris green would have helped to extend anti-larval activities effectively further afield. Quinine prophylaxis seemed to do practically nothing to control the infection, but it definitely controlled the disease. When taking quinine the men did not go sick so often. Quinine, in other words, did not stop the infection, but it prevented the disease from showing itself. Nowadays atebrin might probably be used for therapeutic purposes, and quinine kept for prophylaxis. The mosquito net probably did more to prevent malaria than all the other measures in Macedonia put together. He believed that by the personal use of the net he had himself warded off at least 99 per cent. of possible bites from the anopheles.

Army Anti-malarial Organization

Major-General Marrian Perry (director and professor of pathology, Royal Army Medical College) said that he would be a brave person who hazarded a guess whether troops would be sent to a malarious station during the present war, but it might be interesting to outline briefly the organization for the laboratory diagnosis of malarial infections in the Army. At the base in an infected area there would exist fully equipped laboratories staffed by pathologists, with technicians adequately trained in diagnosis and in the identification of these infections. Further forward in the casualty clearing station area centres for laboratory diagnosis would be provided. There would be mobile laboratories serving a group of stations, and in each of the stations there would be a clinical side-room with all the necessary equipment for malaria diagnosis. In addition, within recent years there had been made available for the more advanced medical units, such as the field ambulance, easily transportable malaria-diagnosis panniers containing all the essential equipment—microscopes, stains, slides, etc. These panniers had already been in use in Palestine and on the North-West Frontier, and had been reported on satisfactorily. Malaria-diagnosis panniers would also be held in reserve at the base hospital laboratories, and could be sent forward with a detachment from those laboratories and begin work at once in any locality. Thus it would be evident that there was a plan for a chain of diagnostic centres from the forward areas to the base, and that mobile diagnostic malaria units would also be provided.

In addition to the regular R.A.M.C. officers who received a full-course of laboratory training at the R.A.M. College short-service commissioned officers liable for service abroad received a short intensive course of such training in which malaria diagnosis played a prominent part. The question of training of laboratory technicians had also not been overlooked. A large number of laboratory assistants had been enlisted and formed a pool. These were being trained in malaria diagnosis as well as in other matters. With regard to the supply of drugs other than quinine it had been ascertained that the manufacture of atebrin would be carried out in this country within the next few months. The question of the home manufacture of plasmoquine was rather more difficult but was under careful investigation. No difficulty need be anticipated with regard to stains. The Director-General of the A.M.S. was fully alive to the importance of this whole subject, and the speaker had his authority for stating that he would avail himself of the knowledge and assistance of expert malariologists should the necessity arise.

Recent Experience of Anti-malarial Measures

Colonel J. A. **Manifold** said that since the last war the Army had been continually dealing with these malaria problems, especially in India, and during the last two years in Palestine under war conditions. Therefore it was not necessary to go back to the experience of 1914–18 so far as the Army was concerned. For fifteen years to his knowledge an excellent organization had existed for the purpose. In India it was not so much to the Army authorities as to the rural councils and municipalities which controlled the civil population that warnings should be addressed. It was the infected civil population on the Army boundary which was the serious factor. It seemed to him that Sir Rickard Christophers had assumed that propaganda among the higher command was necessary, but if he knew the higher command at the present day he would realize that very little propaganda was needed. In the Jordan Valley in Palestine in 1938 the ratio of malaria was 13 per thousand. To one like himself, who had spent some years in a part of Africa where the ratio was some hundreds per thousand, it seemed that anti-malarial measures as organized in Palestine were very efficient. The same was true of Egypt, where the ratio was 3.8 per thousand, although the actual forces employed in Egypt at the time were quite large. The use of mosquito-proofed huts with electric fans had been mentioned. This was an organization which had to be faced at some stage, but until one knew where the Army was actually going and whether shipping and timber would be available, the provision of huts could hardly be demanded. A bivouac tent was tried out last year in Palestine, and he was told that it was very good. He spoke of the great value of the prophylactic dose of quinine, and also stated that anybody taking quinine in a blackwater area was very unlikely to go down with blackwater.

Colonel S. P. **James** said that in view of the careful work of the Malaria Commission of the League of Nations there were not likely to be the great medical surprises which occurred in the last war even if the present one should extend to operations in malarious country. The question arose whether it would be necessary always to carry out anti-larval operations in war time in the field. It would depend on the locality in which the operations were conducted. In many potential war areas it would be quite impossible to hope that any anti-larval operation could meet with success. In the last war almost nothing was more tragically ridiculous than the immense but quite futile efforts in the way of anti-larval operations in places where success was beyond the power of man. Of course, the difficulty was that sanitarians and others were very loath to discard such measures, but that was an administrative difficulty which in war time might be overcome. He favoured the concentration of measures applicable to the individual soldier and to the barracks, hut, or tent in which he lived rather than on indirect measures in the general environment. The daily systematic use of insecticidal sprays in barracks and outbuildings was recommended by the Malaria Commission and had given excellent results in many countries where it had been employed, and now that very efficient sprays were available he thought this was a measure for which energetic preparation ought to be made. The other two direct measures were mosquito nets and quinine prophylaxis. Every soldier ought to be provided with a mosquito net of a proper pattern and trained in its use with the same care and attention as he was doubtless trained to use his gas mask. As to quinine prophylaxis, there was no doubt about the efficacy of that measure. In war time they ought to forget that quinine did not prevent infection, and to concentrate on the fact that 5 grains of quinine a day would prevent clinical attacks.

Dr. P. **Manson-Bahr** mentioned his experience of malaria in Palestine in the last war. No planning could take place beforehand and everything had to be improvised. It fell to his lot at the end of 1917 to train officers and men in the field in the technique of diagnosing malaria. Malaria-diagnosis stations were formed, the great point about them being their extreme mobility. They were mounted on general service wagons and provided with microscopes, stains, and syringes. These followed the cavalry as far as Aleppo, and in two months 40,000 blood slides were examined, and the total number of blood examinations carried out in the last year of the war was 146,000, being practically equal to the whole force in the field. The great danger to troops in the field was the subtertian parasite, the incubation period of which was ten days.

Sir **William Willcox** added a few words about his experience of the campaign in Mesopotamia, where he worked with Sir Rickard Christophers. The curious feature was that in the mountainous regions high above sea level a more virulent form of malaria was present than in the swamps down below. He also thought it important to remember in war time that if there was an epidemic of malignant influenza it might be complicated by malaria acting in a symbiotic way.

ORGANIZATION AND TREATMENT OF AIR-RAID CASUALTIES

Dr. J. Trueta of Barcelona at Royal Society of Medicine

A meeting comprising several Sections of the Royal Society of Medicine on October 24 was addressed by Dr. J. Trueta, late director of the department of surgery, General Hospital of Catalunya, Barcelona, on the organization of hospital services for casualties due to the bombing of cities. Mr. T. P. McMurray, president of the Section of Orthopaedics, was in the chair, and the meeting was crowded, 350 being present.

Dr. Trueta said that he was glad to have the opportunity of describing his surgical experiences during the Spanish War in the hope that they might be of use to his British colleagues. The first bombardment of Barcelona was from the sea in November, 1936, when there were 100 casualties among the civil population. Air raids afterwards occurred with increasing frequency, and the hospitals altered their organization as experience demanded. For example, first-aid posts separate from hospitals were abandoned when it was found that they delayed complete treatment and resulted in an increase of mortality.

The Spanish War was the first in which what were described as "total population" tactics were employed. Barcelona and the adjacent towns and villages underwent more than 340 bombardments. The attacks were carried out for two purposes—to bomb military objectives and to terrorize the civil population. The material used in the attack differed according to the purpose in view. Against military objectives the bombs usually employed were heavy ones, weighing more than 600 lb., and the explosions produced great damage. He had seen concrete buildings nine stories in height completely destroyed by such bombs. When they fell in the street they produced cavities from ten to fifteen feet deep, with an enormous dispersion of shell fragments in an upward direction.

Another type of bomb used against buildings was the small incendiary bomb weighing only 2 or 3 lb., several hundreds of which could be carried in an aeroplane. On the buildings of Barcelona, which were chiefly of steel and concrete, the damage done by these bombs was unimportant, and their use was presently abandoned. But against buildings of lighter material, such as those at Guernica, they continued to be used. The light bombs used for terrorizing the civil population were covered with some material like aluminium, and produced thousands of splinters, many of them no larger than a finger-nail. These fragments produced great injury to the tissues, out of all proportion to the apparent damage to the skin.

Casualties in Bombarded Towns and in Front-line Warfare Contrasted

The wounds caused by the heavy bombs were very severe, and only a few cases survived. The transport of such cases was difficult, for shock and haemorrhage were increased with movement. Dispatch to the nearest hospital for complete treatment was the only measure which could save life. Those injured in the collapse of buildings as the result of explosions also needed immediate assistance, and even when such assistance was forthcoming mortality was very high. Cases should be treated in the hospital within two hours of the injury. There was a difference in this respect between casualties in a bombarded town and those occurring in front-line warfare. The latter were due to rifle and machine-gun bullets and to shells, which, if not very near, were not so destructive as aerial bombs. The changing position of the front line in trench warfare required the establishment of hospitals at a sufficient distance behind the lines, out of reach of heavy artillery, and in the front line the collection of casualties was continued systematically. In the open, bombarded town, on the other hand, the gravity of the casualties, the proximity of the hospitals, the fact that many victims were injured simultaneously and included women and children, and the absence of rigid discipline made a different organization necessary.

The methods of dealing with the injured in a bombarded town had more in common with those used in towns besieged by armies than with those employed in front-line fighting, though many surgeons who had experience of a besieged town would say that there was always in such conditions the possibility of transporting the victims to safe hospitals, whereas in a city subject to air attack there was no safe place at all. This, however, was only relatively true, as experience in Barcelona had shown. In the city itself there were five hospitals, not one of which was ever hit in the bombardments, but hospitals in the surrounding country, outside the defended area, were bombed several times and put out of action. In one raid alone, when such a hospital suffered, eighty-three were killed and 118 wounded. The reason for this difference was that when attacking planes were flying over defended territory they had to fly at great altitudes, with consequent lack of precision. For example, the electric power station in Barcelona was repeatedly attacked but only once slightly damaged, whereas a factory in a village forty miles away was attacked four times and entirely destroyed.

Getting Casualties to Hospital

Dr. Trueta strongly urged that first-aid posts should be located in the hospitals of the towns subject to bombardment. More than 30 per cent. of the patients needed operation, and whatever facilitated rapid admission to hospital contributed to the more favourable outcome of the treatment. He gave a picture of the pressure on the casualty service during a three days' bombardment of Barcelona in March, 1938, when sixty doctors at the hospital worked almost uninterruptedly for the whole seventy-two hours, and the surgical units were completely exhausted after carrying out 731 operations.

Speed of transport was the first essential. He operated on one victim who had been transported five miles in eighteen minutes; generally about twenty or thirty minutes were taken to cover such a distance. The immediate intervention of the surgeon at the hospital was the only useful form of first aid other than the application of the tourniquet to a limb if there was excessive bleeding. The application of splints, bandages, and other forms of first aid at isolated posts was not only useless but actually dangerous, because it delayed surgical treatment. Such first-aid posts as were organized in Barcelona during the early days of the war were useful only for the treatment of slightly wounded cases and for reassuring the nervous, and the first-aid post in the hospital itself could equally be used for the treatment of the slightly wounded, but only after they had passed through the classification room.

A perfect circulation of ambulances was necessary. A great difference of efficiency was noticed as between two hospitals in Barcelona, one of which had made no provision for the circulation of ambulances, so that much confusion and delay ensued, while the other, having large gardens in its vicinity, was able to impose a system of one-way traffic.

A crucial point was perfect co-operation between the services, especially between the centre for the classification of the wounded and the various operating theatres and wards of the hospital. The casualties should be classified into five groups:

1. People who required immediate operation and whom it was impossible to send out of hospital immediately after treatment.
2. Those who required immediate operation and could be evacuated afterwards.
3. Those who needed immediate treatment and rest without operation and could not be evacuated.
4. Those who after receiving first-aid could be transferred to the base hospital for future treatment.
5. Those who could go home after first-aid treatment.

In the classification room an appropriately coloured card should be attached to each injured person. The director of the classification unit should know the number of surgeons and operating tables available and the specialty of each surgeon, so that the cases might be distributed according to capacity and with some regard to the pressure on each operator. In the surgical units in Barcelona general practitioners and specialists were included, the specialists including an ophthalmologist on account of the frequency of eye injuries. A twenty-four-hour service was established with six units, each made up of eight doctors. Each of the units in turn remained in hospital for twenty-four hours consecutively, and the others were at call.

Clinical Features of Air-raid Injuries

The clinical features of the injuries (Dr. Trueta continued) varied according to the nature of the bombardment, though it was very common to have different types of bombs used in the same raid, and in most raids casualties were also produced by falling masonry. In undefended areas people were frequently wounded by bullets fired from low-flying planes. Generally speaking, those wounded in the streets were less seriously injured than those in fallen buildings. In many raids there were people so gravely wounded with multiple fractures, internal haemorrhage, and gross injuries of chest and abdominal viscera that no surgical treatment was of any help. A feature common to all the injured, especially those injured by fallen buildings, was a marked fall of blood pressure, with a waxy pallor of the skin; they were in a state of mental excitement, but mental depression was rare except in those so gravely wounded that all treatment was hopeless. It was very impressive to see a great collection of wounded directly after an air attack. They were extremely quiet, and there was little crying or moaning in spite of grave wounds, in marked contrast to the excitement and noise of their uninjured friends and relatives.

The types of injuries produced by the bombs could be classed into those produced by heavy bombs and those by light ones. Wounds produced by big shells coming from heavy bombs which fell in the streets but which were aimed against buildings were very destructive, having the character of wounds produced by artillery fire. The following table represented an attempted grouping of wounds; many of these patients, of course, had minor injuries in other parts of the body:

Multiple major injuries	32.6 per cent:
Lower limbs (including hips)	22.3 „ „
Upper limbs (including shoulders)	14.7 „ „
Thorax	12.1 „ „
Abdomen	9.1 „ „
Head (skull and face)	8.2 „ „

In speaking of surgical technique, Dr, Trueta said that he had several times seen infective complications due to insufficient operative exposure. Many of the patients wounded in the abdomen by heavy bombs entered the hospital with great lacerations which made impossible all attempts at intestinal reconstruction. He could recall only two such cases which survived. In the thorax the heavy bomb injuries caused open chest wounds, which were always extremely grave owing to haemorrhage and shock. It was necessary in many cases to practise pneumonectomy. When the first danger was over it was common to see infective complications in the pleura and pleural adhesions, and in several cases he had seen paraplegia following fracture of the spinal column associated with chest injuries. Patients severely wounded in the head by these large bombs rarely arrived alive at hospital, but he had had cases in which the only surgical treatment called for was excision of the edges of the wound, removal of the damaged tissue, and aseptic dressing. Meningo-encephalitis was the most frequent cause of death after these head injuries.

Injuries by Small Bomb Splinters

The small bombs used on Barcelona to terrorize the civil population gave wounds whose appearance differed completely from those inflicted by the heavy bombs. The bombs had great expansive power. A large number of little splinters from them entered the skin—especially the skin of the legs, because the splinters had a horizontal projection—and the skin lesion was painless and without haemorrhage, so that the fact of injury was overlooked in many cases. There was great disproportion between the size of the splinter and the damage done to fascia and muscle; this was to be attributed to the spin which the splinter possessed. Severe comminuted fractures were frequently seen, with great displacements, caused by a very small splinter. It was necessary to operate on all fractures produced by these small splinters, notwithstanding that the minor importance of the skin lesion might lead one to treat them as if they were closed. That mistake had led to several deaths from septicaemia, and especially gas gangrene.

Wounds of the abdomen were generally penetrating and laparotomy was necessary. Rupture of the liver as the result of a small splinter injury was not uncommon, nor was injury of the spleen, which made removal necessary. In the chest these splinters produced very small penetrating wounds, frequently causing severe haemorrhage. It was only the cases with such haemorrhage which needed immediate operation. Generally immobilization of the chest, with rest and morphine, was sufficient, though later operation might be necessary on account of some complication. In the brain the splinter might lie deeply, and owing to the fact that many civilians lay on the floor during an air raid splinters were frequently localized in the base of the skull.

As for casualties produced by falling masonry, the injuries in this group were of all kinds, but there were some common characteristics. The patients generally arrived at hospital covered with dust, making them unrecognizable; they were in a state of shock usually combined with some concussion, and they expressed their feelings with clearness but with indifference. Many of them had numerous injuries, fractures, haemorrhage, rupture of the liver, kidney, or spleen, and showed general collapse. It was not often possible to operate on these casualties immediately because surgical intervention increased the shock, but fortunately in many cases, when shock diminished with appropriate treatment, it was possible to perform an operation.

Classification of Cases

Following upon an air raid, all the injured people arrived at hospital within a very short time and classification was the first procedure. It was possible to send many casualties to base hospitals, but a rigid classification could not be made, for the patient was more important than the lesion, and similar lesions resulted in cases of very different degrees of gravity. Generally speaking, injuries which needed immediate operation included cases in which there was severe haemorrhage, open chest wounds, and injuries involving great destruction and laceration. Other injuries which in most cases needed immediate operation were major wounds of the head, combined fractures, and penetrating wounds in the joints. Injuries which could be sent to the base hospital without operation included penetrating wounds of the skull caused by small splinter bombs, many combined fractures from small splinters, and injuries from falling masonry. Casualties which must remain in the clearing station without operation included those with great shock and those with closed penetrating wounds in the chest. With these criteria it was possible to make a careful selection, but a classification must be made from clinical data in each case. He added that operations should be carried out only on those cases which it was possible to save. Instead of losing time over hopeless cases all energies should be concentrated on those with a better chance of recovery.

Questions and Discussion

In reply to a questioner who asked his opinion of the mobile first-aid units, several of which had been commissioned in one London borough, Dr. Trueta said that in Barcelona during the first year of the civil war an organization of that kind was arranged, with five mobile units, but later they were abandoned and every kind of transport was commandeered for taking all patients direct to hospital. The hospitals in every district carried out first aid, classification, operative work, and evacuation to base. In reply to another question he said that an abundant supply of plaster-of-Paris was ensured in Barcelona, gypsum being a Catalonian product.

Professor J. Duncan White inquired what proportion of the surgically injured required immediate *x*-ray examination before surgical intervention. It was a frequent instruction that every case in which bone injury was suspected should be *x*-rayed, but this would mean a tremendous organization in air-raid casualty work. Dr. Trueta replied that in Barcelona after every important bombardment it was impossible, with very few exceptions, to *x*-ray cases before treating them.

Professor G. R. Girdlestone said that in a previous conversation with Dr. Trueta he had gathered in rather more detail than Dr. Trueta had had opportunity to give on that occasion what happened when the patients got to hospital. They were all taken into one biggish room staffed by second-grade—that is, less experienced—medical personnel. Here a preliminary classification was made, and the casualties were drafted rapidly to the first-aid post, which was also in the hospital. The work at the first-aid post came after the large preliminary examination. Other cases went on to a second classification room, where the patients were completely undressed and inspected by medical personnel of great experience. Here the cases were graded in order of priority—those which needed immediate operation, those which could be sent to the base hospital without operation, and those which must remain without operation at the clearing station—according to the scheme which Dr. Trueta had described; but it was necessary, as he had said, to bear in mind that the individual patient was more important than any standard classification. It was the surgeons who decided what must be done, and the classifying surgeon directed the patients to the different surgical teams, not only in accordance with priority and need for operation, but also having in view which surgeons would be best able to deal with the particular type of injury. This second classification required judgment of a very high order, and as a result of it the patients were drafted to the theatre, the resuscitation room, or the wards, as the case might be.

Mr. Rowley Bristow, in moving a vote of thanks, said that it looked as if a very careful reconsideration of some of the arrangements in this country might well be made following on the lines of the address which Dr. Trueta had given, and the sooner his address was published, read, and digested the better for those who controlled their destinies and the destinies of their hospitals.

Local News

ENGLAND AND WALES

Mental Health of Children

The Child Guidance Council reports that of forty-three recognized child guidance clinics in England and Wales, twenty-five are still open. This number represents all clinics except those in London and Southampton, and they as usual undertake the treatment of nervous, difficult, delinquent, and retarded children. Some of these clinics are situated in receiving areas, and so are available for the treatment of the more seriously disturbed evacuees. Addresses of these clinics and particulars of sessions, etc., may be obtained from the Council's new offices at 23, Queen Square, Bath (telephone: Bath 2390). It is hoped that some of the London clinics may reopen shortly. The Tavistock Clinic Children's Department has been removed to Westfield College, Kidderpore Avenue, N.W.3, and is open, but unable at present to receive non-paying patients. The West End Hospital for Nervous Diseases children's department is closed, but juvenile cases can be seen in the general psychotherapy department. It is hoped that the clinics attached to St. Thomas's Hospital and the Queen's Hospital may reopen shortly. Urgent cases can be seen at the child guidance unit at Great Ormond Street Hospital for Sick Children. The Maudsley Hospital is closed and removed to Mill Hill Emergency Hospital, but work for children is being carried out at the following London County Council "North" London Clinics: St. Mary's Hospital, Highgate; St. Charles's Hospital, Ladbroke Grove; Mile End Hospital, Bancroft Road, E.1. Cases can be seen at these hospitals by appointment only.

Arrangements under Cancer Act

The Minister of Health, in a circular (No. 1884) to county and county borough councils, states that he has decided to extend until March 31, 1941, the period in which they have to submit their arrangements under the Cancer Act, 1939, for his approval. The Act provides that the arrangements must be submitted within one year from its commencement—that is, by March 29, 1940—or such longer period as the Minister may in any case allow. The Minister states that he realizes that by reason of the heavy pressure of extra work in recent months it has not been possible for local authorities generally to give such attention to the matter as would enable them to submit their arrangements within the statutory period, and he has therefore granted a general extension of just over twelve months.

The National Central Library in Time of War

In times of peace the British Isles has, in addition to a splendid public library service, a system of library co-operation (in which the British Medical Association takes part) whereby all persons requiring books for any serious purpose are able to obtain them through their local public, university, or other library. The country is divided into a series of regional library systems; each system covering a group of neighbouring counties, and each having a regional bureau at which a union catalogue of the non-fiction books in nearly all the libraries in the area has been, or is being, compiled. The keystone of the national system is the National Central Library, which, in addition to being itself a great lending library, is the national centre for the inter-lending of books between one library and another. The system has become so efficient that practically any kind of serious literature can now be obtained on loan. The service is available to every branch of the community, from persons requiring information on the humblest everyday matters to research workers needing highly specialized and technical literature. In time of war the national library service will not only continue to be of the utmost importance to those who need books for general purposes, but it will also be of greatly increased value to Government Departments, organizations, and persons needing special literature in connexion with work of national importance. The National Central Library will naturally give priority to the latter service, as it is recognized that in tracing material for persons doing research on all forms of armaments, chemicals, foodstuffs, medicine, and so on, the Library will be filling a gap the existence of which was so serious a drawback during the last war. The organization of the National Central Library, with its great union catalogues and other unique bibliographical material, and the access it has to over twenty-one million books in other libraries in the British Isles, places it in an exceptional position to give service in time of war. Owing to the risk of the destruction of property at the headquarters of the National Central Library in London, all the union catalogues, as well as all other irreplaceable or scarce bibliographical material, have been removed to Bourne Lodge, Bourne End, Hemel Hempstead, Herts. The non-bibliographical books are remaining at the London headquarters in Malet Place, W.C.1.

Correspondence

Doctor and Patient in War Time

Sir,—As a surgeon my only reason for taking part in this correspondence is that the neuroses in war time are less likely to be solely the concern of the physician than they often are in times of peace. The war casualty is in fact more likely to have wounds of the spirit in addition to those of the flesh than is his peace-time counterpart. Should war actually involve the civilian population of this country then this combination of injuries will certainly increase rapidly. Already war neuroses can be detected in patients attending surgical (and other) out-patient departments. Some of the arguments put forward by Dr. Geoffrey Evans in his letter in the *Journal* of October 7 (p. 742) strike me as being so fallacious as to call for comment, and also by implication to imperil the fundamental relationship between patient and doctor. Under war conditions a free choice of doctor is no longer possible, either in the Emergency Medical Service or in the Services, and this fact is an additional argument for maintaining an important relationship unimpaired.

Dr. Geoffrey Evans says in connexion with the doctor's attitude to his patients that "we must sedulously refuse every thought of fear, regret, resentment, and the like, because these thoughts arouse emotions that have a weakening effect." Is this thorough-going self-purgation possible, biological, or wise? Reason may overcome fear, etc., but I doubt if this complete suppression of emotions can be carried out without our becoming medical automata towards our patients. Slogans have a habit of coming home to roost. On all sides we are told, "Your courage, Your cheerfulness, Your resolution, will bring us victory." This may be true, but it leaves unanswered the question whether the victory is to be of force, of reason, or of the spirit. At the present time I am (with hundreds of my colleagues) haunted by the fear of my inability to pay my rent, rates, taxes, etc.; I am filled with regret at many of the actions of the Ministry of Health; and I burn with resentment at the treatment meted out to some of my friends in the present emergency, treatment which would hardly be justified even under a dictatorship. But I do not as yet feel weakened by the emotions which have been aroused, and as far as I am aware neither my relationship to my patients, nor my patients themselves, nor my surgical ability, has been adversely affected. Whether I can control these emotions for the three years envisaged by the Government remains to be seen.

I cannot believe either that it is necessary or advisable to purge ourselves so thoroughly in order to help war-worn patients. The best that we give our patients is usually given unconsciously, and I doubt if we shall improve matters by a course of auto-suggestion. I know I shall not be a good doctor unless I can keep a credit balance from which to give the patient the help he needs. And I shall feel far stronger in this respect if I have not attempted to dispose of my emotions by repression.

What is this "good stuff" which Dr. Geoffrey Evans advises us to collect to give our patients? Is it a totalitarian attitude of mind, is it a sort of psychological salesmanship, or is it almost propaganda? The "good stuff" hardly seems to be "the stuff to give the troops," whether military or civil.

What of these colourless questions? No intelligent doctor should allow his feelings strongly to colour his words or questions, but need the questions be as colourless as Dr. Evans implies? Such questions will suggest no real interest, and they will be as featureless and flat as the phrases of a French exercise book. Self-purged medical purists will sterilize the fundamental human relationship between patient and doctor, and the patient at least will not be helped. Reactions may tend to be more exaggerated and more primitive in war, but I cannot believe that our response to these phenomena should be an exaggerated impersonal attitude.

Confidence is the basis of the relationship between patient and doctor, and this alone will enable the patient to express himself freely. This confidence will not be helped by too impersonal an attitude on our part or by the use of language purified of all emotional content. The patient comes to us just because he has a *complaint* and because he knows that up to a point we shall be *sorry* for him. The relationship, being one of real dependence, is one which necessarily holds some emotional content. Unless we have some capacity to be sorry for our patients and to indicate that our interest is not merely academic, we shall certainly not be good individual doctors. Surely in dealing with neuroses the doctor will do best who remains an individual understanding being, and not one who has (or apparently has) purged his being of emotional possibilities.

Certainly we should choose our words wisely and weigh them carefully. But it is not necessary to go to the realms of colourlessness to avoid distressing our patients, and by so doing we may embarrass them.—I am, etc.,

St. Mary's Hospital, London, W.2, Oct. 12. REGINALD T. PAYNE.

Psychiatric Casualties of War

SIR,—I read with interest Dr. George Pegge's article on psychiatric casualties of the first days of war (*Journal*, October 14, p. 764). I cannot, however, entirely agree with his conclusion that "cases in which neurosis was established before the outbreak of war are, so far, in many instances, quite unaffected by war strain."

Among my out-patients at the Tower House Psychotherapeutic Clinic, Leicester, the effect of the stress during the first days of war seemed to divide them into three categories.

1. Those who, like Dr. Pegge's cases, were not appreciably affected by the war. These, however, were in the minority, and were the more chronic neurotics who were not responding well to treatment or who showed mild psychotic features. Delinquency and child-guidance cases also were unaffected.

2. Those who improved considerably and unexpectedly. The extra calls upon them seemed to inspire a new purpose in living. They became busy in "blacking-out," etc., and have taken on some voluntary work of national importance, and in fresh activity have become free from symptoms. It is, of course, too soon to say whether they will be able to keep well.

3. Those whose treatment was progressing satisfactorily but have shown a marked relapse which, apart from the outbreak of war, would have been unlikely. These were mainly anxiety states. Some have shown an acute anxiety reaction, with exaggerated fears of danger. They are quite unamenable to reassurances, and patriotic posters such as "Your Courage, Your Cheerfulness, Your Resolution . . .," etc., are almost sufficient to precipitate an anxiety attack whenever seen. These are just the qualities they have lost. Their treatment has been so far by no means easy. In fact their superficial war anxieties seem to form a definite bar, or defence reaction, against the deeper psychotherapeutic treatment which previously was satisfactory. In others there has been an extreme irritability with an aggressive reaction towards their relatives. These are responding well and are able to continue the improvement previously being made. There must be many patients of this third group, responding well to various forms of general or specialized psychological treatment, who whenever danger threatens are likely to add to the difficulties of practitioners and first-aid posts.—I am, etc.,

W. H. WHILES, M.R.C.S., L.R.C.P., D.P.M.
Leicester, Oct. 18.

Chemical Warfare and the Doctor

SIR,—In his valuable article on this subject in your issue of October 14 (p. 778) Colonel E. M. Cowell advises the head-down tilt in cases of pulmonary oedema after phosgene gas. Also he says, "Treat all such lung casualties as stretcher cases, and after admission keep them quiet in bed." Both these recommendations can be carried out by a cheap and simple tilting bed which I have recently introduced (made by Siddall and Hilton, Sowerby Bridge, Yorkshire). For this bed can be tilted and clamped at any angle—head-up or head-down—and I am told it should be useful for draining gas casualties, besides its many other medical and surgical uses.[1]

Colonel Cowell proceeds: "For both HCN and H_2S prolonged artificial respiration with administration of O_2 and CO_2 is indicated. In these cases some form of artificial respiration by apparatus, such as an 'iron lung,' Eve-Riley rocking stretcher, or the Tor tilter, may save life." May I add that the above tilting bed is also able to produce artificial respiration by my 1932 rocking method (a dozen rocks a minute). A rockable bed has the advantages of warmth and comfort for hospital cases, and it can also be used as a flat hospital bed.

Colonel Cowell also—for phosgene cases—advises that nurses should be instructed how to give oxygen (average 5 litres per minute) with tents or masks. This year I have designed for nurses a simple "ward flowmeter" with a large bobbin weighted by a chain. This cannot be knocked over, and the nurse can read it from the other side of the ward. It is strongly made by Coxeter and Son, Morden Road Factory, London, S.W.19.

Here, then, are three more ways in which these gas cases may be helped.—I am, etc.,

Hull, Oct. 14. FRANK C. EVE, M.D., F.R.C.P.

Eye Ointment for Gas Poisoning

SIR,—In view of the possibility of the Germans using gas it is necessary that every R.A.M.C. officer should know what to do with regard to eye burns. During the last war the great majority of such cases were not treated until the soldiers had got beyond the casualty clearing stations. Mere lavage is not sufficient. Lavage with an alkaline lotion such as sodium bicarbonate 5 grains to the ounce, or indeed simple saline, helps to clear the conjunctival sac, but may I suggest that the following ointment be at once instilled for the first twenty-four hours:

Tube A. ℞ Sod. bicarb. .. .. .. 3 per cent.
Aqua dest. } āā 10 per cent.
Adip. lan. anhydr. }
Paraffin molle alb. .. ad 100 per cent.
Ft. ung. Tube.
Sig. Alkaline eye salve for gas poisoning.
First twenty-four hours.

The second twenty-four hours the following:

Tube B. ℞ Ung. ac. boracis .. .. 10 per cent.
Sig. Ophthalmic ointment. Tube.
Second twenty-four hours.

Indeed, Tube B can be continued indefinitely. These tubes are made up by Messrs. Allen and Hanburys according to my instructions.

The patient pulls the lower lid down, lays a worm-like piece of the ointment along the lower fornix, then looks down and closes his eye. Thus the upper lid imprisons the ointment.

---

[1] *Lancet*, March 11, 1939.

This method is much simpler than the use of a glass rod, and the ointment is not squeezed out between the lids. The eyes should be kept bandaged.

I give this prescription to all soldiers and officers wherever possible, and I would strongly recommend all medical men to do the same.—I am, etc.,

London, W.1, Oct. 19. R. Lindsay Rea.

Work of the L.C.C.

Sir,—I should like to thank you for the references you made in your issue of October 14 (p. 775) to the work of our retiring and much esteemed medical officer of health, Sir Frederick Menzies. Anyone who listened to the debate in the London County Council on October 17 must have realized that everything which you said about his work for London was fully confirmed by those who have been in the closest contact with him.

I must, however, draw attention to certain words—not about Sir Frederick—in your article which I am sure will give rise to a false impression. You refer to "the virtual disappearance for the duration of the war of the L.C.C. public health department and the hospital services as a unit organization." Surely a public health department is just as important, if not more so, in time of war as in that of peace. It would be a sad commentary on our much-vaunted public health work if, at a time when the life of the community is at stake, we relaxed our efforts, in the smallest degree, to preserve the health of every man, woman, and child. With regard to the hospital service, it is true that the Minister of Health directs what use shall be made of hospitals, but the Minister has placed upon the Council the responsibility for the administration and management of all the L.C.C. hospitals (Circular 1874). Further, one has only to mention the Council's responsibility for the civilian sick, the maternity service, the treatment of venereal diseases and tuberculosis, and for general public health to realize the extent of the work still being done at County Hall.

The impression, therefore, that the public health department has virtually disappeared is inaccurate.—I am, etc.,

Somerville Hastings.
Chairman of the Hospitals and Medical Services Committee.

The County Hall, London, S.E.1,
Oct. 17.

Hospital Posts and the E.M.S.

Sir,—Professor L. J. Witts's letter in your issue of October 21 (p. 825) illustrates the widespread confusion which exists as to the intentions of the Ministry of Health regarding the junior officers of the Emergency Medical Service. His statement that "most of our hospital appointments have been indefinitely prolonged by the outbreak of war" is presumably based on the "contacts" guaranteeing a minimum of one year's service which were sent on August 31 to housemen then holding appointments at many of the London and provincial hospitals. Although no official statement to this effect has been made, I understand that these "contracts" (which are not, in fact, legally binding documents) were sent out in error, the original intention having been to offer only three months' guaranteed service. Since then the Ministry has made two attempts to amend its mistake. The first, an invitation on the part of Group Officers to the housemen concerned to resign their "contracts" on the date on which their original appointment would have terminated, has apparently been applied to only a few of the London sectors. The second, a clumsy attempt to cancel the "contracts" altogether, was repudiated semi-officially almost as soon as it was made. No further official announcement has been made, but it appears likely that the Ministry does not intend to allow present housemen to hold their appointments beyond the original term and that from then onwards appointments will be made for three or six months only, at a salary of £200 per annum plus maintenance. Since it is also likely that candidates for the Services will not be accepted unless they have held a hospital appointment, Professor Witts's ideal of compulsory hospital appointments seems likely to obtain some degree of realization.

There is, however, another aspect of the organization which seems to have received less attention than it deserves. In normal circumstances a selected minority of housemen, at the end of their term of office, go on to obtain higher qualifications and, to take up more responsible hospital appointments, as registrars, R.S.O.s, R.M.O.s, etc., in order to fit themselves for more specialized work as surgeons, consultants, and so on. Of such appointments Professor Witts's complaint that "the normal turnover . . . has ceased" is true, for their holders at the outbreak of war have almost all received long-term contracts which the Ministry of Health does not appear to wish to repudiate. It seems to be assumed that all present and future housemen, for the duration of the war, will join the Services the moment their house appointments are ended. This is particularly hard on some of the present housemen who, after a thorough peace-time training, have been working for perhaps two years or more since qualification with a view to taking the F.R.C.S. or the M.R.C.P. or some other advanced degree in the next few months, and obtaining the additional experience which a more responsible or more specialized hospital appointment can afford. They are now faced, at the end of their present appointment, with the alternatives of remaining unemployed while they attempt to get the higher qualifications without additional experience or of immediately joining the Services, where their opportunities for completing their postgraduate training will be, to say the least, limited. If the demand for newly qualified medical personnel by the Services develops as expected, their war-time successors will have no choice.

But surely there will also be a demand by the Services for more experienced men—for surgical and medical specialists of all sorts—which will have to be satisfied. There may be a few of the present junior officers in the Services who will be lucky enough to get the chance to fit themselves during the next few months to fill such posts. But the difficulties and varied requirements of military medical organization are such that not only will there be no assurance that these officers are the most suitable for such training but also that the demand will exceed the supply from this source and will have to be satisfied, in part at least, at the expense of the civilian medical services. These services themselves, as they expand owing to the increasing influx of civilian and, perhaps, military casualties, are likely to need more specialists for their own purposes, quite apart from the gaps made by military demands, deaths, and retirements. There will thus be an urgent need for men with more experience and qualification than can be got in thirty months' clinical study and six months' house appointment.

Under the emergency organization of the E.M.S., set up so hurriedly at the beginning of September, some of the more senior housemen are already, in fact if not in name, doing the work of registrars and chief assistants, while senior students are doing the work of housemen. It should therefore be possible to find room in the E.M.S. for an intermediate grade of medical officer, to which the more promising housemen can be promoted at the end of their six-months appointment, so as to give them more responsible work, still under some supervision, and the opportunity for higher study and qualification before they go to the Services or, if needed, to higher posts in the E.M.S. This need not reduce the number of house appointments available for the newly qualified, and it will help to ensure that the standard of British medicine is not lowered for the future by a failure to give young talent the opportunity to fulfil its promise.

For personal reasons which will be readily understood I subscribe myself

London, Oct. 22. Houseman.

Medical Education in War

Sir,—The question of medical education in its relation to the Emergency Medical Service is being discussed in the medical journals by teachers, students, and editors, and, in the case of the last, reference has on more than one occasion been made to the "twelve teaching hospitals" in London.

It is natural that the thirteenth school should be a little jealous of its position, and I hope that such references will not lead your readers to infer that the West London Hospital Medical School has ceased to exist. On the contrary, it is, I believe, the only medical school in London where all the students are still working in their own hospital. Twenty-two women and six men are still following a curriculum which is as complete as it can be in view of the scattering of the teaching staff in Sector VII of the E.M.S. and the reservation of many beds for air-raid casualties. The general and special branches of medicine and surgery (including public health and obstetrics) are all still being taught, and the reduction of clinical material is to some extent offset by the more rapid turnover resulting from the early evacuation of cases.

Our most serious problem is pathology. Our pathologists and technicians have left us, and we have had to make temporary arrangements elsewhere for the teaching of this subject to the new students who have entered this term. Other schools, I hear, are making efforts to improvise pathological teaching in hopelessly unsuitable premises. Under such conditions practical work in the ordinary sense will be impossible and its omission will be a serious loss to the curriculum. At the West London we are hoping that it may be possible to resume teaching in our own well-equipped laboratories and class-rooms in the New Year. But this cannot be done without the help of both the pathologists and the technicians who have been called up in the Emergency Medical Service.

The organization of the E.M.S. appears to have been conceived and executed without any thought for the needs of medical education. This may have been unavoidable, as those responsible were doubtless advised that nothing would be left of London but smoking ruins after a few weeks of war. It is no use criticizing the authorities for what has happened in the past, however much each one of us may feel that he could have done it better himself. But for the future it is very much to be hoped that the Minister of Health will realize the urgency of continuing medical education with as little lowering of the usual standards as possible. To ensure this it will be necessary to make available the pathological teachers and technicians who are at present working in the sectors under conditions which make teaching difficult, if not impossible. Unless and until air hostilities prevent it, it would surely be wise, wherever possible, for pathological teaching to be carried out in the usual class-rooms, rather than in the badly equipped accommodation, such as can only be provided by the public assistance and other hospitals which are now being used for potential casualties.—I am, etc.,

MAURICE SHAW,
Dean,
Oct. 23. West London Hospital Medical School.

SIR,—May we draw the attention of your readers to a matter which we feel must be of great concern to members of the medical profession, and which is of immediate importance to us as medical students?

The Emergency Medical Scheme came into force six weeks ago, and since then there has been a widespread dislocation in the teaching arrangements of all the London medical schools; at the time of writing there is no indication of when teaching will be resumed. Under the present system, students in their clinical years are distributed among the casualty clearing stations in their respective sectors, where they are attached to blood transfusion and surgical teams. In some hospitals the staff have voluntarily instituted teaching, which, while often of a high standard, is not officially recognized. In others there is none, and in few is there adequate clinical material. Under war conditions, when the need for doctors is certain to become greater, we cannot view this lack of organized teaching with anything but dismay, and we are earnestly hoping that some plan for organized medical education will very soon appear. Anticipating such a plan, we venture to suggest the following proposals:

1. *Pre-clinical Training.*—All efforts should be made to ensure that the numbers of students entering on training should not be reduced.

2. *Teaching.*—That the standard of education should suffer as little as possible. Teaching centres should be set up throughout each sector to be attended by all students in neighbouring casualty clearing stations, and vital clinical appointments should be ensured by rotation of students to hospitals where there is appropriate clinical material. While each student should have his emergency station in the E.M.S., the short periods during which his education is interrupted should not count as part of his course.

3. *Economic Conditions.*—Steps should be taken to see that students should not be compelled to give up their careers because of economic hardships imposed by war conditions. Hardship committees to deal with such cases might be set up, including responsible student representatives with first-hand knowledge of students' difficulties.

4. *Examinations.*—The standard of examinations should not be lowered. If it is temporarily necessary to qualify men in a shorter time than normal, this should be achieved by a shorter and more intense period of training, rather than by merely curtailing the present clinical course and making the examination easier to pass. We consider that under the present circumstances the organization of medical training could be more effectively carried out by some central body, such as the University of London, as opposed to the isolated efforts of individual medical schools. In this case the resources of all the London and surrounding hospitals could be pooled and made available for all.

While we fully appreciate the magnitude of the task of reorganizing medical teaching, and the great efforts that are being made by those responsible for it, it is in the interest of both the general public and the medical profession that this should be accomplished as rapidly as possible. We hope that the few suggestions we have made will be of assistance in meeting this urgent situation.—We are, etc.,

A GROUP OF LONDON MEDICAL STUDENTS.
28, Great Percy Street, W.C.1, October 16.

X-ray Examination of Militiamen

SIR,—With reference to the correspondence about the *x*-ray examination of militiamen, the best and cheapest method is, I consider, the one introduced in the U.S.A. by Powers *X*-ray Products Inc., which I had the opportunity of seeing over there. This is well-established and recognized by tuberculosis officers and leading chest physicians in the States.

By this method one *x*-ray machine can take films of up to 1,000 men a day (two to three per minute). The personnel required is one radiologist, two radiographers, and a secretary. The films used are paper films in rolls of fifty or a hundred exposures. A viewing box with direct instead of transmitted light is needed. According to American authorities the cost of examinations is thus reduced by about 50 per cent.

The importance of the *x*-ray examination of all H.M. Forces must be emphasized. First, it would reduce the number of pensions payable by the early detection of cases of tuberculosis; and, secondly, the spread of the infection to healthy people would be avoided.—I am, etc.,

London, N.6, Oct. 9. LEO RAU.

Problems of Evacuation

SIR,—We hear a great deal of the difficulties arising from the evacuation of children, and the time now seems ripe for spreading knowledge of those measures which can be taken to deal with such difficulties, and which are already being so successfully practised in Huntingdonshire.

Here, where some hundreds of children have been billeted, at least seventy have presented serious problems, the chief of these being bed-wetting and unmanageableness. I have seen at first hand the work that is being done for the "Women's Voluntary Service" by an experienced child guidance worker in assisting the children to settle down to their new life and in mitigating the hardships of the foster parents. Much has already been done by reshuffling billets. For instance, foster homes that cannot tolerate bed-wetting can easily deal with stealing, whilst others who cannot put up with a child unable to use knife and fork do not mind a great noise and mess in the house. But this has been but one part of the child guidance worker's duties. The second has been to establish and run centres for the treatment of those children who are really anxious and psychologically ill. In her car the worker carries around play therapy apparatus from one centre to another. Thirdly, she has organized a hostel for about twenty of the completely "unbilletable" and difficult children, and I have seen them as a happy noisy crowd under the supervision of a thoroughly understanding teacher, nurse, and housekeeper. Some children cease to be problems when placed in the care of more experienced people, whilst others require—and are receiving—individual psychological treatment. The success of the work can be gauged from the fact that among sixteen children sent to the hostel for bed-wetting there are now only two wet beds per night.

It is to be hoped that other areas will follow this example, since individual difficulties of this kind are seriously interfering with the success of evacuation schemes—schemes which have cost the country a great deal of trouble and expense.—I am, etc.,

Southampton, Oct. 19. S. L. Yates.

Sir,—In reference to your admiration for the "successful exodus" and the adverse comments of your correspondents in reference to the L.C.C. and the education authority, I write to point out that criticism should be directed chiefly to the Ministry of Health. My reasons are these:

Last autumn, after a wireless broadcast about the Ministry's scheme for evacuation, I was visited by a volunteer representing the local health authority inquiring about the number of rooms in my house, etc. I told her the scheme as announced on the wireless struck me as excellent for the distribution of vermin throughout the countryside, and asked her what methods the local authority had in view to safeguard the neighbourhood. She replied she had never thought of it, did not think anyone had, and did not believe the danger existed because (she argued) the children would be under the care of teachers and under medical inspection. I told her I could not believe the health services could have so far improved conditions since I retired from practice as to have eliminated the danger, and my experience had taught me that teachers, with their attention concentrated on teaching, very often failed to observe obvious vermin, let alone the eggs of vermin. She promised to report my warning to the local authority.

At the end of July, or early half of August last, I called on the local officer in charge of the scheme. He informed me that my warning had been noted in a book, but he was satisfied there was no danger because the health authority of the evacuating area had had the matter in hand for months. I repeated I thought it a matter to be thought of. When evacuees arrived I was informed many were verminous. One girl volunteer told me she was struck by sores on some children she had to carry and dump on a hostess. This would have been bad enough. But, further, there were women among them who soiled their beds with urine and faeces.

I submit it would have been a simple thing for the Ministry of Health to ascertain from each evacuating area the approximate number of their slum population, and have instructed each corresponding reception area to be prepared to receive that number of people not fit to be billeted in any home. They should have given advice as to how best to tackle the problem instead of leading the local authority to suppose there was no danger because the health authority of the evacuating area had the matter in hand for months. How could small towns and villages be prepared without receiving such information and advice? As a member of the medical profession I am deeply humiliated by the lack of foresight and sympathy displayed by the Ministry of Health, which is the responsible authority in the matter under consideration.—I am, etc.,

Bangor, Oct. 18. Erie Evans.

Intussusception from Meckel's Diverticulum

Sir,—The three notes on intussusception from a Meckel's diverticulum published in the *Journal* of March 10 and 17 and April 21 emphasize the rarity and the interest of this condition. The following describes the treatment of such a case by a two-stage operation for a moribund patient.

A boy aged 1½ years was admitted to hospital cold, almost pulseless, and dehydrated. He presented the classical symptoms and signs of an intussusception with an abdominal tumour and the passage of blood per rectum. After restoratives, the operation was undertaken and the intussusception was confirmed but only reduced partially. The apex was found to be a Meckel's diverticulum which could not be unfolded owing to the gross oedema about it. However, enough of the invagination had been undone to permit the normal passage of the bowel contents; besides which the child's state was so parlous that extension of the operation to excise the protrusion was clearly prohibited. The diverticulum was anchored by a single catgut suture to the lower end of the abdominal incision and the wound was closed. A blood transfusion and intravenous saline were given and the child rallied.

Three weeks later the wound was reopened and the diverticulum was readily delivered. The oedema had subsided, the invagination was still present and still irreducible. It was excised and an uneventful recovery ensued.—I am, etc.,

Oct. 13. Harold Dodd.

Sir,—In your issue of October 7 (p. 722) Mr. R. Stuppel describes an interesting case of irreducible intussusception due to a Meckel's diverticulum, and goes on to discuss the principles of treatment of these cases. He concludes that it is unjustifiable to leave an unreduced intussusception in the abdomen after performing a short circuit, and states that "to excise the tumour . . . cannot materially add to the shock of the operation." This conclusion, I believe, requires some qualification. It has been shown that the mortality rate of resection for irreducible intussusception in infants is very high, and, in fact, approaches 100 per cent.

In my 1935 report (*Lancet*, 2, 992) of three cases, referred to by Mr. Stuppel, the successful treatment by short-circuiting anastomosis was based on the facts that the cause of death in the majority of untreated cases is intestinal obstruction and that peritonitis due to gangrene of the intussusceptum is a rare complication, and it was suggested that this treatment gave the best chance of survival. Although, of course, the risk of peritonitis cannot be altogether excluded, this risk is much less than that of resection in children under 3 years of age. As older children are better able than infants to withstand major abdominal operations, the slight risk of peritonitis when the intussusception is left *in situ* is, perhaps, an argument in favour of resection in their case, but it is justifiable to take this risk when dealing with very young children in view of the high mortality following resection. The contention that an intestinal resection following an anastomosis does not materially add to the shock of the operation cannot be accepted.

By a coincidence, I have during this past week operated on an irreducible intussusception in a child of 2½ years; a short circuit without resection was performed, and up to the present time the progress has been satisfactory.—I am, etc.,

Reading, Oct. 16. A. Elliot Smith.

Sir,—I wish to report another case of acute intussusception caused by a Meckel's diverticulum following that of Mr. R. Stuppel's in your issue of October 7 (p. 722). Although the condition is apparently not uncommon, it is insufficiently reported, especially in view of its high mortality and the varied opinion as to its treatment. This case is similar to Mr. Stuppel's and gives a further method of treatment where a primary resection is inadvisable.

In October, 1938, a girl aged 4 was admitted as an "emergency" with an abdominal tumour. She had been ill with some abdominal pain for four days, and acute pain associated with vomiting for twenty-four hours, which had ceased for the last few hours. There-had never been any previous attacks so far as could be made out. There had been no passage of blood or mucus per rectum, and the bowels had been open the day before.

On examination she was a very pale, dehydrated child in no obvious pain. Temperature was 98° F. and her pulse rate 120. There was very little abdominal distension apart from an obvious tumour in the umbilical region about 2½ by 4 inches and freely mobile. It did not readily suggest an intussusception from its shape, but this was considered to be the likely diagnosis. There was nothing to be felt per rectum.

Operation was performed under gas-and-oxygen anaesthesia. Subumbilical incision was made and the tumour delivered. It consisted of the last part of the ileum and was confined to it. In spite of trying various methods it could not be reduced, and there was great risk of splitting the ensheathing layer, which was congested and rather distended with its contents but otherwise healthy. A side-to-side anastomosis was made between the afferent and efferent loops a short distance from the tumour. It was not justifiable to resect the tumour owing to the grave condition of the child, so the abdomen was closed with the tumour outside the abdominal wall, as in a Mikulicz operation. Intravenous saline was given, and the post-operative course never really gave rise to any anxiety. The bowels were open the following day and for the rest of her time in hospital. Four days later the tumour was removed with the diathermy knife under gas and oxygen. Although there was very little leakage from the ileostomy it was sufficient to produce some digestive appearances of the wound margin. A further operation was performed to close the fistula, which was done three weeks after the original operation by a simple suture, the peritoneal cavity not being opened. From then on there was an uninterrupted recovery and there were no ill effects when seen recently.

The specimen removed was similar to the one reported by Mr. Stuppel with an equally long gangrenous, perforated, and invaginated Meckel's diverticulum three inches long. The whole tumour had been twisted on itself, thus losing its sausage shape.

Although it may be possible to resect the intestine, preceded by a preliminary lateral anastomosis as outlined by Mr. Stuppel, there will be some cases in which this is not always considered advisable, as it appeared in the case above. The bitter experiences of Mr. Stuppel's case showed that the returning of the mass to the abdominal cavity is unjustifiable, although Mr. Elliot Smith's cases were successful. Viability of the ensheathing layer gives no indication as to the viability of the entering and returning layers. Also, suturing the layers together or hoping for a spontaneous cure cannot be relied on and does not seem to be devoid of a definite risk.

In view of the high mortality of resection of the intestine in children it would be interesting to hear the views of others who have tried resection by stages.—I am, etc.,

King's Lynn, Oct. 21. John O. Harrison.

Varicosities of Veins

Sir,—Professor Lambert Rogers (*Journal*, August 19, p. 383) in his paper on the treatment of varicosities of veins stressed the importance of tying the saphenous vein above its highest tributary. In your issue of September 9 (p. 581) Dr. W. D. Park suggests that it is easier and equally effective to ligature the vein above the highest dilated part. Personally, I am in entire agreement with Professor Rogers, and my own experience of combined ligature and injection in 329 cases has convinced me that the method advocated by Dr. Park is at least as difficult, and is followed by a large number of late recurrences.

In 1932, disappointed with the late results of injection only in advanced cases of varicose veins, I began to use the operation which Dr. Park now suggests. In 160 cases I tied the vein just above the highest dilated part and at the same time injected sodium morrhuate distally. The immediate results were excellent, and I agree with Dr. Park that many cases require no more injections or apparently less than if the vein is tied at the saphenous opening. It was only after a year or so that recurrences from this operation began to appear. So far eighteen, or 20 per cent., of these cases have developed gross recurrences; the shortest period before recurrence was six months, the longest about three years.

I do not think there can be any argument that on anatomical and physiological grounds ligature at the saphenous opening is the more radical operation. The operation at the saphenous opening is also, in my opinion, an easier one than the distal ligature because we have a definite fixed surface marking for the saphenous opening, while it is remarkable how often it is difficult to find the lower vein in the leg, even when its position has been carefully marked on the skin beforehand. Many surgeons consider that the proximal ligation of the saphenous vein close to the femoral trunk is fraught with danger. Personally, I consider that this risk has been grossly exaggerated. I have never seen any complications which could be attributed to high ligation in 169 cases, most of which were allowed to go home on the day of the operation, and I know of many colleagues who have had as fortunate an experience.

I have been very conscious of the fact that if sodium morrhuate has been injected after saphenous-femoral ligation the sclerosing effect is very limited. It appeared to me that this difficulty could only be overcome by injecting large doses of the sclerosing fluid and massaging it down the vein or by passing a long needle or catheter down the vein and injecting as it is being withdrawn. Sodium morrhuate, unfortunately, cannot be used in large doses, and, moreover, it is my experience that it produces more perivenitis and a more massive clot than the other sclerosing fluids. For the last five years I have used sodium salicylate in 30 per cent. solution and have found the results to be very satisfactory; it can be used with safety in doses of 10 or more c.cm. and produces the minimum amount of perivenitis and thickening. Unfortunately sodium salicylate produces a severe cramp-like pain in the leg, but this does not last for more than a minute or two.

I find that the best method of spreading the sclerosing fluid over the largest area of the varicosities is to pass a ureteric catheter down the vein as far as it will go and then inject the fluid while the catheter is slowly withdrawn. As the catheter is passed down the vein it will be felt to catch in the valves, but with a little manipulation it will slip on.—I am, etc.,

Liverpool, October 15. J. B. Oldham.

Melted Wax in Therapeutics

Sir,—Melted wax has been used for some years for the purpose of applying heat to rheumatic joints. For the last four years some of us at the local hospital and in our practices have extended its use to various inflammatory conditions such as local sepsis, pleurisy, etc. The immediate local treatment of such conditions may be summarized as: first, immobilization to prevent the spread of infection, and, secondly, the application of heat to increase blood supply and mobilize body defences to the site affected. In my opinion melted wax is by far the most efficient way of applying heat that we possess. The inflamed hand or finger which leaves the surgeon uncertain as to when and where to incise will often be induced to localize within twenty-four or forty-eight hours into a large pus blister which can be dealt with without anaesthesia.

In the treatment of inflammation it is not sufficient to apply the wax for an hour at a time. It is best to put it on in layers in the usual way with a brush and incorporate some cotton-wool in the last layer. Such an application need only be changed every twelve hours, and is light and comforting to the patient. Hard paraffin wax can be obtained from the chemist at about 8d. a pound with a melting-point varying from 120° to 140° F. As it can be used repeatedly the cost of each application is almost negligible.—I am, etc.,

Ashford, Kent, Oct. 10. E. Scott, M.D.

Cisternal or Lumbar Puncture.—Weidner favours lumbar puncture, having had two cases in which death followed cisternal puncture; in one case death was caused by a subarachnoid haemorrhage. After lumbar puncture he injects physiological saline into the spinal canal (four-fifths of the amount of cerebrospinal fluid withdrawn) in order to restore the intraspinal pressure to its previous level and to prevent the headache which commonly follows lumbar puncture.—K. Weidner.—*Klin. Wschr.*, June 30, 1938, **28**, 911.

Obituary

EDWARD PALMER POULTON, D.M., F.R.C.P.

Senior Physician to Guy's Hospital

Edward Palmer Poulton, who died on October 18, was the elder son of Sir Edward Poulton, F.R.S., Hope Professor of Zoology at the University of Oxford from 1893 to 1933. He was born at Oxford in 1883 and was educated at Rugby, where he was a science exhibitioner, and Balliol, where he was a science scholar. He obtained a second class in the final honour school of chemistry in 1905. He stayed two additional years in Oxford before going to Guy's in order to work for his first M.B., and there came under the influence of Haldane. This together with his early training in chemistry had a profound effect on his future career as a scientific physician. In 1911 he gained the Radcliffe Travelling Fellowship, and after finishing his house appointments at Guy's he went to Munich, where he worked under Fr. von Müller, the greatest German physician of the twentieth century. He returned to Guy's in 1912 as demonstrator of physiology, and the next year he was appointed medical registrar. In 1914 he was elected assistant physician and gained a Beit Memorial Research Fellowship. In 1918 he was elected Fellow of the Royal College of Physicians and delivered the Goulstonian Lecture on recent views on diabetes mellitus and on the significance of acidosis in disease. In 1921 he was awarded the Radcliffe Prize by the University of Oxford for original research, and in 1928 he was Oliver Sharpey Lecturer at the Royal College of Physicians. In 1926 he was elected physician to Guy's. In July of this year he became senior physician, and under normal conditions the hospital would have had the benefit of his services in this capacity for four years. But the war led to the dispersal of the staff, and students and Poulton joined the section which went to Pembury, near Tunbridge Wells, where he was taking a leading part in the clinical instruction of the students at the time of his untimely death.

Poulton was interested in many branches of medicine, but he always approached the study of disease from the point of view of a biochemist. Like Pavy sixty years earlier, he made Guy's a centre for research in diabetes, and he made many important contributions to our knowledge of the disease and to its treatment both before and after the discovery of insulin. He believed that the usual method of measuring the basal metabolism rate depended upon false principles, and he made elaborate chemical and mathematical studies with the object of putting the subject on a more accurate and scientific basis. He was an expert in dietetics and wrote a useful book on the dietetic treatment of diabetes and obesity with a large collection of recipes. Poulton's early work with Haldane had made him interested in the chemistry of respiration, and his most valuable contribution to practical medicine was in connexion with oxygen therapy. He was tireless in devising improved methods for its effective administration. He showed how oxygen, when given in sufficient concentration, was of enormous value in many conditions in which hitherto it had never been employed. His oxygen tent came into use in the majority of large hospitals, and he arranged for a service by which an apparatus could be sent with a skilled technician to a hospital or private house anywhere in the country. This work must have saved countless lives, and, though simpler methods of giving oxygen are now generally used instead of the tent, our knowledge of the need for high concentrations and of the many indications for oxygen therapy are largely the result of his unceasing investigations on the subject.

Poulton was a first-class hockey player in his student days, gaining his half-blue for Oxford in 1905 and 1906, but a succession of illnesses restricted his physical activity in later years. However, he never allowed this to interfere with his work at Guy's. He was a better biochemist than clinician, and his enjoyment of teaching did not always receive the appreciation it deserved. He was a regular attendant at meetings of the Royal Society of Medicine, the Association of British Physicians, and the Medical Research Club, and he was one of the few physicians who rarely missed a meeting of the Physiological Society. He received four grants for research from the British Medical Association, and was secretary of the Section of Medicine at Bradford in 1924, vice-president of the Section of Therapeutics at Edinburgh 1927, and vice-president of the Section of Medicine at Eastbourne in 1931.

After the death of Sir Frederick Taylor, Poulton was asked to edit the twelfth edition of his *Practice of Medicine*, and he was also responsible for the three further editions which have appeared since then. The book has deservedly retained its popularity among students, as Poulton put in an enormous amount of work to keep it completely up to date, but whereas in Taylor's time it was still possible for one man to write the whole of a book on medicine by himself Poulton wisely obtained the help of colleagues to look after such special subjects as dermatology and neurology. The dogmatic style of the earlier editions was in remarkable contrast with the character of Taylor's bedside teaching, but the later editions clearly showed Poulton's special interest in biochemistry and his original and often unorthodox views on treatment.

Everybody liked Poulton, and his death comes as a severe blow to the hospital he served so well. At the same time it removes an outstanding personality from the medical life of the country.

In 1911 Poulton married Elfrida, daughter of the late Charles Maclean of Glenearn. He had three sons, the eldest of whom is in his father's profession, and two daughters.

A. F. H.

[The photograph reproduced is by Elliott and Fry, Ltd.]

A. T. PITTS, D.S.O., M.R.C.S., L.D.S.

Our sympathies will be with our colleagues of the dental profession for the loss that they have sustained by the unexpected and early death of Mr. Arthur Thomas Pitts, who had done so much for the British Dental Association during the past years.

The abilities of Mr. Pitts were speedily recognized both by his teachers and his fellow students at the Middlesex Hospital. His was an ability which included not only the power to grasp the accumulated wisdom and experience of medical practice and teaching put before him in the laboratories, the lecture rooms, and in the hospital clinics as becometh a good student, but also the finer power of giving a clear expression to this knowledge. He could write. So that in his later student days he became the editor of the *Middlesex Hospital Journal*, and an exceptionally good editor he proved himself to be. This early work of his was as it were the signpost to his best and most valuable work for his professional colleagues. Soon after the end of the last war he became the scientific editor of the *British Dental Journal*, and his work in that field proved to be of a high order and of real service. The loss of these services of his will be felt by all members of his profession.

His attainments in the practice of dental surgery were recognized by his appointment as dental surgeon to the Royal Dental Hospital, and also to the Middlesex Hospital; and as examiner in dental surgery to the Royal College of Surgeons of England and to the University of Liverpool. His abilities in general medicine and in executive power were proved by his work in the last war. He served from 1914 to 1919 and reached the rank of lieutenant-colonel in 1917. He was O.C. of the 4th Cavalry Field Ambulance, B.E.F. For his services he was mentioned twice in dispatches and awarded the D.S.O. As a man he was of the gentlest and most kindly nature. He was always willing to help others. And he did these services in such fashion that the recipient of his aid also received the impression that he was conferring a favour upon Pitts by allowing him to give this kindly help. He was truly a gentle man.

N. Bishop Harman.

BEDFORD FENWICK, M.D.

Consulting Gynaecologist, Hospital for Women, Soho

Dr. Bedford Fenwick, who died at Cambridge Gate, Regent's Park, London, on October 14, was a member of a well-known medical family. His father, Samuel Fenwick, M.D., practised at North Shields and in Harley Street.

Born on March 2, 1855, Bedford Fenwick received his medical education at the London Hospital and at Newcastle-upon-Tyne, and graduated M.B. of the University of Durham in 1877, proceeding to the M.D. in 1880 and taking the M.R.C.P.Lond. in 1881. After postgraduate study in Leipzig, Berlin, and Paris, he settled in practice in London and was elected assistant physician to the City of London Hospital for Diseases of the Chest. Specializing later in gynaecology he was for many years a member of the visiting staff of the Hospital for Women, Soho, and Editor of the *British Gynaecological Journal*. Dr. Fenwick married in 1887 Ethel Gordon Manson on her retirement from the post of matron of St. Bartholomew's Hospital. He became trustee and treasurer of the British College of Nurses, one of the many institutions, national and international, founded and presided over by Mrs. Bedford Fenwick, and he took a warm interest in the *British Journal of Nursing*, of which she has long been editor. He edited the sixth edition of the *Student's Guide to Medical Diagnosis* in 1886 and wrote several books—*Nursing of Chest Diseases*, 1901; *Common Complaints of Women*, second edition, 1920; and *Uterine Fibroids and Pelvic Tumours*, third edition, 1920.

Mr. Thomas Morrell-Thomas, who died on October 9 at the age of 68, was educated at Aberystwyth College and Guy's Hospital, and graduated M.B., B.S.Lond., with first-class honours, in 1895. He took the M.S. soon afterwards and the M.D. and the F.R.C.S. in 1897. Having served as assistant demonstrator of anatomy and house-surgeon at Guy's Hospital, he joined his uncle, the late Sir Garrod Thomas, in Newport, Monmouthshire, and was elected to the surgical staff of the Royal Gwent Hospital. Mr. Morrell-Thomas combined the work of general practitioner and surgeon, and held many appointments, including those of visiting surgeon to the Monmouthshire and Newport Mental Hospitals, and consulting surgeon to the Welsh National Memorial Hospital, Newport. During the last war he held a commission as major R.A.M.C.(T.) on the *à la suite* staff of the 3rd Western General Hospital. He joined the British Medical Association in 1898, and was a past president of the Newport Medical Society.

Dr. Frank Allan Roberts, who died suddenly on October 9 at Houghton House, Brighouse, Yorks, aged 73, was the elder son of Samuel Drake Roberts of Rawfolds, Cleckheaton, and had his professional training at the Yorkshire College, Leeds. After taking the English Conjoint diplomas in 1891 he served as house-physician and resident medical officer at the General Infirmary at Leeds, and resident medical officer to the Leeds Public Dispensary. In 1894 he graduated M.D.Lond., and some years later settled in practice at Brighouse. For many years he was deputy medical superintendent of the Clifton Hospital, and he had been a member of the British Medical Association for nearly half a century.

We regret to announce the death of Dr. John Joseph Tisdall, which took place at Boughton Hall, Chester, on October 11, in his eightieth year. He studied medicine at Liverpool and Edinburgh, and qualified L.R.C.P., L.R.C.S.Ed. and L.M. in 1882. He joined the British Medical Association in 1896, and always took a keen interest in the affairs of his profession. For many years while in private practice, and later while superintendent of Tue Brook Villa Liverpool, he attended the Annual Representative Meetings; he was a representative of Liverpool in 1903, in 1914–17, in 1919, and in 1921. His son is Dr. Charles J. Tisdall, resident physician at Boughton Hall, Chester.

We have received the following further particulars of the career of Dr. Augustus Mayberry Whitestone, whose death was recorded in last week's *Journal*. He practised at Hollingbourne, Kent, and was medical officer to Hollingbourne Union for thirty-six years, when being knocked down by a motor cycle he was forced to retire. Returning to live among his old friends in 1936, in failing health, he received a warm welcome, owing to his cheery nature and constant kindliness. A friend who helped him with his work in 1924, when he was recovering from pneumonia, writes: "I have the happiest memories of that time, of his sweet nature and how he taught me to run a practice. I admired him and his robust outlook on life and on his work. In my own medical life I have often tried to deal with things in his way. It is in contacts like these that tradition in our profession is handed on, and I am fortunate that I was privileged to meet him in that way." Dr. Whitestone married in 1894 a daughter of the late Major-General Sir Frederic Goldsmid, and has one son, a colonel in the Royal Engineers, now serving at the front.

The death of Mr. Ernest Harding-Freeland took place within a month of his retirement from the post of medical officer of the Isle of Thanet Joint Isolation Hospital at Haine, which he had held for thirteen years. The son of a naval officer, Commander J. O. Freeland, he studied medicine at the Middlesex Hospital, and qualified M.R.C.S., L.R.C.P. in 1885. After holding a number of hospital posts, including those of house-surgeon at the Middlesex, surgical registrar at the Royal National Orthopaedic, and resident medical officer at the Royal Waterloo Hospital for Children and Women, he took the F.R.C.S. in 1897. During the war he served with the temporary rank of captain R.A.M.C., and afterwards practised at Herne Bay before moving to Haine, near Ramsgate. Mr. Harding-Freeland had been a member of the British Medical Association for forty years.

Aspiration Therapy of Tuberculous Cavities.—This is a preliminary communication, with a detailed case report, of a method of treatment that will probably excite much interest.—Aspiration Therapy of Tuberculous Pulmonary Cavities. V. Monaldi.—*Z. Tuberk.*, May, 1939, 82, Heft 5, 273.

Medico-Legal

PROCAINE OR PERCAINE?

A doctor desired to administer a local anaesthetic to a patient suffering from arthritis. He went to a firm of chemists and asked one of the dispensers for a drug. About midday the bottle arrived labelled: "Not to be taken. Sterile solution of percaine, 2 per cent. 50 c.cm. Poison." He read the label and opened the bottle, and referred to the manufacturer's catalogue, in which he found listed a 2 per cent. solution of percaine for use "exclusively in surface anaesthesia." He decided that it would serve his purpose, and injected about 12 c.cm. around the patient's shoulder. Within five minutes she said she felt faint; she then went into convulsions and died in about half an hour from heart failure and acute oedema of the lungs.

At the inquest before the Bournemouth coroner, held on October 5, the doctor said he had asked the dispenser for a 2 per cent. solution of procaine. He did not say what he wanted it for, and was not asked to sign the poisons book. He had thought that use for surface anaesthesia did not exclude subcutaneous injection. He produced a list which he had made as a personal memorandum for use that morning: it contained the name "procaine." It was quite usual, he said, to ask verbally for procaine; in a dilution under 10 per cent. it was not a First Schedule poison. (Poisons in the First Schedule to the Poisons Rules must be signed for by the purchaser in the poisons book or entered in the prescription book.) When he had gone to the chemists he had not known there was such a preparation as 2 per cent. percaine, though he had heard of the name. He knew that procaine was a normal local anaesthetic, and that percaine was more commonly used as a spinal anaesthetic, and that if he had asked for percaine he would have had to sign the poisons book. In cross-examination he said he did not know that percaine was at least ten times more toxic than procaine.

The dispenser, in evidence, said that the doctor asked for percaine, and that he himself entered in the day-book a sale of percaine as soon as the doctor left the shop. He did not know at the time that percaine was a First Schedule poison in weaker strength than 10 per cent., or that there was a considerable difference between 2 per cent. percaine and 2 per cent. procaine. A qualified pharmacist employed by the firm said that after the doctor left he and the dispenser discussed the amount of percaine crystals which should be put into the water for the solution. According to the maker's price list a 2 per cent. solution of percaine was a First Schedule poison, but at that time he did not think it was. Another pharmacist said he had also checked the quantity, and had not been fully aware that percaine was in the First Schedule. A medical representative of the manufacturers of percaine said it was a synthetic local anaesthetic with properties like those of cocaine, and might be injected into the tissues, but the 2 per cent. solution was not safe for injection. The proper concentration in this case would have been one-tenth of 1 per cent.; 2 per cent. procaine would have been suitable. The maximum safe dose for this patient would have been about 60 mg. of percaine, but the doctor had given 240 mg. The drug should not have been dispensed without a written order. A pathologist agreed that the drug was a proper one to administer, but the strength had been too great.

The coroner advised the jury that if they were in doubt whether the doctor had been guilty of criminal negligence they must give him the benefit of that doubt. He pointed to the frankness of the doctor's admission of his mistake. It was dangerous to give a verbal order for a drug, and the doctor, when he found that the chemist had sent him percaine, could easily have rung up to say that it was not what he had ordered. The jury returned a verdict of death from misadventure with a degree of negligence on the part of the chemist and the doctor, but not criminal negligence.

The Question of Negligence

The degree of negligence which a jury may regard as criminal has been dealt with very fully by the courts, particularly by the Lord Chief Justice in R. *v.* Bateman (1925). The carelessness has to be quite unusually bad, or aggravated in some unusual way, to amount to criminal negligence, and a verdict of criminal negligence against a doctor is a very rare thing. As the coroner remarked, the death was due to an unusual chain of misfortunes. Perhaps the most important factor was the similarity of the two names. Procaine is a scientific name for a local anaesthetic of low toxicity, and is mentioned in the *British Pharmacopoeia*. Percaine is a proprietary name applied by a well-known firm of drug manufacturers to a synthetic compound with properties similar to those of cocaine, one of the most powerful local anaesthetics obtainable. The evidence suggested that the doctor had not the vital distinction between the two names present to his mind, and the chemists did not realize they were dealing with such a dangerous substance, or indeed that it was a First Schedule poison. They were within the law in dispensing percaine on a doctor's verbal order if they made, as they did, a suitable entry in the prescription book. Procaine, though it may only be sold by a qualified pharmacist, may be sold to a lay purchaser without restriction or record. This accident might have been avoided if the doctor had written a prescription for the drug instead of relying on a request by word of mouth. Verbal prescription is probably harmless in the vast majority of cases, but an appreciable number of accidents can be directly traced to it.

STATUTORY PROTECTION OF MEDICAL OFFICERS

In order to protect public authorities from claims made against them a long time after the facts on which they are based occur, Parliament passed in 1893 the Public Authorities Protection Act. An action against an ordinary citizen may as a general rule be brought at any time within six years, but this Act limits the period for bringing an action against a public authority to six months. It applies to "any action . . . against any person or any act done in pursuance or execution or intended execution of any Act of Parliament or of any public duty or authority, or in respect of any alleged neglect or default in the execution of any such act, duty, or authority." A child was severely burnt during an operation for the removal of tonsils and adenoids at the West Middlesex Hospital; by her mother, suing as her next friend, she claimed damages from the surgeon and the anaesthetist, but did not bring her action within six months. The doctors denied negligence and relied on the protection of the Act. The patient maintained that it did not apply to them. It would, her advisers said, have protected the Middlesex County Council, but they were not responsible for the actions of these doctors. When doctors are employed by a local authority they are not servants carrying out the orders of their employer; they act on their own discretion in accordance with their skill, and are independent contractors. Therefore, said the patient, they cannot claim the protection which the Act gives to the council employing them.

Counsel for the doctors submitted that the Act clearly protects individuals as well as public bodies. Mr. Justice Atkinson, trying the preliminary point of law, remarked (*Times*, October 6, 1939) that it was curious that the precise point seemed never to have been argued before. A servant or agent of a local authority has long been recognized to be entitled to the same protection as the local authority itself, but these doctors were not servants or agents. He pointed, however, to an admission in Freeborn *v.* Leeming (1926) that a medical officer is entitled to the same protection as a public authority; and to Mr. Justice McCardie's remark in Venn *v.* Tedesco (1926) that it was conceded that medical officers were within the class of individuals covered by the Act. That judge, said his lordship, would never have referred to that admission unless he had thought it was right. In those cases, therefore, the law had been regarded as settled, and he could not now rule differently unless he thought they were wrong. In fact, he thought they were right, and that as the doctors were acting in pursuance of a duty laid on the Council they were entitled to the benefit of the Act.

INSANITY AND CIVIL RESPONSIBILITY

Insanity as a defence to a criminal charge—usually murder—is familiar. By the "MacNaghten rule" a man is responsible for his actions unless by reason of disease of the mind he did not know what he was doing or that what he was doing was wrong. It has recently been held in the Divorce Court[1] that intention is a necessary ingredient of the matrimonial offences of cruelty or desertion, and that if the respondent, by reason of insanity, is incapable of forming the intention to be cruel or of retaining the intention to desert, the petition on those grounds must fail.

The degree of insanity which will afford a sufficient answer to a civil action of negligence has been discussed interestingly in a county court case by his honour Judge Konstam, K.C.[2] A cab driver suddenly swerved from his proper side and ran into a lorry. He immediately got out and stabbed himself several times with a carving knife. He said he had swerved to avoid a cyclist, and the medical evidence showed that no cyclist had been there and that the man suffered from hallucinations and delusions. The judge was satisfied that the swerve was due to the sudden impulse of an unbalanced mind, but found that the driver understood the nature and consequences of his act. He remarked that the question was not covered by any direct or binding authority. Lord Esher, in Hanbury *v.* Hanbury (1892), treated the test of responsibility as the same in criminal and in civil actions, but no question of negligence arose in that case. His honour quoted textbook writers who said that the question for the jury was whether the defendant was sufficiently self-possessed to be capable of taking care, and that the lunacy must be so extreme as to deprive its victim of all power of deliberate choice. Sudden illness, other than mental, which deprives its victim of the power of using skill and care is a good defence. The learned judge therefore concluded that there exists in law a sound distinction between negligence and other grounds of action. As this driver was not sufficiently self-possessed to be capable of taking care, and the swerve was not the conscious act of his volition, neither he nor his employers could be held responsible.

This judgment is not a binding authority, but seems to rest on solid foundations and to point to the tests which the High Court would probably apply in a similar case.

Experimental Pulmonary Embolism.—Intravenous injection of air, fat, or a starch suspension in rabbits caused changes in the electrocardiogram similar to those found in infarct of the heart muscle, and also changes typical of a right bundle-branch block (old nomenclature). In the majority of experiments the electrocardiogram returned to normal after recovery from the embolism, although widespread necroses were present in the wall of the right ventricle. These changes seem to be due to the sudden overloading of the right ventricle.—Electrocardiographic and Histological Examination of Heart in Experimental Pulmonary Embolism produced by Air, Fat, or by Starch Suspension: R. Walder.—*Beitr. path. Anat.* May 26, 1939, **102**, 485.

The Services

HEALTH OF THE ARMY IN PEACE

The report on the health of the Army for 1937[1] is the seventy-third such volume, which means that the first appeared in the 'sixties, when the sanitary reforms brought about by the Sidney Herbert Commission were beginning to have their effect. The present report gives us a picture of an Army healthier than it has ever been during that three-quarters of a century history. The same causes affect the health of the military and of the civil population, but conditions of selection and discipline in the Army favour a still higher standard, while, on the other hand, the soldier, particularly at foreign stations, faces certain liabilities which make him a more likely prey to disease. Of both soldier and civilian the paradox holds good that at a moment when their protection from disease was most assured, their liability to wounds, injuries, and violent death was never greater. The onslaught of disease has been stayed, but this other Moloch, whose blind strokes no medical wisdom can avert, gets a new momentum.

Hospital Admissions

The rate of admissions to hospital in 1937 decreased by 14.1 per 1,000 of strength as compared with the previous year, and was only 21.5 per 1,000 higher than the rate for 1935, which was the lowest recorded since the great war; while the death ratio of 1.97 per 1,000 and the ratio of 6.8 for invalids discharged from the Service were absolutely the lowest. The principal causes of admission to hospitals were influenza, inflammation of areolar tissue (chiefly boils and carbuncles), inflammation of tonsils, and venereal diseases. Influenza shows a considerable increase over the previous year. It heads the list of causes of admission in all the home commands except the Western, where inflammation of tonsils has that pre-eminence. The principal cause of invalidity leading to discharge from the Army was tuberculosis. It is worth noting in passing that the Royal Army Medical Corps had almost the highest incidence of pulmonary tuberculosis to be found in any unit.

The effect of common ailments on military efficiency varies according to the station. In the home commands local injuries account for the greatest number of lost days. By far the most common of these were fractures of the tibia and/or fibula and the radius and/or ulna, followed by the carpus or metacarpus. In India the commonest cause was malaria, although the rate for malaria was down on the year, and indeed was the lowest yet recorded. The reasons assigned for this satisfactory result are less rainfall, earlier onset of cold weather, more intensive applications of anti-malarial measures, and greater co-operation between civil and military health administrations. The treatment of malaria in India is carried out sometimes with quinine and plasmoquine, but usually with atebrin followed by plasmoquine. It is pointed out that the investigations under the auspices of the Malaria Commission of the League of Nations Health Organization have confirmed in every respect the careful initial work undertaken in the military hospitals in India on the use of synthetic drugs.

Value of New Drugs

An extensive trial has been made at nearly all the Army stations of drugs of the sulphonamide group, and it is stated that these drugs have effected the saving of life by overcoming infections by the streptococcus—not necessarily haemolytic—notably severe attacks of erysipelas and septicaemia, and that less severe disorders, such as pyelitis, cystitis, and other genito-urinary infections are rapidly cleared up by this form of treatment. Some forms of streptococcal tonsillitis have been found to get well quickly, while others appeared to resist the action of the drugs. Staphylococcal infections are not usually influenced, but one instance is recorded where staphylococcal septicaemia was rapidly brought under control. The reports from Army stations have encouraged the belief that this group of drugs will also reduce the mortality of cerebrospinal fever.

---

[1] H.M. Stationery Office. (2s. 6d. net, postage extra.)

As to venereal diseases, it is mentioned that the polyvalent vaccine of mixed gonococcal and secondary organisms was tried in several areas with some measure of success, but this again has been abandoned in favour of sulphanilamide, which has been used in the treatment of gonorrhoea at home and abroad with apparently satisfactory results. The evidence available, says the report, indicates that it is a great advance on any treatment hitherto adopted. The dermatological specialist at Aldershot states that the whole atmosphere of the gonorrhoea wards has altered with the introduction of this new remedy. The patients, instead of being dull and troublesome, are now cheerful and anxious to get on with their treatment.

An interesting report is forthcoming from the vaccine department of the Royal Army Medical College, which supplies vaccines for the use of both the Army and the Royal Air Force. Increased demands were made in 1937 for all types of vaccines except the mixed influenza and catarrh vaccine, which is no longer recommended as a routine prophylactic. Over 99 per cent. of the troops and their families who embarked for service over-seas availed themselves of typhoid-paratyphoid inoculation. Diphtheria in 1937 showed a remarkable decrease among the Army population; this is credited to the immunization of the Army children, 95 per cent. of whom are now immunized with toxoid-antitoxin floccules. In another part of the report a great deal of useful information is included on the pathological work in the military laboratories in India.

Medical Examination of Recruits

It will be remembered that in 1936 the War Office decided that an attempt should be made to recondition applicants for enlistment who were below the standards for weight and chest measurement. Hitherto these men had been rejected outright. A course of special training for under-developed lads and border-line recruits suffering from various defects was instituted, and of those who completed this course in 1937, 90.5 per cent. were subsequently passed as fit. The after-history of these squads has been studied, and has shown that about one-third of them continued to make steady progress, and in most of the others there was intermittent progress. The average height and weight of all recruits enlisted in the home commands, other than the Southern Command, was 66.5 in. and 130.63 lb. respectively, but in the Southern Command a system has been instituted whereby heights and weights are recorded in age groups, and the other commands are now to adopt the same system. The average increase of weight among recruits under training during the year was 9.17 lb. This figure shows a fairly steady increase year by year. The chief cause of rejection is disease of the middle ear, including deafness. This cause accounts for more than twice as many rejections as either of the next two principal causes—namely, loss or decay of many teeth and defective vision.

In the light of the events of 1939 the year 1937 must be described as a year of peace, yet various operations were taking place in different parts of the world and were causing concern to those who had in charge the health of the British Army. The war in Spain, for example, caused Gibraltar to be overcrowded with refugees. In Palestine a number of troops were kept in conditions of field service, but the general health was good, and, although parts of Palestine are malarious, the malaria was well controlled. In India active operations were in progress in Waziristan, in which British and Indian troops were engaged, but here again health was very good, and sick rates were only slightly in excess of those obtaining in times of peace. For the first time evacuation of casualties was carried out by air from Waziristan, which is on the North-West Frontier. The number evacuated by air was just over 100, and the time as compared with road and rail was shortened by about five-sixths. Finally, in the Far East there was not only a major war but a cholera epidemic. Conditions were at their worst in Shanghai, with an appalling lack of sanitation, but the British troops were apparently almost immune. Only at Shanghai did any cases of cholera occur among military personnel; these numbered only five, and were considered to be due to neglect of orders and consumption of ice-cream from an unauthorized source. The outbreak of cholera among the civil population led to a much larger quantity of cholera vaccine than usual being supplied from the Royal Army Medical College. A strain of *Vibrio cholerae* obtained from Shanghai was incorporated in the vaccine.

Attention is being paid in every command to the hygiene of Army barracks. It is mentioned that at Gibraltar the polishing of the barrack floors is thought to have contributed to a decrease in the respiratory group of diseases—coughs, colds, and sore throats—which fell from 171 to 111 per 1,000 of strength. Married quarters are being improved, maternity and child welfare centres for soldiers' families are multiplying, and the report touches on many matters which favourably affect the comfort and well-being of the soldier and those dependent on him. More than half this volume is taken up with separate reports from the eight commands at home and the thirteen countries abroad in which the British Army is stationed.

MENTIONS IN DISPATCHES

Operations in Waziristan

The King has approved the promotion of Major M. P. Power, O.B.E., M.C., R.A.M.C., to be Brevet Lieutenant-Colonel for distinguished services rendered in the field in connexion with the operations in Waziristan.

The names of Lieutenant-Colonel J. R. N. Warburton, M.C., R.A.M.C., Major M. P. Power, O.B.E., M.C., R.A.M.C., Captain W. M. Stewart, R.A.M.C., Lieutenant-Colonel R. A. Logan, I.M.S., and Assistant Surgeon (Second Class) R. J. A. Ronto, I.M.S., have been brought to notice by the Commander-in-Chief in India for distinguished services rendered in connexion with the operations in Waziristan.

Operations in Palestine

The names of Colonel A. Hood, C.B.E., R.A.M.C., Major J. W. Malcolm, O.B.E., M.C., R.A.M.C., Captain K. G. F. Mackenzie, R.A.M.C., and Flight Lieutenant L. M. Crooks, R.A.F.M.S., have been brought to notice in recognition of distinguished services rendered in connexion with recent operations in Palestine.

CASUALTIES IN THE MEDICAL SERVICES

Royal Navy

Probationary Surgeon Lieutenant **Herbert Julian Cornelius**, R.N.V.R., who lost his life when H.M.S. *Royal Oak* was sunk by a submarine in Scapa Flow on October 14, took the M.R.C.S., L.R.C.P. as recently as January, and the M.B., B.S. of the University of London in June. He was elected a member of the British Medical Association on June 6.

DEATHS IN THE SERVICES

Surgeon Rear-Admiral Sir **Patrick Brodie Handyside**, K.B.E., C.B., R.N. (ret.), died at Gullane on October 15, aged 79. He was born in March, 1860, and was educated at Edinburgh Academy and the University of Edinburgh, where he graduated M.B., C.M. in 1883. Entering the Royal Navy as assistant surgeon in 1884, he became fleet surgeon in 1903 and surgeon rear-admiral on April 17, 1917. He was made C.B. in 1918 and K.B.E. in 1919. In 1918 he also received the Japanese Order of the Sacred Treasure (Second Class). As surgeon of H.M.S. *Fox* he served in the campaign of 1898 in Sierra Leone, landed with a force which took Manah Salya and Kwalin and rescued a party of eighty refugees, receiving the West African medal, with clasp for Sierra Leone. He married Lilly Chester, daughter of Lieutenant-Colonel H. M. Blenkinsop, late I.M.S. He had been a member of the British Medical Association for forty-three years, and at the Annual Meeting of the Association held at Brighton in 1913 he was vice-president of the Navy, Army, and Ambulance Section.

Major-General **William Charles Hughan Forster**, C.I.E., I.M.S. (ret.), died suddenly at Northlew, Devon, on October 11, aged 65. He was born on June 15, 1874, and was educated at

Edinburgh University, where he graduated M.B., C.M., with honours, in 1896, subsequently taking the D.P.H. at Cambridge in 1899. After filling the posts of house-surgeon for out-patients at Edinburgh Royal Infirmary and assistant resident medical officer at the National Hospital for Consumption, Ventnor, he entered the Indian Medical Service as lieutenant on July 27, 1899, attaining the rank of colonel on November 27, 1927, and of major-general on November 5, 1929. He retired on July 19, 1933. After four years of military duty he entered civil employ in April, 1904, as deputy sanitary commissioner in the Punjab. In April, 1909, he was appointed professor of hygiene and pathology in the Lahore Medical College and in August, 1918, became sanitary commissioner of the Punjab, the title of his office being changed to director of public health in November, 1921. On promotion to the administrative grade in 1927 he was posted to the inspector-generalship if civil hospitals in Burma, and in November, 1929, he was promoted to surgeon-general of Bombay, with the rank of major-general. In 1932–3 he was a member of the Bombay Legislative Council. He served on the North-West Frontier of India in the Waziristan campaign of 1901–2, receiving the frontier medal with a clasp. He was the author of several articles in *Scientific Memoirs*.

Lieutenant-Colonel THOMAS BIGGAM, R.A.M.C. (ret.), was born on January 15, 1874, and was educated at the University of Edinburgh, where he graduated M.B., Ch.B. in 1897. He entered the R.A.M.C. as lieutenant on April 25, 1900, became lieutenant-colonel on December 26, 1917, and retired on April 30, 1920. He served in the South African War, when he took part in operations in Cape Colony in 1900, and in the China War of 1900, receiving the medal.

Lieutenant-Colonel GILBERT HENRY DIVE, D.S.O., R.A.M.C. (ret.), was born in New Zealand on May 29, 1882, and was educated at Wanganui College, the University of Otago, and St. Bartholomew's Hospital. He took the M.R.C.S., L.R.C.P. in 1906, the M.R.C.P. in 1910, the D.P.H.Oxford in 1911, and the D.T.M. and H. of the English Colleges in 1925. He was house-physician at the West London Hospital in 1907 and house-surgeon at St. Bartholomew's Hospital in 1908–9. He entered the R.A.M.C. as lieutenant on July 31, 1909, and was clinical assistant to the professor of tropical medicine at the Military Hospital, Millbank, from 1910–12. He was a member of the British Expeditionary Force at Tsingtau in 1914, when he was mentioned in dispatches. He received a brevet majority on January 1, 1918, became major on July 31, 1921, and retired on May 29, 1937, shortly after his promotion to lieutenant-colonel. He served in Belgium and France in the war of 1914–18, when he was mentioned four times in dispatches. He received the D.S.O., the Medaille d'Honneur des Epidémies, and the Croix de Guerre. He had been a member of the British Medical Association since 1926.

Universities and Colleges

UNIVERSITY OF OXFORD

Sir Charles Sherrington, O.M., G.B.E., M.D., F.R.S., formerly Waynflete Professor of Physiology in the University, has been elected to an honorary Fellowship at Magdalen College.

UNIVERSITY OF CAMBRIDGE

The outgoing Vice-Chancellor, Professor H. R. Dean, M.D., F.R.C.P., Master of Trinity Hall, has been elected to the Council of the Senate.

At a congregation on October 21 the following medical degrees were conferred:

M.B., B.CHIR.—*N. Langdon-Down, *G. Oppenheimer, *D. L. Ridout, *A. M. Ogilvie, *G. S. Robinson, *A. Hargreaves, J. D. Younghusband, N. J. P. Hewlings, J. C. R. Nuttall-Smith, J. B. Murray, B. W. Powell, J. W. Shackle.

M.B.—*J. G. Warren, *L. J. Haydon.

* By proxy.

UNIVERSITY OF LONDON

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

The following candidates have been approved at the examination indicated:

ACADEMIC POSTGRADUATE DIPLOMA IN PUBLIC HEALTH.—Eva M. Cran, M. Daniels, Christina A. Gunn, S. M. H. Naqvi, G. H. Shaw, C. S. Thomson, N. V. Williams.

UNIVERSITY OF DURHAM

The following candidates have satisfied the examiners at the examination indicated:

FINAL M.B., B.S.—J. K. Adamson, M. Anderson, D. O. Bowes, Sheila D. M. Brown, W. E. Chapman, Margaret I. Dufty, F. N. C. Evans, R. J. Gray, J. D. S. Hethcote, S. Hickling, K. J. Higham, A. F. Hutchison, J. W. G. McDougall, E. A. Milner, R. H. Richardson, T. J. W. Robson, J. P. Simpson, T. D. Todd.

UNIVERSITY OF WALES

The following candidates have satisfied the examiners at the examination indicated:

DIPLOMA IN PUBLIC HEALTH.—*Part II:* H. L. Ackerman, D. J. Davies, S. H. Graham, C. T. Jones, J. J. O'Reilly, J. Paterson, H. R. Stubbins, *A. J. Thomas.

WELSH NATIONAL SCHOOL OF MEDICINE

The following candidates for the degrees of M.B., B.Ch. have satisfied the examiners at the examination indicated:

HYGIENE.—Mary E. Budding, Doreen M. E. Cranch, Enid Curran, *Joan B. Davies, T. C. H. Davies, I. L. R. Evans, D. I. Harries, Marguerite J. Hennelly, Helen C. Hodges, *D. D. Howell, O. Howell, D. H. Jenkins, R. T. Jenkins, G. A. Jones, J. V. Jones, Anne N. M. Llewhelin, J. E. Lloyd, Mary E. Lloyd, S. Love, Brenda M. Mead, D. G. Morris, R. E. Packer, Mary G. Powell, H. V. Roberts, D. C. Taylor, C. E. Thomas, T. Walker.

* With distinction.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

A quarterly meeting of the Council of the Royal College of Surgeons of England was held on October 12, with the President, Mr. Hugh Lett, in the chair.

Mr. R. St. Leger Brockman was re-elected a member of the Court of Examiners for a further period of five years.

Mr. H. F. Humphreys was re-elected a member of the Board of Examiners in Dental Surgery for a further period of five years.

It was decided to cancel the arrangements for holding the forthcoming primary examinations for the Fellowship in India, Egypt, and Australasia.

It was not found necessary to make any change in the regulations for the Primary or Final Fellowship examinations during the war.

It will be possible to conduct the Fellowship and dental examinations in London in the normal way on the next occasion.

The following arrangements have been made regarding Lectures: Arnott and Erasmus Wilson demonstrations, the autumn series has been cancelled; Hunterian Lectures, the lecturers will be asked to deliver their lectures if able to do so, if unable, they may publish the lecture and use the title "Hunterian Professor"; Moynihan Lecture, to be given by Professor Ernest W. Hey Groves in March, 1940; Thomas Vicary Lecture, to be given by Sir Walter Langdon-Brown as arranged on November 30, but at 3 p.m.; Bradshaw Lecture, to be given by Sir James Walton as arranged on December 14, but at 3.30 p.m.

The Licence in Dental Surgery

Until further notice the following relaxation in the regulations for admission to the examinations for the L.D.S., R.C.S., will be effective:

1. The two-years instruction in dental mechanics is reduced to eighteen months, of which not less than twelve months must be taken at a required dental school.

2. Instruction in dental mechanics is recognized from the date of passing in two of the three subjects of the pre-medical examination (chemistry, physics, biology), but the pre-medical examination must be completed before admission to the first examination.

3. The instruction in anatomy and physiology, including special anatomy and physiology, may be signed for thirty weeks, which *may* be consecutive.

4. Where arrangements are impracticable for the ordinary two years' clinical work in dental surgery, during the first of which general medicine, surgery, and pathology are taken, a six-months course of instruction in egneral medicine, surgery, and pathology, followed by eighteen months of clinical work in dental surgery, will be accepted.

5. It will be seen that these relaxations reduce the total curriculum to three and a half years from the date of passing in two subjects of the pre-medical examinations, the six months being taken off the instruction in dental mechanics.

6. In the examinations, candidates will not be expected to work in gold, but in base metal only.

The Museum is closed but the Library will remain open until further notice. The Buckston Browne Dinner will not be held this year. The annual meeting of Fellows and Members will be held on November 16, at 3 p.m., and not 4 p.m. as previously arranged.

Diplomas of Fellowship were granted to Eric Samuel and Robert Clarence Laird.

Diplomas of Membership were granted to Phiroz Burjor Banaji, Robert Douglas Neil Bisset, John David Dudley Boswell, John Cuthbert Herapath, Henry Edwin Hobbs, Frederick Grafton Lougee, Simon Meleck, Puzhankara Ananakumara Menon, Frank Bradbury Norrish, John Ffrangçon Roberts, Allan Robert Frederick Thompson, Michael Milnes Walker, John Fisher Williams.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH

At a meeting of the Royal College of Surgeons of Edinburgh held on October 17, with Mr. W. J. Stuart, President, in the chair, the following, having passed the requisite examinations, were admitted Fellows:

H. Ahmed, D. I. Adler, Y. N. Ajinkya, G. M. Arnott, H. A. Bali, S. P. Barnett, D. Barton, J. E. M. Cairncross, C. F. Chapple, H. M. Coleman, W. M. Couper, J. F. Curr, G. H. Darke, G. S. Dhillon, N. N. Dravid, A. S. Duncan, J. T. Farr, H. L. Fuller, F. W. Grauer, J. H. Hofmeyr, I. Karro, J. A. Kersley, A. A. Khan, G. D. Killawala, J. A. Kilpatrick, D. H. Lees, A. Lutton, J. Macaskill, J. K. McCollum, W. McKechnie, C. M. Marsden, G. D. Matthew, R. Mundy, D. F. O'Brien, A. Orlek, J. H. Pierre, D. A. Reid, J. W. R. Rennie, R. Roaf, H. G. Roberts, Juliet M. De Sa, J. A. L. Scott, G. C. Sen, F. D. Smith, E. Somasekhar, A. Trottier, F. R. Tucker, J. R. A. White, L. J. Wigston, J. D. Wilson.

At the annual meeting of the Royal College of Surgeons of Edinburgh, held on October 18, the following officers were elected for the ensuing year:

President, Dr. H. M. Traquair. *Vice-President*, Mr. W. J. Stuart. *Secretary and Treasurer and Conservator of Museum*, Mr. J. W. Struthers. *Representative on the General Medical Council*, Mr. Alex. Miles. *Convener of Museum Committee*, Mr. W. Quarry Wood. *Librarian*, Mr. J. J. M. Shaw.

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

The customary seasonal increase in the incidence of scarlet fever, diphtheria, and pneumonia (primary and influenzal) in England and Wales during the autumn has been observed during the week, but the numbers notified are well below the level of the corresponding week in 1938. The effect of the abnormal distribution of an appreciable proportion of susceptible subjects would appear on the whole to be a favourable one from the epidemiological standpoint, although it is too early to ascribe the lowered incidence solely to this factor. In Eire and Northern Ireland, where there has been no such movement of children, diphtheria has remained below and scarlet fever in excess of the figures recorded last year. To a lesser degree the same holds true for Scotland. The effect of the evacuation of large numbers of children in England is exemplified by comparison of the number of notifications of scarlet fever, diphtheria, and pneumonia in the four largest cities during the present week and the corresponding week last year, the figures for which are given in parentheses:

	Scarlet Fever	Diphtheria	Pneumonia
London ..	32 (180)	25 (125)	24 (47)
Manchester	12 (33)	12 (17)	3 (20)
Birmingham	18 (31)	22 (36)	11 (27)
Liverpool	23 (35)	29 (16)	9 (15)

It is seen that while the decreases for these diseases in England and Wales vary from some 10 to 25 per cent., notifications in these cities have fallen in some instances to a fraction of their value last year—for example, scarlet fever in London fell to one-sixth. The pneumonia figures are naturally less affected as adults are attacked more frequently than children; the observed reduction in the incidence of pneumonia may be due in part to climatic factors, to which, to some extent, may be attributed the general fall in scarlet fever and diphtheria. Dysentery is also below last year's level, although it has increased somewhat recently, the notifications for the last three weeks being 22, 23, 37. Notifications were received from twelve counties, and only one town or district in each county was affected. More than 3 notifications were recorded in Orpington (Kent) 9, Warrington (Lancaster) 6, Amersham (Bucks) 4, Colchester (Essex), Devizes (Wilts), and Bristol (Gloucester) 3 each.

Acute Poliomyelitis

The distractions of war have perhaps in part diverted attention from the fact that poliomyelitis has reappeared in the form of outbreaks, although the weekly notifications for the whole country have at no period reached the 1938 level. In the last four weeks notifications for England and Wales were 29, 38, 43, 42 (present week), compared with 76, 60, 56, 65, in the corresponding weeks of last year. The sporadic and widely distributed character of the disease is illustrated by the fact that twenty counties are at present affected, giving a weekly average of 2 per county. Essex, which was severely hit last year, has practically escaped, while the adjacent county of Kent, across the River Thames, has produced the largest number of cases so far, urban and rural areas being equally involved. Counties reporting more than two cases were Kent 9 (Herne Bay 2, Dover urban, Dover rural, Gillingham, Maidstone urban, Maidstone rural, Whitstable, Queenborough, 1 each); Lancaster 5 (St. Helens 2, Blackburn, Bolton, Littleborough, 1 each); Middlesex 5 (Willesden 2, Harrow 1, Ruislip and Northwood 1, Yiewsley and West Drayton 1); Warwick 3 (Birmingham, Rugby urban, and Coventry, 1 each).

Dysentery in Europe

Notification of dysentery is in force in all European countries with the exception of Portugal and Albania, but the accuracy of the data varies greatly in different countries and even in different areas of the same country, according to the facilities for diagnosis and collection of records. The distinction made in notification between the bacillary and amoebic forms of the disease is only enforced in Holland, Italy, Rumania, and Turkey. The Balkans are chiefly affected, and generally speaking the bacillary form is predominant. As in respect of enteric infections generally, dysentery has its maximum prevalence in the late summer and autumn months. In 1938 the maximum was reached in August and September in Germany and Hungary, in August in Rumania, Czecho-Slovakia, and Yugoslavia, and in October in Poland. In Germany the yearly numbers reported have varied from 2,525 with 122 deaths in 1933, to 7,545 with 181 deaths in 1937, while in 1938 there were 5,255 cases and 161 deaths. The character of the disease has apparently become less virulent, although in some other countries the reverse has been observed. In Hungary, for instance, the disease has become both more prevalent and more fatal; there were 1,385 cases with 260 deaths in 1933, and 6,441 cases with 717 deaths in 1938. The situation has been even worse in Poland and Rumania, in which countries there were 6,398 cases with 703 deaths and 6,459 cases with 1,182 deaths, respectively, in 1938. In Czecho-Slovakia and Yugoslavia there have been considerable fluctuations in the last few years; in the former notification fell from 3,059 cases (334 deaths) in 1937 to 639 cases (67 deaths) in 1938; in Yugoslavia the corresponding figures were 2,358 (148 deaths) and 1,278 (104 deaths).

Blood Alcohol.—In a comprehensive paper McGrath describes fully the method of estimation of blood alcohol, the various factors which may influence the concentration of alcohol in the blood, and the medico-legal aspects of the test. The test does not supply an automatic answer to the question "Was the individual drunk?" but may indicate, almost with certainty, that a person was sober at the time of taking the blood sample.—Method and Significance of Blood Alcohol Estimations. J. McGrath.—*Irish J. med. Sci.*, July, 1939, 6, 304.

No. 40

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended October 7, 1939.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1939					1938 (Corresponding Week)

† Death from puerperal sepsis

Medical Notes in Parliament

Business in the House of Commons this week included discussion of British relations with India and progress with the Prices of Goods Bill.

There has been presented to the House of Commons a copy of an international agreement revising the Agreement of 1906 respecting the unification of pharmacopoeial formulae for potent drugs. The revised agreement was signed at Brussels in August, 1929, and His Majesty's Government in the United Kingdom acceded to it on August 1, 1939.

More Hospital Beds in Scotland

Mr. COLVILLE, answering Sir Charles MacAndrew on October 18, announced arrangements under which additional hospital facilities provided under the Emergency Casualty Hospitals Scheme in various parts of Scotland would be available up to the limit of their capacity not only for civilian war casualties but also for ordinary sick persons in those areas who were in urgent need of hospital treatment which could not be obtained elsewhere. The additional hospital beds under the scheme would come into commission in increasing numbers in the near future.

Local authorities and other hospital authorities would be informed as these additional beds became available in areas suitable for their purposes, and full instructions would be given as to the procedure for the admission of patients and for the recovery of the cost of treatment in suitable cases.

Thefts of Drugs from Cars

Mr. ALFRED EDWARDS asked Sir John Anderson on October 19 if, in view of the many cases of dangerous drugs stolen from the cars of medical practitioners, he would take steps to ensure that such persons were penalized for their neglect. Sir JOHN ANDERSON replied that it was important that special care should be taken as regards the custody of drugs, but he knew of no ground for the suggestion that legislation was required to check carelessness by medical practitioners. The Home Office only heard of fourteen cases in the last twelve months where drugs had been included among articles stolen from cars. In ten of these the drugs were recovered intact.

Dr. HADEN GUEST: Is there any foundation for the suggestion that a large number of these losses has taken place? It seems rather a slur on the medical profession.

Mr. A. EDWARDS asked if Sir John Anderson knew that the B.B.C. frequently had to warn people of these occurrences and against taking the drugs.

Sir John did not reply to these questions.

Welfare Services in War Time

Mr. GEORGE GRIFFITHS asked on October 19 when the ante-natal and the child welfare centres and the tuberculosis dispensaries of local authorities would resume their normal activities. Dr. ELLIOT answered that local authorities generally were using their best endeavours to remedy such disturbances as had been caused by war conditions in these services. His policy was to encourage this process to the utmost. The extent of the service required in any particular area might have been increased or decreased as the result of changes in the distribution of the population, so it was scarcely possible to say when a condition which could be described as normal would be reached in all areas.

On October 24 Mr. D. ADAMS asked the Minister of Health whether he would take steps to ascertain whether attendances at child welfare clinics were being maintained. Miss HORSBRUGH replied that welfare authorities generally were doing their best to maintain these services, and the Ministry's regional medical staff were asked to keep the position in different localities under review. It was desirable in present circumstances to keep down specific requests for information from the Ministry to local authorities as far as possible. Miss Horsbrugh also assured Mr. D. Adams that, in weighing the needs of the nation in financial and other respects, the Government would attach full importance to the adequate maintenance of the health services, which they recognized as a necessary part of the nation's requirement in war as well as in peace.

Personnel of Medical Boards

On October 19 Mr. T. GROVES asked why in Surrey two medical men received £1,000 per year for examination of recruits for the Forces, whereas in the same area other available doctors were denied the opportunity of acting for such boards. Mr. ERNEST BROWN answered that there were five medical boards in Surrey, members of which were drawn from panels consisting in all of over seventy practitioners. He did not think any increase in this number necessary. Payment was made not at a fixed annual rate but by fees according to the number of sessions attended. He would inquire into the distribution of the work among the members of the panels, but was not aware of any dissatisfaction in this matter. Nor was he aware of any general dissatisfaction among members of the medical profession with the personnel of medical boards. He received representations last August from the Medical Practitioners' Union with regard to the method of selecting this personnel. He was not satisfied that any change was necessary.

Tuberculosis Services in Wales

Dr. ELLIOT told Mr. James Griffiths on October 19 that action on the Report on Anti-tuberculosis Services in Wales had unfortunately been interrupted by the war. He could not say how soon it would be possible, in the new circumstances, for the authorities concerned to complete their consideration of the matters involved. Hutted hospitals in Denbigh and at Chepstow were being proceeded with. These would be of assistance, subject to the requirements of the casualty service, in connexion with tuberculous patients.

Payment of Doctors in Reception Areas

Dr. ELLIOT said on October 19 that he was not aware that medical men in certain areas to which children had been evacuated were informed that payment could not be made out of the funds provided for the medical attendance and treatment of these children unless such medical men had joined the scheme for the protection of practices instituted by a voluntary organization of medical men. He had not sanctioned such procedure. He had received a complaint that the condition was being imposed in one area, but had ascertained on inquiry that this complaint was without foundation.

Second Evacuation of School Children

The supplementary scheme of evacuation, which is confined to unaccompanied school children, has been carried out in several areas, and will be completed in all the evacuating areas in the next two or three weeks. Dr. Elliot has given orders that evacuating authorities shall carry out medical inspection and, if necessary, treatment of all children in the parties.

In a reply on October 19 to Mr. McEntee, Dr. ELLIOT announced that about 11,000 expectant mothers and 445,000 mothers and young children were evacuated at the outbreak of war. He now awaited a return from local authorities of the numbers who still remained in the reception areas.

Compensation for Civilian War Injury

In the House of Commons on October 24 Mrs. ADAMSON moved for an address to the King asking for the annulment of the Personal Injuries (Civilian) Scheme, 1939. She said that the scheme was not wide enough. She objected to the provisions affecting women and children, particularly in regard to injuries and pensions allowances for wives. Dr. EDITH SUMMERSKILL, in seconding the motion, said that in fixing the children's allowances the Government was advised by men who were scientifically out of date and were thinking in terms of nineteenth century medical science.

Sir **Francis Fremantle** said that Dr. Summerskill was wrong in saying that the Government was receiving out-of-date medical advice. She ought to know that the Medical Research Council was as up to date and as progressive as any body of beings could be in this country. Dr. Summerskill, interposing, said she had not attacked the Medical Research Council. Sir Francis Fremantle said that to meet all the criticisms which had been made during the debate would cost the country tens of millions of pounds. He agreed, however, with the criticism of the limitation imposed on the number of children to be provided for.

Sir **Walter Womersley**, replying to the debate, said that the scheme was an essential part of the general arrangements for the relief of war distress. In fixing these terms their decision had to be governed by the over-riding consideration that the resources of the Government for compensation for injury to persons were not unlimited. The scheme of compensation for war injury was not the last word, and when the war was over he believed that the House would insist on a review of the whole position. The Government had clearly laid down the principle that there could be no inherent right in the general population for compensation for the fact of injury, and that any liability accepted by the State towards those injured in the performance of public service must be in respect of actual loss resulting from injury. It was reasonable to limit compensation in respect of injury to persons not gainfully occupied to cases in which family circumstances gave evidence of actual need. An interdepartmental committee was inquiring into the anomalies with regard to children's allowances, and he hoped that a report would soon be forthcoming.

The motion for an address was negatived by 137 votes to 113, a Government majority of 24.

Hospital Treatment of Civilian Population

Dr. **Elliot**, replying to Mr. D. Adams on October 24, said that the accommodation in existing hospitals in England and Wales had been increased by the introduction of 100,000 additional beds, together with the necessary equipment; and arrangements had been made to provide the medical and nursing staff required for these beds. Beds were at present available in the hospitals of this country for all civilians in need of in-patient treatment. The building of huts to accommodate 38,000 further beds was well advanced, and some of these huts were already completed and equipped for immediate use. Every effort was being made to accelerate the completion of the remainder. It was his desire and intention that the necessity for providing hospital accommodation for members of the Forces should not prevent treatment being given to civilians whose health was in danger, and he trusted that the local hospital authorities, especially in areas such as Tyneside, where long waiting lists existed before the war, would make every possible use of the additional accommodation which was at present being provided in their areas.

Institutional Treatment of Tuberculous Persons

On October 24 Dr. **Elliot**, replying to Mr. Parker, said there was no question of the treatment of tuberculosis being at a standstill. While it had been necessary for such tuberculosis institutions as were included in the Emergency Hospital Scheme to keep a certain number of beds available for casualties, any consumptive requiring institutional treatment ought to be receiving it. Letters were now being sent to a number of these institutions releasing them for the present from any obligation to keep even a percentage of beds available under the Emergency Scheme, and these institutions would therefore be able to take in patients exactly as in normal times. Any discharged persons suffering from tuberculosis who would benefit by further treatment in an institution or who would act as sources of infection in their homes should at once be readmitted. The care and attention of tuberculous persons living at home was not at any time a normal function of a sanatorium except at a few special institutions, but was undertaken by the family medical attendant and the tuberculosis dispensary organization acting in co-operation.

Medical News

The Library of the British Medical Association will be open from 9.0 a.m. to 5.0 p.m. (1.0 p.m. Saturday) until further notice.

In view of the coming dark days the out-patient department of the National Hospital for Diseases of the Nervous System (Queen Square, W.C.) will, from October 30, be open daily at 9.30 a.m., except on Saturdays.

The annual public meeting of the Save the Children Fund, which was to have been held on October 28, with the Chinese Ambassador as principal speaker, has been abandoned owing to war conditions.

Owing to the outbreak of war it has been found necessary to cancel the members' meetings of the Eugenics Society arranged for November 21 and December 15. It is hoped to be able to resume the meetings in the early spring.

Unless cancelled by reason of the war, the next congress of the International Association of Women Doctors will be held at Budapest in 1940, when the following subjects will be discussed: (1) the hygiene of school children from the point of view of nutrition, school work, physical culture, and sleep; (2) the principles, methods, and results of anti-venereal legislation.

Before the outbreak of war arrangements were being made for the third All-India Obstetric and Gynaecological Congress to be held in Calcutta in December next. The subjects chosen for discussion were: (1) anaemia of pregnancy; (2) functional uterine haemorrhage; and (3) maternity and child welfare. Further information can be obtained from the secretary, Dr. S. Mitra, 3, Chowringhee Terrace, Calcutta.

The newspapers record that for the fourth time in thirty-six hours Dr. F. J. S. Hall of Deal went out in the Walmer lifeboat last week in a Channel gale in answer to S O S calls for medical aid from vessels anchored off Deal.

The Swiss League against Cancer will hold its annual meeting at Coira, Grisons, on November 25 and 26.

The *Gazette des Hôpitaux* states that the American hospital at Neuilly, Paris, has offered 500 beds for the French wounded and 1,500 more at its annexe at Etretat.

The issue of *Le Journal Médical Français* for July is devoted to the clinical, demographic, and social study of criminal abortion, and the issue of *Le Bulletin Médical* for August 26 to neuropsychiatry.

At the third International Congress of Neurology held at Copenhagen from August 21 to 25, which was attended by about 500 neurologists from all countries, it was decided that the next congress should be held in Paris in 1942 or 1943.

Owing to the absorption of psychological personnel by official emergency organizations for the treatment of mental casualties, a need has arisen to provide psychological guidance and treatment for those who, although not direct casualties, are suffering from nervous crises owing to war conditions. To meet this need the London Clinic of Psycho-Analysis (96, Gloucester Place, W.1) has organized a temporary psychological aid centre to be opened on Friday, November 3. Three units have been arranged for the purpose of providing advisory consultations and short emergency treatments on Mondays at 2 p.m., Wednesdays at 3 p.m., and Fridays at 2 p.m. The ordinary psycho-analytical routine of the clinic will not be affected by this auxiliary service. Analytical treatments will be carried on as before, and analytical consultations will be given at the usual time—namely, each Tuesday at 5 p.m. If necessary emergency treatments will also be provided on this day. In addition to the treatment of psychoneurotic crises, each unit will be ready to deal with disturbances of character and to advise on various psychological problems arising out of emergency conditions.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS.—All communications should be addressed to the Advertisement Manager (office hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are
EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*
SECRETARY, *Medisecra Westcent, London.*

The address of the B.M.A. Scottish Office is 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh;* telephone 24361 Edinburgh), and of the Office of the Cumann Dochtúirí na h-Éireann (I.M.A. and B.M.A.), 95, Merrion Square, W., Dublin (telephone 62550 Dublin).

QUERIES AND ANSWERS

Testosterone for Enlarged Prostate

Dr. C. HORWITZ (London, N.1) writes: I have a case of slightly enlarged prostate in a man aged 53 years. I would like to hear the experiences of any of your readers with regard to the use of testosterone propionate in such a case.

Fractured Femur in the Field

Dr. W. R. WILSON (Doncaster) writes: During the last war Captain F. B. Chevasse described in your columns a novel way of dealing with fractured femurs in the field (October 5, 1918, p. 373). Can you, please, or any of your readers, say to what extent it was used, and whether it stood the test of experience? The plan was to fasten the foot of the broken limb to the end of the stretcher and then elevate this end with the man on it up to 45 degrees (or more), allowing him to remain so until a convenient opportunity for evacuation. A strap or strong band was passed between the legs and made fast to the head end, tightly enough to maintain the amount of extension that had been achieved by the man's own weight. (Thomas's knee splint is very good, but it may not always be available when a stretcher is.) With sundry other bandaging the man was ready for carrying in the horizontal position.

Sawdust Bags for Wounds

Mr. K. KNOWLES, F.R.C.S.Ed., writes: I am sure many will welcome Mr. Ian Fraser's letter on war hospital supply depots (*Journal*, October 21, p. 829). Bags filled with fine sawdust have for very many years been used in the large C.M.S. Hospital, Srinagar, for discharging wounds. They are easily prepared and sterilized, and are cheap as well as satisfactory.

Income Tax

Refresher Course Expenses

"MEDICUS" has claimed to deduct under Schedule D expenses incurred in a refresher course not directed to the taking of a degree; the inspector of taxes has refused the claim.

⁂ The point has not been the subject of judicial decision, but we understand that the claim made by "Medicus" is allowed generally with the agreement of the Board of Inland Revenue. Where the course is not taken with a view to the obtaining of a degree, or to the expanding, as distinct from the bringing up to date, of the medical knowledge of the practitioner, the expense is analogous to the maintenance of the medical library or equipment and is allowable. We suggest that "Medicus" should ask his local inspector of taxes to submit the point to his headquarters.

Amount of Tax Payable

"CONJOINT" inquires what tax will be payable under the new Budget on a salary of £500 or £450 a year respectively less £102 expenses by a married man with one child.

⁂ The calculation is as follows:

Salary less expenses..		£398
Allowances: Earned Income	£80	
Personal	£180	
Child	£60	
		£320
Tax payable at 2s. 4d. on..		£78
		that is, £9 2s.

Assuming no further change next year than those already provided for, the tax payable for 1940-1 will be £21. On a basis of £450 less £102 expenses the tax payable for this year and next year would be £4 8s. 8d. and £13 2s. 6d. respectively.

LETTERS, NOTES, ETC.

A Students' Register: Correction

THE DEAN OF THE FACULTY OF MEDICINE of Liverpool University writes: May I point out, in reference to an incorrect statement in the *British Medical Journal* for October 21, 1939 (p. 821—article entitled "A Students' Register"), that my predecessor in the Deanship sent to the General Medical Council on November 30, 1938, lists of students of medicine who commenced professional study at the University of Liverpool in 1938.

Evacuation of Women and Children

Dr. ESTHER CARLING writes from Aylesbury: After a month of stocktaking, and hard thinking certain facts seem to emerge. (1) There is no criticism of the central idea that children should be protected; but (2) indiscriminate billeting can only be tolerated as a very temporary emergency measure; (3) the casting forth of mothers and children under 5 has been in the main a failure. Put these facts against the constantly reiterated Government plea that parents in evacuation areas should think again before rejecting the offer of safety. Then consider how the rural end of the problem can be adjusted to the Government's decision. First take the question of loyalties. Is the town mother in a danger zone to put her young children before her home and her husband? Can she wisely forgo the claim of the family as the unit? Had they not better stand or fall together? Must she accept the dictum, "Women and Children first?" That involves the further question, Are women human first or women first? If human theirs is the right to choose, but if their sex differentiation is their main function then they must have priority treatment. Population experts stress the value to the race of its women of child-bearing age, and in this way scientific research bears out the finding, "Women and children first." Doubtless the Government had this in mind in framing its schemes for the evacuation of mothers. The plan has failed not only from the incompatibility of town and country, or the difficulty of adjusting richer to poorer, clean to less clean, etc., but also because of the essential question, "What is my duty, where do I belong?" If country people are asked for a considered opinion they would stress the need for crêches or nursery schools as the solution for the youngest children. Then they will hear of prohibitive cost and will become uncomfortably conscious of their own unoccupied rooms. The value of such rooms has suddenly gone up. We who have them should be prepared to pay for them more highly than we have ever paid; they mean more to us. We have learnt by very uncomfortable contact how the other half of the world lives, and we have seen that the other half appreciates us as little as we appreciate them. Town mothers shot into the country are not grateful, and the rising tide of country resentment matches the objections of the unwilling guests. For the children, then, camps and crêches—cost us what they may. For the mothers let us think again, and at any rate respect their right to decide where and how their duty lies.

Examination by Medical Boards

Dr. J. AICKIN (Ferryhill), in reply to Dr. G. de Swiet's letter in the *Journal* of October 14 (p. 785), writes: If he will give the candidate a drink of cold water and wait a few moments he will have no difficulty in getting a sample. Some manage better if given the test glass and sent to the w.c. What I find to be a much greater difficulty is the number of men with impacted cerumen in one or both ears, making a view of the tympanum impossible. Syringing the ear will help, but it would be better if the candidate had this done by his own doctor before examination.

BRITISH MEDICAL JOURNAL

LONDON SATURDAY NOVEMBER 4 1939

CLOSED INTRAPLEURAL PNEUMOLYSIS

BY

PETER W. EDWARDS, M.B., Ch.B.

AND

ALAN LYNN, M.D.

(From the Cheshire Joint Sanatorium, Market Drayton)

Artificial pneumothorax has been established for a number of years as a therapeutic measure in pulmonary tuberculosis. While there have been many successful results, there have also been many failures, associated for the most part with adhesions preventing the complete collapse of the diseased area of the lung. The operation of internal pneumolysis was devised by Jacobaeus to deal with adhesions of this character.

Between February, 1936, and December, 1937, 235 patients were operated on by one of us (P. W. E.): 260 operations were done on 255 pneumothoraces. The number of pneumothoraces exceeds the number of patients because in twenty patients with bilateral pneumothorax the operation was carried out on both sides. In five cases only was the operation done in two stages, though in four others a second stage was contemplated but not carried out, as thoracoscopy at a later stage showed that the remaining adhesions were completely inoperable.

TABLE I.—*Internal Pneumolysis, February, 1936, to December, 1937*

No. of patients	235	No. of operations, 260 :	
No. of pneumothoraces, 255 :		One-stage unilateral	210
(1) Unilateral	215	One-stage bilateral (20 patients)	40
(2) Bilateral (20 patients) ..	40	Two-stage unilateral (5 „)	10

Clinical Material

Of the patients operated on 50 per cent. were in a far advanced stage of the disease and 42 per cent. were advanced cases. While many of those with very extensive disease had responded to artificial pneumothorax and routine sanatorium treatment, some had failed to show such a response, and internal pneumolysis was carried out in these cases more or less as a last resort.

On admission to the sanatorium the patients were grouped according to the Ministry of Health classification, as follows:

TABLE II.—*Clinical Material (235 Cases)*

	No.	Per cent.
TB minus	16	7
TB + 1	2	1
TB + 2	99	42
TB + 3	118	50

Operative Results

The numbers and percentages given refer to artificial pneumothoraces.

TABLE III.—*Results in 255 Pneumothoraces*

Operative Result	No.	Per cent.
Complete	86	34
Partial	140	55
Inoperable	29	11

Complete : All the adhesions seen during the operation cauterized.
Partial : Some of the main adhesions cauterized wholly or partially.
Inoperable : The main adhesions deemed completely uncauterizable.

Complete division of adhesions was possible in only 34 per cent. Jacobaeus (1923) in his early cases obtained a complete collapse in 75 per cent., Chandler (1937) in 50 per cent., Gullbring (1934) in 73 per cent., and Anderson and Alexander (1937) in 37 per cent. The results reported by Jacobaeus, Chandler, and Gullbring were apparently obtained in cases selected as likely to be suitable for the operation, and show a high percentage of technical successes. On the other hand, Anderson and Alexander operated on 111 cases selected from 627 patients undergoing artificial pneumothorax treatment and obtained complete collapse in only 37 per cent. Alexander believes that less than 25 per cent. of patients undergoing artificial pneumothorax treatment are suitable for internal pneumolysis.

In the present series all patients undergoing artificial pneumothorax treatment were submitted for the operation with the exception of a few (less than 10 per cent.), for whom it would obviously have been futile. The results therefore suggest that complete collapse can be obtained by this method in over 30 per cent. of all cases of artificial pneumothorax. Adhesions were partially divided in 55 per cent. (Anderson and Alexander (1937), 41.4 per cent.) and were completely inoperable in 11 per cent. (Anderson and Alexander, 21.6 per cent.). Comparison of the results in this series of unselected cases with the results obtained by Anderson and Alexander in a selected series suggests that Alexander's estimate that less than 25 per cent. of all cases of artificial pneumothorax are suitable for the operation is much too low.

Radiological Result

The result is classified as "satisfactory" when the diseased area is fully collapsed and when cavities, if present before operation, are closed. "Improved, not satisfactory," indicates an improved but not complete collapse, and cavities, if present before operation, are not closed.

TABLE IV

Radiological Result	No.	Per cent.
Satisfactory	100	39
Improvement not satisfactory	35	14
Unaffected	71	28
Partial Symphysis	25	10
Obliterated	24	9
Total	255	100

X-ray films taken before operation were compared with those taken two weeks after operation and with subsequent films, in most cases six months after operation and in some up to nine and twelve months or longer. The radiological results are therefore based in most cases on a series of films, and not on films taken immediately before and after operation. Films taken immediately after operation were found to be misleading in estimating the degree of collapse, as even in inoperable cases they showed an improvement in the collapse chiefly in those parts of the lung in which there was little or no infiltration. This improvement was temporary. The results reveal that the collapse was improved radiologically in 53 per cent. and that the operation was unsuccessful in 47 per cent. in producing a better collapse.

TABLE V.—*Comparison between the Operative and the Radiological Result*

Operative Result	Radiological Result					
	No.	Satisfactory	Imp. not sat.	Unaffected	Partial Symph.	Oblit.
Complete	86	61 (71%)	12 (14%)	2 (2%)	7 (8%)	4 (5%)
Partial ..	140	39 (28%)	23 (16%)	42 (30%)	18 (13%)	18 (13%)
Inoperable	29	0	0	27 (93%)	0	2 (7%)
Total ..	255	100	35	71	25	24

The successful division of all the adhesions present does not always result in a radiologically satisfactory collapse. After complete division of adhesions, cavities still persisted in 14 per cent., and in 13 per cent. partial or complete obliteration of the pneumothorax followed. In 71 per cent. of pneumothoraces in which all adhesions were divided a radiologically satisfactory result was obtained. Where adhesions were partly divided, radiologically satisfactory results were obtained in 28 per cent., improved but not satisfactory collapse in 16 per cent., and partial or complete obliteration in 26 per cent.; the collapse was unaffected in 30 per cent. In the inoperable group the collapse was unaffected in 93 per cent. and the pneumothorax obliterated in 7 per cent. Partial or complete obliteration of the pneumothorax not infrequently follows the operation (19 per cent.). It is more likely to occur after partial division of adhesions (26 per cent.) than after complete division (13 per cent.).

Comparison is made in Table VI between the radiological result and the position of the principal adhesions remaining after partial cauterization. These adhesions were classified as follows: (1) *Medial subapical:* the apex of the lung below the clavicle with the adhesions to the mediastinum below the clavicle. (2) *Medial apical:* the apex of the lung above the clavicle with adhesions to the medial thoracic wall above the clavicle. (3) *Apical symphysis:* lung adherent to the pleural cupula. (4) *Lateral apical:* adhesions to the lateral thoracic wall above the second rib in the midclavicular line.

TABLE VI.—*Position of the Remaining Adhesions*

Radiological Result	Med. Subap.	Med. Apical	Apical Symph.	Lat. Apical	Others	Total
Satisfactory..	22	10	3	1	3	39
Improvement not satisfactory	0	13	8	2	0	23
Unaffected	0	5	33	1	3	42
Part. symph.	1	4	11	1	1	18
Obliterated	3	7	6	1	1	18
Total	26	39	61	6	8	140

As partial division of adhesions resulted in radiologically satisfactory collapse in 28 per cent. of cases it is of interest to note the position of the adhesions that were left undivided. In all cases in which medial subapical adhesions were left undivided a satisfactory collapse was obtained, except in four, in which partial or complete symphysis occurred. As these adhesions are usually attached to important mediastinal structures, their division is often difficult and dangerous. When difficulties arise in dealing with these adhesions and when the apex of the lung is below the clavicle they may be left undivided without interfering with the efficiency of the pneumothorax.

Satisfactory results were much less frequent when medial apical adhesions were left undivided. Of those in which a satisfactory collapse was obtained five had upper-lobe cavities below the level of the clavicle, and these closed after the division of lateral or lateral apical adhesions. In the remaining five there were no cavities before operation. In cases with cavities below the level of the clavicle the division of lateral or lateral apical adhesions may result in closure of the cavities even in the presence of an inoperable medial apical adhesion. Similarly, in cases in which an apical symphysis was left after operation the few satisfactory results followed the division of lateral or lateral apical adhesions where the cavities were below the level of the clavicle before operation. The division of such adhesions is therefore worth attempting.

TABLE VII.—*The Radiological Result in TB + 2 and TB + 3 Cases*

Classification	No. of A.P.s	Satisfactory		Imp. not sat.		Unaffected		Part. Symph.		Oblit.	
		No.	%	No.	%	No.	%	No.	%	No.	%
TB + 2	94	48	51	12	13	15	16	9	9	10	11
TB + 3	124	42	34	22	18	36	29	14	11	10	8

A satisfactory radiological result was more often obtained in TB + 2 cases (51 per cent.) than in TB + 3 cases (34 per cent.). The operation did not affect the collapse in TB + 2 cases in 16 per cent. and in TB + 3 cases in 29 per cent. Partial and complete symphysis occurred in similar proportions in TB + 2 and TB + 3 cases. As would be expected the more advanced the disease the less successful is the operation in producing satisfactory collapse, though advanced disease (TB + 3) does not contraindicate the operation, as it resulted in a satisfactory collapse in 34 per cent. of cases in this group.

TABLE VIII.—*Comparison between Temperature, before and Temperature after Operation*

Temp before Op.	No. of Ops.	%	Temperature after Operation							
			Transient						Prolonged	
			<99°		<100°		>100°		>100°	
			No.	%	No.	%	No.	%	No.	%
<99°	185	71	42	23	84	45	48	26	11	6
99°–100°	59	23	2	3	22	37	24	41	11	19
>100°	16	6	0	0	2	12	2	12	12	75
Total	260	100	44	17	108	42	74	28	34	13

Most of the operations were performed on patients without pyrexia (71 per cent.), of whom 23 per cent. had no reaction after the operation; transient reactions with pyrexia of less than 100° F. occurred in 45 per cent., and with pyrexia greater than 100° in 26 per cent.; in 6 per cent. prolonged pyrexia followed the operation. In the group with pyrexia between 99° and 100° before operation 3 per cent. were apyrexial, 37 per cent. had transient pyrexia of less than 100°, 41 per cent. had transient pyrexia greater than 100°, and 19 per cent. had prolonged pyrexia after operation. In the group with pyrexia greater than 100° before operation 75 per cent. had prolonged pyrexia greater than 100° after operation, and in most cases a more marked pyrexia than before operation, while in the remainder the temperature began to settle after the operation was performed.

Temperature reactions are more likely to occur and are more likely to be severe in cases with any degree of pyrexia, but as the operation was followed by a reduction in temperature in some of these cases, pyrexia does not contraindicate the operation in patients in urgent need of it.

Complications

TABLE IX.—*Complications (260 Operations)*

	No.	%		No.	%
(1) Perforation of Lung ..	6	2.3	(3) Pleural effusion*:		
(2) Haemorrhage:			(*a*) Transient	20	8.4
(*a*) Severe	1	0.4	(*b*) Persistent (TB −) ..	26	10.9
(*b*) Slight	6	2.3	(*c*) Persistent (TB +) ..	32	13.5
Total	7	2.7	Total	78	32.8

* Omitting twenty-three cases with effusion at time of operation, leaving a total of 237 operations.

Perforation of lung occurred in six cases (2.3 per cent. of operations), in five of which an unsuccessful attempt was made to release a cavity closely attached to the thoracic wall. In the sixth case a complete collapse was obtained after a very extensive cauterization.

Haemorrhage occurred in seven cases (2.7 per cent.). In six it was slight, and was easily controlled with the cautery at low heat. In one case there was an alarming haemorrhage. While working near the apex, blood suddenly covered the lens of the thoracoscope, and several attempts to find the bleeding-point failed. As the patient was becoming collapsed, the cannulae were withdrawn and the head of the bed tilted down. Routine treatment for haemorrhage and shock resulted in recovery, though a temperature reaction lasted many weeks. The pneumothorax was maintained with difficulty, as partial symphysis took place.

Small amounts of fluid in the costo-phrenic angle are common in artificial pneumothorax. A pleural effusion is therefore defined as any quantity of fluid sufficient to cover the diaphragm in the upright position, and all cases with this amount of effusion or more at the time of operation are omitted. Effusions are divided into three classes: (1) transient —those which disappear in a few weeks; (2) persistent (TB −) —those which slowly or rapidly increase and in which tubercle bacilli were never found; (3) persistent (TB +)—as (2), but in which tubercle bacilli were found.

In this series of operations effusions occurred in 32.8 per cent, 8.4 per cent. being transient and 24.4 per cent. persistent. Owing to the lack of a definition of what constitutes an effusion in much of the published work on this subject, it is difficult to compare these figures with those of others. Jacobaeus (1933) in an early series of cases found effusions after operation in 52 per cent., Chandler (1937) in 39 per cent., Anderson and Alexander (1937) in 33.3 per cent., Matson (1935) in 50 per cent., and Brock (1938) in 35.5 per cent. (including 22.5 per cent. classified as "very small amount").

Tuberculous effusions followed the operation in 13.5 per cent. Chandler (1937) had tuberculous empyema in 1.9 per cent., Anderson and Alexander (1937) in 3.6 per cent., and Brock (1928) in 1.4 per cent. of cases. These authors do not state what bacteriological methods were used in examining specimens of fluid for tubercle bacilli. In the present series all specimens were examined by direct film and culture on Loewenstein medium.

TABLE X.—*Comparison between the Radiological Result and the Incidence and Type of Effusion (omitting Inoperable Cases and those with Effusion at Operation)*

Type of Effusion	Radiological Result											
	Operations		Satisfactory		Imp. not satis.		Unaffected		Part. Symph.		Oblit.	
	No.	%	No.	%	No.	%	No.	%	No.	%	No.	%
Nil	137	64	72	52	26	19	31	23	3	2	5	4
Transient ..	19	9	13	68	2	11	1	5	2	11	1	5
Persist. TB − ..	26	12	6	23	2	8	7	27	4	15	7	27
Persist. TB + ..	31	15	4	13	3	10	4	13	14	45	6	19

Transient effusions had apparently little or no adverse effect on the result of the operation. Satisfactory results in the presence of a transient effusion (68 per cent.) were slightly more frequent than in cases in which no effusion occurred (52 per cent.), but with transient effusions partial symphysis was also more frequent (11 per cent.) than in the absence of an effusion (2 per cent.). Persistent effusions had a definitely adverse effect on the result of the operation. Satisfactory results were much less frequent (for TB negative effusions 23 per cent. and for TB positive effusions 13 per cent.), and the increased incidence of partial symphysis and obliteration was striking, being most marked in TB positive effusions. A persistent effusion is therefore a complication that is likely not only to render the operation valueless but may also lead to the obliteration of a pneumothorax, which, though partial, may nevertheless be of use in some cases.

In view of the disastrous effects of persistent effusions on the results of the operation the relation between the incidence and type of effusion and the severity of the disease (as shown by the Ministry of Health classification), the degree of pyrexia at the time of operation, the sedimentation rate before operation, and the extent of tissue cauterized were investigated. The results are shown in Tables XI to XIV.

TABLE XI.—*Incidence and Type of Effusion in TB + 2 and TB + 3 Cases*

Classification	No. of Ops.	Incidence of Effusion		Type of Effusion					
				Transient		Persistent TB −		Persistent TB +	
		No.	%	No.	%	No.	%	No.	%
TB+2 .	84	25	30	10	40	8	32	7	28
TB+3 ..	116	46	40	9	19	15	33	22	48

As would be expected the incidence of effusion is greater in TB + 3 cases than in TB + 2 cases. In addition, in TB + 3 cases persistent effusions are more common and transient effusions less common than in TB + 2 cases. Thus in TB + 3 cases effusions are not only more frequent than in TB + 2 cases, but persistent effusions which have often been shown to lead to partial symphysis or obliteration of the pneumothorax are the most common type to occur in this group of cases.

TABLE XII.—*Comparison between the Temperature before Operation and the Incidence and Type of Effusion after Operation (omitting Cases with Effusion before Operation)*

Temp. before Operation	No. of Ops.	Effusions		Type of Effusion					
				Transient		Persistent TB −		Persistent TB +	
		No.	%	No.	%	No.	%	No.	%
<99° ..	168	47	28	18	38	15	32	14	30
99°–100° ..	55	23	42	2	9	10	43	11	48
>100° ..	14	8	57	0	0	1	12	7	88

In patients without pyrexia at the time of operation not only were effusions less frequent than in those with any degree of pyrexia, but effusions of the persistent type were also less frequent. Even with slight pyrexia effusions were much more common (42 per cent.), and of these over 90 per cent. were persistent. With more marked pyrexia, effusions occurred in almost 60 per cent., and of these 88 per cent. were persistent TB +. It must be remembered, however, that the pyrexial TB + 3 case is the one likely to form an effusion without internal pneumolysis. Consequently, though it is desirable to await a fall in temperature in these cases, careful scrutiny should be maintained lest an effusion form and make internal pneumolysis impossible. A clinical estimate is necessary before performing the operation.

TABLE XIII.—*Comparison between the Sedimentation Rate before Operation and the Incidence and Type of Effusion after Operation (omitting Cases with Effusion before Operation)*

S.R. before Operation	No. of Ops.	Effusions		Type of Effusion					
				Transient		Persistent TB –		Persistent TB +	
		No.	%	No.	%	No.	%	No.	%
Slow ..	73	18	25	10	56	6	33	2	11
Moderate ..	120	38	32	9	24	15	39	14	37
Rapid ..	44	21	48	1	5	5	24	15	71

In patients with slow sedimentation rates at the time of operation effusion occurred in 25 per cent., and of these 56 per cent. were transient and 44 per cent. persistent; whereas, with rapid sedimentation rates, effusions followed cauterization in 48 per cent., of which 95 per cent. were of the persistent type and 71 per cent. were TB positive. As with temperature, delay is desirable before operating if sedimentation is rapid. Only operations urgently necessary should be undertaken in patients with a rapid sedimentation rate—for example, adhesions holding a cavity with evidence of bronchogenic spread in the other lung.

TABLE XIV.—*Comparison between the Extent of Cauterization and the Incidence and Type of Effusion (omitting Cases with Effusion before Operation)*

Extent of Area Cauterized	No. of Ops.	Effusion		Type of Effusion					
				Transient		Persistent TB –		Persistent TB +	
		No.	%	No.	%	No.	%	No.	%
Small ..	36	10	28	5	50	2	20	3	30
Moderate..	127	47	37	13	28	16	34	18	38
Extensive ..	52	21	40	2	10	8	38	11	52

Where only a few small adhesions were cauterized, effusions occurred in 28 per cent., of which 50 per cent. were transient. The incidence of effusions was much the same after moderate and after extensive cauterization, but in the extensive group there is a much greater incidence of persistent effusion of the TB + type.

It is obvious that advanced disease or any degree of pyrexia or a rapid sedimentation rate is associated with a greatly increased tendency to fluid formation, and particularly to tuberculous empyema. In the presence of any or all of them the possible benefits of the operation must be very carefully weighed against the greatly increased possibility of tuberculous effusions, and especially where an extensive cauterization is likely to be needed.

Radiology in estimating Suitability of Adhesions for Cauterization

Experience with the thoracoscope has shown that with the present methods of radiological examination it is impossible accurately to localize adhesions or to estimate their number and extent or their suitability for cauterization. Radiological shadows which suggest cord-like adhesions are often found at thoracoscopy to be sheets of adhesions, many of which may also be hidden by visible adhesions or by the lung, or may be too thin to show on an ordinary film. In this series an attempt was made to estimate the suitability of adhesions for cauterization by examining antero-posterior films taken before operation. Only those cases in which the greater part or the whole of the apex of the lung appeared radiologically to be directly adherent to the thoracic wall were considered inoperable. The figures given show the result of attempting to cauterize adhesions which, on radiological evidence, appeared to be inoperable owing to the presence of an extensive apical symphysis.

TABLE XV.—*Operative and Radiological Results in Cases with an Apical Symphysis Radiologically before Operation*

Radiological Result	Operative Result				
	Complete	Partial	Inoperable	Total	
				No.	%
Satisfactory	Nil	2	0	2	4
Improvement not satisfactory..	Nil	3	0	3	7
Unaffected	Nil	14	16	30	65
Partial symphysis	Nil	4	0	4	9
Obliterated	Nil	6	1	7	15
Total	Nil	29 (63%)	17 (37%)	46	100

In every case the radiological diagnosis of an apical symphysis was confirmed at operation. It was not possible in any of the cases to free the apex completely. Satisfactory results were obtained in only two instances. In these there were cavities in the middle third of the lung; they were collapsed after division of adhesions to the thoracic wall above the level of the cavities. In three cases there was some improvement of the collapse with diminution in the size of the cavity following division of the outer part of the symphysis.

In many cases the area of lung closely adherent to the thoracic wall at the apex was found at operation to be much greater than it appeared to be radiologically. In several instances there was a symphysis from apex to base posteriorly, though radiologically the symphysis seemed to be confined to the apex. In every case in which the cavity was situated close to the apex the operation had no appreciable effect, even when lateral apical adhesions were successfully divided.

Discussion

Here are reported the results of internal pneumolysis in an unselected series of cases of pulmonary tuberculosis undergoing treatment by artificial pneumothorax. The indication for the operation was the presence of adhesions over the diseased area of lung, and in most cases these were associated with uncollapsed cavities. The decision as to the suitability of adhesions for cauterization depended on a thorascopic examination, though in a few cases the size and position of the pneumothorax in relation to the diseased area showed that thoracoscopy would be valueless or impossible, and accordingly they were not submitted to the operation. Apart from these few cases there was no selection, and the results show the value of the operation of internal pneumolysis in unselected cases of artificial pneumothorax.

The figures given reveal once again the deplorable fact that 50 per cent. of patients treated by artificial pneumothorax were classified TB + 3, and that even in this unpromising material a satisfactory collapse was obtained in 34 per cent., though the incidence of effusions in this group was much greater than in patients with less advanced disease. In TB + 2 cases a satisfactory collapse resulted in 51 per cent.

All adhesions were completely divided in 34 per cent. of pneumothoraces, and radiological examination of these showed a satisfactory collapse in 71 per cent. Complete cauterization of adhesions, therefore, does not always result in a satisfactory collapse, this being due in some cases to effusion, and in others to thick-walled cavities, which in spite of complete relaxation do not close. In 55 per cent. only partial division of adhesions was possible, and of these 28 per cent. showed a satisfactory collapse radiologically.

After partial cauterization it has been found that the position of the remaining adhesions and their relation to cavities have an influence on the efficiency of the collapse. In some positions adhesions are more likely to interfere with efficient collapse than in others. Where the apex of the lung has dropped below the clavicle, medial subapical adhesions do not prevent the closure of cavities in the upper lobe. These adhesions are usually attached to important structures in the superior mediastinum, and access to them is often difficult; cauterization, too, is dangerous in this area. Such adhesions may be left undivided unless they can be dealt with easily and safely. Medial apical adhesions are important, and should be divided if possible. They may be left, if access is difficult, where a cavity well below the clavicle is held by lateral adhesions that can be cauterized. Edwards and Stevens (1938) found that 42.3 per cent. of cavities uncollapsed by artificial pneumothorax closed after phrenic evulsion, and probably this operation is more effective in the presence of medial apical adhesions than any other type. An apical symphysis is usually inoperable, though parts of such adhesions are sometimes divisible. This, however, does not lead to any obvious improvement in the collapse and may result in the weakening of the walls of an adjacent cavity with perforation of the lung. Cauterization of lateral adhesions in the presence of an apical symphysis has no effect on apical cavities, but may result in closure of cavities below the level of the clavicle.

Apart from effusions there were few complications, though perforation of the lung occurred in 2.3 per cent. In one case (0.4 per cent.) there was a severe intrapleural haemorrhage, and the patient recovered after routine treatment for shock and haemorrhage. Small haemorrhages (2.3 per cent.) were easily controlled by applying the cautery at low heat to the bleeding-point. Varying degrees of surgical emphysema occurred in many cases, and in six it was severe, extending to the neck and abdominal wall. Apart from discomfort to the patient, no ill effects resulted. Mediastinal emphysema was not observed.

Pleural effusion was the most frequent complication, occurring in 32 per cent., excluding cases with effusion at the time of operation. Transient effusions followed the operation in 8 per cent., and persistent effusions in 24 per cent., more than half of which contained tubercle bacilli. Transient effusions had little or no effect on the result of the operation. Persistent effusions, and especially those containing tubercle bacilli, had a definitely adverse effect on the result of the operation, in many cases resulting in partial symphysis or obliteration of the pneumothorax.

In view of the adverse effects of effusions various factors likely to influence the production of effusions were investigated. Effusions, and especially TB + effusions, were much more common in TB + 3 cases. Tuberculous effusions were also more frequent in patients with any degree of pyrexia or a rapid sedimentation rate, or those in whom an extensive cauterization was performed. In dealing with such patients, therefore, the possible advantages of the operation should be carefully weighed against their much greater liability to effusions.

Radiological examination is unreliable in estimating the suitability of adhesions for cauterization; but if there is definite radiological evidence of an apical symphysis with an apical cavity the chances of a successful division of adhesions is extremely remote, and in these cases thoracoscopy is unnecessary. It is advisable, however, to make use of films of higher penetration than is customary in chest radiology, as films of the usual density may show what appears to be an apical symphysis, but which with a film of higher penetration is a series of separate adhesions. In a certain number of cases with upper lobe adhesions stereoscopic films of the upper half of the collapsed side were taken. While these were definitely more reliable than ordinary films in estimating the extent and position of adhesions, they were not accurate enough to warrant their use as a routine.

The age of the pneumothorax at which internal pneumolysis is performed is said by some authorities to influence the incidence of effusion and the success of the operation. In this series of cases the first 121 pneumothoraces were induced from three to nine months before the operation was performed. In this group complete collapse was obtained in 32 per cent., a radiologically satisfactory collapse in 44 per cent., effusions occurred in 37 per cent., and tuberculous effusions in 13.5 per cent. In the remaining cases the pneumothorax was induced eight to ten weeks before operation. Collapse was complete in 34 per cent., radiologically satisfactory in 35 per cent., effusions occurred in 29 per cent., and tuberculous effusions in 13.5 per cent. Operation more than three months after induction resulted in the division of all adhesions in the same percentage of cases as in those in which the operation was performed within three months of induction, but with a greater proportion of satisfactory radiological results. Effusions were more common in the former group, though the proportion of tuberculous effusions was the same in each. As these groups are probably not strictly comparable in other respects, it is doubtful if the slight differences observed in the results of the operation are significant; there is therefore no definite evidence to suggest that the age of the pneumothorax at which internal pneumolysis is performed, within the age limits stated, has any influence on the success of the operation or the incidence of effusions.

It has been suggested by several authors that the length of the operation has some influence on the result and should be limited to one hour. The extent of the area cauterized appears to have some relation to the incidence of effusion, but it seems unlikely that the time factor alone has any definite relation to the incidence of effusions. It is more probable that the amount of tissue destroyed by cauterization, together with the state of the pleura, is of more significance than the duration of the operation. The amount of tissue destroyed by the cautery in a given time may vary greatly in different patients, depending largely on the technical difficulties encountered, and, in addition, second and third sessions add to the risk of complications. The length of the operation is therefore not a safe guide in deciding on the necessity for a second session, and this should depend rather on the state of the pleura, the extent of the area cauterized, and the technical difficulties, together with the clinical condition of the patient and the sedimentation rate, always bearing in mind the added risk of later sessions.

Double Artificial Pneumothorax

In this series of twenty cases thoracoscopy was performed on the one side before attempting the artificial pneumothorax on the other. As many of these patients were acutely ill the reaction was severe. In the last twenty-nine cases of double artificial pneumothorax this fact has been taken into consideration. If a patient is in good or relatively good condition the thoracoscopy is performed on the one side before inducing the other. If, however, there is a very rapid sedimentation rate, high temperature, or other signs of an acute process in cases in which absolute bed rest alone has failed to reduce toxaemia, thoracoscopy has been postponed and the contralateral side induced at once. The main objection to this procedure is that these cases are liable to pleural effusion. Further, in the very acute cases with much destruction of lung, a phrenic evulsion is performed before doing a thoracoscopy, and this has often resulted in lessening the toxaemia.

Phrenic Evulsion and Thoracoscopy

Normally in cases suitable for a phrenic evulsion this is best performed after the thoracoscopy, as patients with a phrenic evulsion occasionally become short of breath during a thoracoscopy. However, in some cases of artificial pneumothorax with numerous adhesions and only a linear collapse, and where it is impossible to introduce a trocar for thoracoscopy, a phrenic evulsion will result in enough relaxation to permit a thoracoscopy with relative ease. Lastly, in cases of marked toxaemia the phrenic operation may be performed before thoracoscopy.

Summary and Conclusions

The results of internal pneumolysis in an unselected group of 235 cases, in 50 per cent. of which the disease was far advanced, are reported, including twenty with bilateral artificial pneumothorax.

Division of all adhesions was possible in 34 per cent. of pneumothoraces operated on, and partial division in 55 per cent.; 11 per cent. were inoperable.

Radiologically satisfactory results were obtained in 39 per cent., 14 per cent. were improved but not satisfactory, 28 per cent. were unaffected, and in 19 per cent. partial or complete symphysis followed the operation.

In the group of 140 pneumothoraces in which only partial division of adhesions was possible, a satisfactory collapse followed the operation in 28 per cent.

Medial subapical adhesions rarely interfere with efficient collapse where the apex of the lung is below the clavicle in the upright position.

Lateral or lateral apical adhesions may be usefully divided in patients with inoperable medial apical adhesions or apical symphysis in the presence of patent cavities below the level of the clavicle.

Satisfactory results were most frequent with limited lesions in apyrexial patients.

Apart from effusions, complications were rare. Following 260 operations, effusions occurred in 32.8 per cent. of operations (8.4 per cent. transient, 10.9 per cent. persistent TB negative, 13.5 per cent. persistent TB positive). Transient effusions did not materially affect the result of the operation. Results were poor where the operation was followed by persistent effusions, particularly those in which tubercle bacilli were present and the incidence of partial or complete obliteration was high.

Effusions were most common in cases with advanced disease, any degree of pyrexia, rapid sedimentation rates, or in cases where extensive cauterization was carried out. Consideration of the first three of these factors is of importance in estimating the probability of effusion following the operation.

The radiological diagnosis of an inoperable apical symphysis in forty-six cases was confirmed by thoracoscopy. Apart from this group, radiological examination was unreliable in determining the position or extent of the adhesions present. Stereoscopic examination was more reliable than fluoroscopy and antero-posterior films, but was not of enough value to warrant routine use.

Facilities for intrapleural pneumolysis are essential for the proper conduct of artificial pneumothorax treatment, and the operation may be of value even in advanced cases.

The place of double artificial pneumothorax and phrenic evulsion in intrapleural pneumolysis is indicated.

LABORATORY METHODS IN THE DIAGNOSIS AND CONTROL OF FEVERS OF THE ENTERIC GROUP*

BY

J. S. K. BOYD, M.B., Ch.B., D.P.H.
Lieutenant-Colonel R.A.M.C.

In a very brief paper such as this it is impossible to do more than touch on a few of the principal points in which progress has been made in diagnosing and controlling fevers of the enteric group. To those who practise at home it may seem that the existing methods of laboratory diagnosis are adequate and satisfactory, but unfortunately in subjects who have been inoculated with typhoid-paratyphoid vaccine—and this includes practically all Europeans living over-seas—the usual serological tests give very equivocal and unreliable results. In the accompanying table the figures for the British and Indian Armies for the last ten years are shown. The cases classified as "enteric group" have been diagnosed on serological or clinical grounds, and there is good reason to believe that a considerable proportion of them are not true enteric group fevers. It is unlikely that there will be any notable increase in the number of cases diagnosed by cultural methods; for, in the Army, blood culture as well as faeces and urine culture is pursued relentlessly. In outbreaks of typhoid or paratyphoid fever, isolations are made from practically 100 per cent. of the cases: the enteric group cases in the table are mainly sporadic cases, in many of which the diagnosis has been made because nothing else seems to apply. It is obvious that a serological test capable of giving reliable positives and negatives would be of the greatest value.

Table showing Incidence of Enteric Group Fevers in the Army in India (British and Indian Troops Combined)

		1928	1929	1930	1931	1932	1933	1934	1935	1936	1937
Typhoid	Cases	227	293	200	176	161	137	105	82	43	42
	Deaths	33	41	21	25	21	26	16	16	5	?
Para A	Cases	45	58	68	64	67	52	53	59	27	25

	Deaths	45	52	32	39	32	37	22	22	8	?

The usual agglutination test made with suspensions of H or flagella antigen, eminently successful in the uninoculated, has now been completely given up in the military laboratories of India, for it has been conclusively shown that, in subjects inoculated with typhoid-paratyphoid vaccine, febrile conditions other than enteric group fevers produce an anamnestic rise of agglutinins not to be distinguished from that given by enteric infection. Routine tests are now being performed with suspensions of O antigen. These are undoubtedly more specific in their indications, being less influenced by the stimulus of non-enteric infections. Unfortunately the response is somewhat sluggish, and with Dreyer's technique many proved cases fail to show a diagnostic rise in agglutinin. Trials are now in progress using the more delicate technique advocated by Felix, and the results obtained to date give reason for hope that more reliable information will be forthcoming from this test.

---

* Read at a joint meeting of the Sections of Services and Tropical Medicine and Public Health at the Annual Meeting of the British Medical Association, Aberdeen, 1939.

The Vi Agglutination Test

The most recent method of serological diagnosis, which applies at present only to typhoid and not to paratyphoid infection, is a test for the presence of agglutinins for the virulence or Vi antigen, first described in detail by Felix. This test has a more complicated technique owing to the instability of the antigen. The original and probably the most delicate method of performing the test is with suspensions of living organisms, but difficulties in standardization and in reading the results make this a method for the expert. An alternative technique has been provided by the discovery of strains of *typhosum* which are devoid of H and O antigen and possess only Vi antigen. Preparations of such strains can be preserved by formalin without losing their properties, and in this way standardized suspensions can be prepared and issued from a central laboratory.

The Vi agglutination test was first used by Felix for the detection of carriers. In fifty-six chronic carriers he found Vi agglutinins present in every case, although in forty-seven the titre was 1 in 20 and under: with few exceptions all controls were negative. I am indebted to my colleague Major H. J. Bensted, *M.C.*, R.A.M.C., for some data, not yet published, on the results of this test carried out at the Enteric Laboratory, Kasauli, India. In the small number of permanent carriers which were investigated, appreciable amounts of Vi antibody were found in every case. In temporary and convalescent carriers, however, approximately half the cases failed to show Vi agglutinins despite the fact that the organisms were readily recovered from the stools. It would therefore appear that this test is likely to be of great assistance in detecting permanent carriers, but cannot be trusted to give a reliable negative in the routine examination of convalescents before discharge from hospital.

More recently Bhatnagar has applied this test to the diagnosis of cases of typhoid fever, and claims to have obtained an easily detected response in inoculated subjects and a less obvious result in uninoculated natives. The Vi agglutinins appear early and disappear quickly. Bensted, in investigating cases of typhoid fever proved by isolation of the organism, found that about 25 per cent. failed to show any Vi agglutinin when examined at short intervals beginning at the seventh day. In a small number of cases serum was obtained between the first and fifth days: in all of these Vi agglutinin was demonstrated in appreciable amounts. It would therefore appear that this test may be of considerable diagnostic value in the early days of the disease, and further investigations along these lines are being carried out.

Typing with the Vi Bacteriophage

In the realm of epidemiology a notable and important advance has recently been made by Craigie in the discovery of bacteriophage which has a specific action on virulent strains of *Bact. typhosum* (Kauffmann's V forms). Craigie has described four serologically different bacteriophages, and of these one, Type II, is of particular importance from the point of view of epidemiology. This phage has the property of becoming conditioned to the particular strain of *Bact. typhosum* on which it is propagated. Thus if it is propagated for some generations on the Rawlings strain it acquires a high titre for this strain, but shows a low titre for another well-known strain, Ty 2. If this same phage is now propagated for some generations on Ty 2 the position is reversed: it develops a high titre for Ty 2 and loses in large measure its power to lyse Rawlings. Extending these observations over a large number of strains, Craigie has differentiated at least thirteen phage-types of *Bact. typhosum*, some common, some rare, for each of which he has prepared a specific bacteriophage. He has also encountered a small number of strains, probably intermediate between virulent and non-virulent forms, which cannot be typed in this way. These he names "imperfect V forms."

Once the different conditioned phages are available it is a simple matter to type any strain of *Bact. typhosum*. To observe the action of the bacteriophage, a loopful of young broth culture of the organisms to be tested is spread with a standard platinum loop over an area the size of a sixpence on an agar plate. When this has dried, a drop of phage, also from the standard loop, is placed without spreading in the centre of this patch and allowed to dry. The plate is then incubated for two hours, stored in the cold room overnight, and reincubated next day. The results will be obvious in from four to six hours, and may show either a complete confluent patch of lysis the size of a drop of phage or varying numbers of small discrete plaques, or absence of any obvious lysis. For test purposes each of the different phages is carefully titrated and diluted to the strength which against its homologous type will just give a confluent patch of lysis. This "critical test dilution" usually lies between strengths of 1 in 100 and 1 in 10,000 of the original phage, and has little or no action on heterologous types—at most it produces an occasional pinhead plaque which need cause no confusion.

To type an unknown strain a series of patches are sown, from a young broth culture, on an agar plate. These are spotted separately with the different type phages, and incubated as described. A disk of lysis is produced by the phage of the type to which the strain belongs. The phages used are phage I (a polyvalent phage not hitherto mentioned, included to confirm that the strain under test contains Vi antigen) and phage II B_2, C, D_2, E_2, F_2, G, H, and J. Phage A is omitted, as *typhosum* Type A is equally susceptible to the action of all phages. Phages B_2, D_2, E_2, and F_2 act equally on Types B_1, D_1, E_1, and F_1 respectively. If the strain being tested is lysed by one of these phages it must be further tested with phage B_1, D_1, E_1, and F_1, as the case may be: these are strictly specific for their homologous types. Imperfect V forms will be lysed by phage I and imperfectly by some of the phage II types. W forms will show no lysis at all.

Accumulating experience goes to show that the phage type of a strain is a permanent character, unaffected by passage through the human being, by artificial passage through laboratory animals, or by artificial culture. Thus the Ty 2 and Rawlings strains, which are in use in various parts of the world, have proved to be Types E and F respectively, wherever tested. The Rawlings strain now used at the Royal Army Medical College has been passed through mice on innumerable occasions, and still remains F; while in outbreaks of typhoid fever the organisms recovered from all cases prove to be alike, and repeated isolations from the same case are also of one type, although occasionally imperfect V forms and W forms may be recovered from a case which also shows V forms of a definite type. This, of course, is a quantitative and not a qualitative difference in antigen.

Applications of the Bacteriophage Test

The applications of this test are manifold. It affords evidence which may either link up on a suspected carrier with an outbreak or may disprove his connexion with it. Thus the strain which caused the Croydon outbreak was Type D. The carrier suspected of having fouled the water supply which spread the infection also harboured an organism of Type D.

Recently the laboratory assistant of a colleague, who is engaged in the preparation of typhoid-paratyphoid vaccine, developed typhoid fever twelve days after he returned from leave. The question of laboratory infection naturally arose. The strains in use in the laboratory were Rawlings and Watson (F), Ty 2 (E), and a strain called Giglioli, which proved to be A. The strain recovered from the attendant was C, thus proving that the infection had not been acquired in the laboratory, but was probably picked up while he was on leave.

A short time ago an outbreak occurred in Birkenhead which was traced to an infected milk supply; but one case, occurring under rather different circumstances, could not be fitted into this picture. The associated cases of the outbreak proved to be caused by Type E. The anomalous case harboured Type D, thus confirming that it was a sporadic case of different origin.

In commenting on Craigie's work an annotation in the *British Medical Journal* (1938, **2**, 1212) suggested that his methods were unlikely to come into common use, presumably in the belief that the test was very intricate. This is far from being the case, and I hope that the remarks I have made and the demonstration I have put out will dispel this idea and will show that the test is simple and the results refreshingly clear-cut.

To summarize, we have in the Vi agglutination test a promising method of detecting permanent carriers, and in Vi bacteriophage an extremely delicate and accurate means of studying certain aspects of the epidemiology of the disease.

The Joint Committee set up under Subsection (1) of Section 4 of the Therapeutic Substances Act, 1925, has made further regulations (Statutory Rules and Orders, 1939, No. 1395). These Therapeutic Substances Amendment Regulations, 1939, come into operation on December 1 next. They require every holder of a licence to manufacture therapeutic substances, who for any purpose engages in the culture or manipulation of pathogenic spore-bearing micro-organisms, to provide separate laboratories and utensils and apparatus for the culture or manipulation of such micro-organisms. These laboratories and appliances are not to be used for the manufacture of any other therapeutic substance. Part I of the attached schedule lays down provisions applicable to tetanus toxoid, and Part II provisions applicable to gas-gangrene antitoxin. Tetanus toxoid is defined as "tetanus toxin (the sterile filtrate from a culture on nutrient broth of *Clostridium tetani*) the specific toxicity of which has been completely removed by the action of chemical substances in such a manner that it retains efficient properties as an immunizing antigen. Its proper name is 'tetanus toxoid.'" Gas-gangrene antitoxin is defined as "the serum, or the antitoxic globulins, separated from the blood of animals which have been immunized against the specific toxin prepared by the growth of *Clostridium histolyticus* in a fluid medium. The proper name of the substance is 'gas-gangrene antitoxin (histolyticus).'"

CANCER: A CONSIDERATION OF CURABILITY AND OF THE ROLE OF RADIOTHERAPY IN TREATMENT*

BY

RALSTON PATERSON, M.D., F.R.C.S., F.F.R.

(From the Christie Hospital and Holt Radium Institute, Manchester)

The main purpose of this paper is to try to analyse the part which radiotherapy is capable of playing in the treatment of malignant disease, and to consider certain of its limitations. The term "radiotherapy" should be used to include both radium and deep x-ray therapy; to obtain maximum efficiency of treatment policy these agents must be in the same hands. In particular I feel that the respective fields of surgery and radiotherapy—and these two between them remain the only available methods of curing cancer—are much better defined than is generally supposed. Analysis of the proper part which each should play is therefore practicable. Certain of the ideas which I propose to lay before you were suggested by study of a most interesting Ministry of Health publication, "Cancer: An Inquiry into the Extent to which Patients receive Treatment," by Sholto Mackenzie.† I shall have occasion to make frequent reference to that report.

The best approach to the main theme of the role of radiotherapy in malignant disease seems to require as preliminary some consideration of the more basic questions of the extent to which malignant disease is normally curable by any means; to what extent it calls for some treatment even though not necessarily curative in intent; and, lastly, the extent to which in spite of all our knowledge and accomplishments of the last twenty-five years cancer is still a hopeless disease. In Mackenzie's report the subject was approached from the completely objective standpoint of finding out the extent to which certain types of cancer were in fact receiving treatment in this country to-day, as assessed from a detailed analysis of all the cancer deaths in a number of sample areas, no account being taken of possible cured cases. It seemed to me, however, that collateral evidence of value could be built up from a rather more subjective point of view by considering how far the various methods and technical facilities at our command have been proved in practice to be effective or otherwise in dealing with each of the known types of malignant disease.

This subjective survey shows that for each disease type the many manifestations of malignancy fall into groups so near those proposed by Mackenzie that I have taken his three groups as a satisfactory index of the present-day state of affairs. These three groups are shown in Tables I, II, and III. It must be noted that the percentages shown on these tables are not results of treatment, but are the percentages of all cases of registered cancer deaths in the sample communities tested which were found to have received treatment. For his analysis Mackenzie took "treatment" to mean treatment of practically any sort, except palliative surgery, undertaken at any hospital or nursing home, and made no attempt to judge of its efficiency.

---

* Paper read to the Section of Surgery at the Annual Meeting of the British Medical Association, Aberdeen, 1939.

† Reports on Public Health and Medical Subjects, No. 89.

TABLE I.—"*Curable*" *Malignant Disease: Percentage treated*

Uterus, body and cervix, and vagina	56%
Skin, including genitalia	64%
Breast	68%
Mouth, tongue, etc., and lip	71%

The lesions in Table I are called the "curable" diseases in that not only has statistical survey shown that these four conditions can be cured in a worthwhile percentage of cases treated, but experience shows that where adequate treatment facilities exist they are being cured in an appreciable percentage of all cases occurring. Even this is using the word "curable" in a very limited sense when we find that such percentage is somewhere in the region of 25 to 30, and Sholto Mackenzie is only willing to call them "the treatable cancers." Later it will be necessary to emphasize that in this group the general curability is associated with such a high cure rate in the early stages that these four diseases in such early stages can genuinely be called curable even by the standards of other diseases.

The striking fact about these lesions is that they are accessible cancers, diagnosable either on sight or by palpation, and that they require no elaborate or technical means of diagnosis.

TABLE II.—"*Treatable*" *Malignant Disease: Percentage treated*

Stomach	5%	Bladder	29%
Intestine	8%	Ovary	29%
Prostate	18%	Larynx	39%
Rectum	20%	Miscellaneous	42%

Table II presents a longer series, the common characteristic of which is that permanent cure can only be expected in a small percentage of all cases. They are, however, "treatable" diseases in one of three ways. From the surgical point of view certain of them can be labelled "treatable" in the sense that if fortunate enough to be explored in their really early stages they *can* be successfully cured by surgical excision. From the radiological point of view they are treatable in the same sense that a small fraction of the early cases can be cured. Thirdly, they are treatable by radiological methods in another sense altogether—namely, that the majority of cases call for the use of radiation as a palliative agent. It must be realized that the fraction of the total cases occurring which would be cured would still remain comparatively low even were full use made of all present-day diagnostic facilities. It is indeed somewhat of a shock to realize for the first time the extent to which this is the case for so many common cancers, but no good purpose is served by ostrich tactics. Had I not been following the Mackenzie grouping, there would have been some temptation to place carcinoma of the rectum in the first group because of its 20 to 25 per cent. curability by operation; but, even so, this means but little when four out of five cases are inoperable when first seen. Even this dubiety hardly exists, however, in the other lesions. The subject of carcinoma of the stomach, for instance, an extremely common lesion, was discussed at length at the British Empire Cancer Campaign Informal Congress two years ago, and the outstanding impression left by a frank discussion was that, even considering only treated cases, the long-term survivals in this disease represented a negligible fraction.

TABLE III.—"*Incurable*" *Malignant Diseases: Percentage treated*

Liver	0%	Gall-bladder, etc.	10%
Pancreas	1%	Mediastinum	14%
Lung and bronchus	5%	Oesophagus	21%

Table III lists those lesions in which we can still offer so little that we are forced to admit the label "incurable," and to realize that treatment even from a palliative point of view is largely only of psychological value. Again, if making a list *de novo* one might be tempted to pass carcinoma of the oesophagus and perhaps of the mediastinum upwards into the "treatable" group, with as much right to a place there as other lesions in that group. Apart from that, medicine has still little to offer in any of these fields, as is shown by the very low percentages in which treatment has even been attempted.

With this introduction the extent to which radiotherapy as a method of treatment can be fitted into the general scheme must be examined and its relation to surgical methods considered. It seems easiest to present in tabular form the conclusions which I think may be arrived at by analytical study of the material. For this purpose I should like to submit for consideration a classification of malignant disease in relation to treatability by radiotherapy which I recently drew up.* It is inevitable that a few of the points raised in that paper be mentioned again.

It must be appreciated that such tabular methods do not allow for finer shades of classification and, moreover, that it is only possible to catalogue the state of affairs at the present time, forgetting temporarily the promise that radiotherapy will open up further fields as treatment technique develops.

TABLE IV.—*Radiotherapy Usually Contraindicated; Surgery indicated where Lesions are "Operable"*

Carcinoma of stomach. Carcinoma of colon and intestine. Carcinoma of rectum
The connective-tissue sarcomas—for example, osteogenic sarcoma, fibrosarcoma
Most advanced malignant diseases

Taking the bleakest aspects first, we find in Table IV those lesions in which radiotherapy has been adequately proved to have little or nothing to offer. Several of the lesions listed are treatable surgically in their early stages; others are equally hopeless to surgical approach. The sarcomas, if inoperable, may be palliated temporarily, but the fact that treatment is primarily surgical must never be forgotten. In regard to advanced malignant disease, I feel that it is important for the practitioner and the surgeon to learn to accept the therapist's ruling of "beyond radiation," just as in the surgical field "inoperable" is accepted as a legitimate judgment. Far too often unwillingness to accept such a ruling, mostly in the desire to "get something done—it really does not matter what," means that the patient's few remaining weeks or months are made much more distressing than they might have been had the situation been frankly faced and the best use made of opium, that greatest of Nature's drugs in the last resort.

TABLE V.—*Radiotherapy of Some, but Limited, Value. Usually Palliative—only rarely Curative*

Carcinoma of pharynx and larynx
Carcinoma of bladder (late) and prostate
Carcinoma of oesophagus
Carcinoma and sarcoma of lung and mediastinum
Cerebral tumours

---

* Paterson, Ralston, "Cancer from the Point of View of the Radiotherapist," *Brit. J. Radiol.* (in press).

In Table V are listed those forms of malignant disease where radiotherapy is called for as treatment, but in which its very considerable limitations must also be realized. For the most part surgery is out of the question either because of the site of the growth or because it is so often diagnosed late. In one respect this is an experimental field in that much is being done to-day to try to extend the known though limited curative potentialities of radiation. In another sense it is a field in which, along with later cases of other groups, radiation, though not curative, has much to offer in its genuine palliative value. This palliative function of radiotherapy is something comparatively new in cancer therapy, because surgery by its very nature, except in the rare instances of colostomy and gastrostomy, functions chiefly as a curative device. The palliative aspects of radiotherapy certainly merit consideration quite apart from the question of cure or five-year survival. Such palliation may take the form of prolongation of life for periods of months up to several years. What seems, however, of greater importance is its capacity to relieve the manifold distressing symptoms associated with gradual extension of the malignant process—the arrest of haemorrhage or discharge, the cleaning up of foul and ghastly ulcers, the easing of dyspnoea or dysphagia, and, most important of all, relief of pain in many cases.

TABLE VI.—*Radiotherapy the Treatment of Choice: I, Tumours of High Radiosensitivity*

(i) *Embryonal origin:*
- Seminoma testis
- True embryonal tumour of ovary

(ii) *Primitive tumours of unknown origin:*
- Wilms's tumour of kidney
- Some tumours of thyroid glands
- Some tumours of salivary glands
- Some tumours of nasopharynx and nasal accessory sinuses

(iii) *Reticulo-endothelial origin:*
- Leukaemia
- Hodgkin's disease (lymphadenoma)
- Lymphosarcoma (reticulosarcoma)
- Thymoma
- Ewing's tumour
- Endothelioma (of vascular origin)
- Miscellaneous reticulo-endothelial diseases

The third group I have proposed is one showing those lesions which from the point of view of the radiotherapist seem to be his special field. These fall into two distinct subgroups. The first is an interesting and fascinating series of radiosensitive tumours in which, when first given, *x*-ray therapy seems to work magic. The curative possibilities are real but still not high, and the palliative results are of a very high standard indeed. This group is one in which no clash with surgery can arise, as few, if indeed any, of the lesions are amenable to surgical control alone.

TABLE VII.—*Radiotherapy the Treatment of Choice: II, Tumours of Moderate Sensitivity in Accessible Sites*

Carcinoma of:

Mouth, tongue, and lip
Skin (face and hands)
Cervix uteri
Vagina
Anus
Bladder (if limited)
Maxillary antrum

Table VII is perhaps rather more controversial. It is presented nevertheless in the firm belief that to-day only a minority of surgeons with any real experience of the achievements of radiation in these fields, especially by radium, would deny that this is a fair statement of the facts. Mouth and lip, cervix uteri, skin—at least of face and hands—are now almost universally admitted to be a radiation field. Bladder and anus represent a more personal belief, and are perhaps open to debate. The value of really radical surgery as a second choice in the event of radiation failure must, however, be strongly emphasized in regard to the majority of these lesions.

TABLE VIII.—*Surgical Extirpation and Radiotherapy Both of Value. Often Combined, Surgery Dominant*

Carcinoma of breast
Secondary carcinoma in lymph nodes
Carcinoma of body of uterus
Carcinoma of vulva
Carcinoma of penis and scrotum
Carcinoma of the skin (of trunk and limbs, not face and hands)
Benign giant-cell tumour of bone
Mixed tumour of parotid

Lastly, in Table VIII is a series of lesions to which I have given the subtitle "surgery dominant," to indicate that in my opinion these lesions, if operable, must be so dealt with as the first plan of treatment. If they are inoperable, or if they recur, radiation has much to offer even as a curative agent, and in the later stages it remains of high palliative value. Moreover, even where surgery is used it is at times advisable that radiation be employed in conjunction with it. May I illustrate by considering two examples.

In breast carcinoma, where the case is clearly operable, operation is called for, but such operation has its value enhanced if combined with a radical course of pre- or post-operative irradiation. In contrast, the borderline operable case seems to have a greater chance of recovery if dealt with by irradiation first on an intensive basis, and only amputated if that should fail to produce response.

The common mixed-cell tumour of the parotid, although probably more correctly considered as a benign tumour, is another useful illustration. The well-recognized tendency for this lesion to recur after three or four years seems to be very appreciably checked by combining the excision with a radium implant or with radical post-operative *x*-ray therapy.

The Early Case

In conclusion I would like to refer to one aspect of the application of the recent Parliamentary Cancer Bill which perhaps merits some thought. We have seen that there are four cancer types which we can, even using the word in a very limited sense, call "curable"—namely, breast, mouth, uterus, and skin. While we hope that the proposed extension of therapeutic facilities which will undoubtedly be possible under the Cancer Bill may gradually open up greater prospects in all fields of malignant disease, there can be no doubt that for the present the main harvest will only be reaped in so far as the prognosis is bettered in these four lesions only. To my mind that harvest will be reaped only in part, and that in lesser part, through the provision of adequate treatment facilities. Probably more will depend on how far the schemes of education and propaganda which have been allowed for in the Cancer Bill do in fact bring these four diseases to treatment in their early stages. The salient feature about every one of them is that the diagnosis is easy once the question of possible malignancy is raised at all. The lesion can be *felt* or *seen*. In the first instance, therefore, it would seem to be worth while to concentrate effort very largely on two main and essentially simple items. First, we must try to get the public conscious, not so much of cancer as a whole, but merely that medical advice should be sought quickly for the very limited list of signs and symptoms represented by these diseases. Secondly, we must get the practitioner more conscious of the enormous value of early treatment and the consequent critical necessity, where any doubt exists at all, of obtaining consultant opinion or of taking a section for histological examination. While admitting that the latter suggestion is controversial, I personally feel that much would be achieved by engendering the outlook that for the ulcerated lesion a section is as easy to get as a Wassermann test, and is of infinitely more value. Once such cases are diagnosed in their early stages, treatment becomes so important that they should be looked upon as urgent. Urgent treatment is particularly called for in early carcinoma of the breast.

Considering only the knowledge and the facilities at our disposal at the moment, greater immediate achievements are possible from the use of more simplified methods of education and propaganda for the early treatment of the accessible cancers, and by the organization of treatment facilities, than by any visible promise of accomplishment in the technique of treatment, whether by surgery or by irradiation.

Summary

This is an attempted analysis of the part which radiotherapy is capable of playing in the treatment of malignant disease. A survey is made of the various methods and technical facilities available, and how far they have been proved in practice to be effective or otherwise in treating each of the known types of malignant disease.

A classification of malignant disease in relation to treatability by radium is submitted.

The opinion is expressed that greater immediate achievements are possible from the use of more simplified methods of education and propaganda for the early treatment of accessible cancers, and by the organization of treatment facilities.

THE COMPLICATIONS OF GASTRIC ULCER

DESCRIPTION OF A CASE

BY

J. A. MARTINEZ, Ch.M., F.R.C.S.

Resident Surgical Officer, Walton Hospital, Liverpool

It is unusual for more than two of the direct pathological complications of gastric ulcer to develop in one patient. The following case is of interest in that four complications were observed—namely, perforation, gross haemorrhage, pyloric stenosis, and carcinoma.

Case History

A mechanic aged 36 was first admitted to Walton Hospital, Liverpool, in February, 1936. Five hours previously he had felt a sudden violent pain in the epigastrium, and nausea but no vomiting. He gave no history of previous dyspepsia. On examination the whole of the abdominal wall was almost rigid, and there was pronounced tenderness to the left of the umbilicus. At operation a chronic ulcer was found on the anterior surface of the stomach near the middle of the lesser curvature, with a perforation in the centre. The perforation was repaired and covered with omentum and the abdomen closed with a pelvic drain. Apart from the development of a small patch of consolidation at the base of the left lung, convalescence was uneventful and the patient was discharged with instructions to report in two months' time.

He was admitted again five months later, complaining of epigastric pain after food and vomiting. The symptoms had begun two months after the operation. The fractional test meal showed a high acidity without delay in emptying of the stomach. The radiologist reported distortion of the pyloric antrum; the stomach wall was mobile, and no ulcer was seen; there was no evidence of carcinoma. The patient's condition improved with dietetic treatment, and he refused to undergo an exploratory operation.

One month later he was again admitted with a history of having vomited about two pints of red blood on the previous day. There was marked pallor. The red cell count was 1,625,000 and the haemoglobin content 25 per cent. There were two further haematemeses of about eight ounces each on the next two days, and he passed tarry stools for five days. After this his condition improved steadily. The fractional test meal now showed an abnormally low acidity with some delay in the disappearance of starch. The radiologist reported that there were multiple filling defects at the pyloric end of the stomach with some induration of the wall. A blood transfusion of 500 c.cm. was given. The patient was once more urged to submit to operation, but he again refused, and left hospital.

Admitted for the fourth time seven months later, he presented the appearance of advanced emaciation. He had been vomiting repeatedly for three weeks, and it became apparent during the next few days that very little food was passing through the pylorus. He was treated for ten days with gastric lavage and intravenous and rectal salines until it was possible to explore the abdomen under local anaesthesia. A huge indurated ulcer was found on the anterior wall of the pyloric antrum and some soft enlarged lymph glands in the vicinity. The naked-eye appearance of the ulcer did not suggest malignancy. A posterior gastro-enterostomy was done, but it was noted that a gastrectomy would have been better treatment had the patient's general condition allowed it. After this he gained weight steadily and was fairly well on discharge from hospital.

Fifteen months after the second operation he returned, complaining of vomiting of two weeks' duration. He was now pale and wasted, and a small hard mass was palpable in the epigastrium. A fractional test meal showed the characteristics of advanced carcinoma of the stomach, and the radiologist confirmed the diagnosis. The vomiting continued and a jejunostomy was done under local anaesthesia. The patient died two weeks later, two years and nine months after the first operation.

Necropsy.—A large saucer-shaped cancer was found surrounding the gastro-enterostomy opening, which barely admitted one finger. The growth had blocked the pylorus so that it was difficult to pass even a probe through it. There were no secondary deposits in the liver or in the other usual situations. The site of the cancer corresponded with the ulcer noted at the first and second operations, and presumably originated in it. Microscopical sections showed a columnar-celled cancer.

Discussion

The patient suffered from a gastric ulcer which was complicated successively by perforation, gross haemorrhage, pyloric stenosis, and carcinoma. It is difficult to state at what time the ulcer became malignant, but it is likely that the change had already occurred at the time of the second operation, which was done for pyloric stenosis. A gastrectomy performed three months after repair of the perforation would probably have resulted in a cure, but the patient's consent could not be obtained.

FREQUENCY OF THE COMPLICATIONS OF GASTRIC ULCER

The development of these four complications in one gastric ulcer must be a rare occurrence. Any estimate of the frequency of each of the various complications is affected by the fact that only a fraction of all patients with ulcer attend hospital, and almost all the available figures exclude the large ambulant group whose symptoms are never severe enough to demand hospital treatment.

Perforation.—A review of the literature shows that the estimated incidence of acute perforation among ulcer patients in hospital varies between 4 per cent. (Kruse, 1937) and 19.6 per cent. (Thompson, 1937). Eliason and Ebeling (1929) give 10 per cent., and Brown (1934) 11 per cent.

Haemorrhage.—The frequency of gross haemorrhage is given variously as 18 per cent. (Lahey, 1930), 20 to 25 per cent. (Gordon-Taylor, 1937), 28 per cent. (Kruse, 1937), 30 per cent. (Allen and Benedict, 1933), and 38 per cent. (Goldman, 1936).

Pyloric Stenosis.—The only reference I can find to the incidence of organic pyloric stenosis is that of Kruse, who gives a figure of 20 per cent., but mentions that 51 per cent. of peptic ulcers show some obstructive characteristics. Jordan and Kiefer (1934) report on seventy-nine cases in which a six-hour residue was found in the stomach on radiological examination. Only 11 per cent. of these patients required surgical treatment for relief of the obstruction, and it was assumed that in the remainder the obstruction was transient and due to inflammation, spasm, or oedema.

Carcinoma.—The literature on peptic ulcer abounds with discussions of the frequency with which carcinoma develops on chronic ulcer, and even now that the histological characteristics of ulcer-cancer have been described and generally accepted there is wide variation of opinion. Klein (1938) writes: "Malignant degeneration of chronic gastric ulcer, if it occurs at all, is rare." At the other extreme the astonishing figure of 68 per cent. has been attributed to Wilson and MacCarty, but the latter states (MacCarty, 1927) that it is impossible to determine the correct figure. Dible (1925), in a series of necropsy and operation specimens, estimated an incidence of 1.7 per cent. Gutmann (1935) gives 2 to 4 per cent., and his figures agree with those of Hauser (1926) (3.4 per cent.) and Newcomb (1932) (3.75 per cent.). Stewart's (1926) frequently quoted article gives 6.1 per cent., and from Gömöri's (1933) article a figure of 8.6 per cent. can be calculated. Most pathologists now agree that carcinoma is a rare complication of gastric ulcer, and I believe that this view is held by most surgeons, even if their choice of treatment is influenced by the possibility of malignant degeneration.

I am indebted to Dr. H. H. MacWilliam, medical superintendent of Walton Hospital, for permission to publish this case.

USE OF STORED BLOOD FOR TRANSFUSION

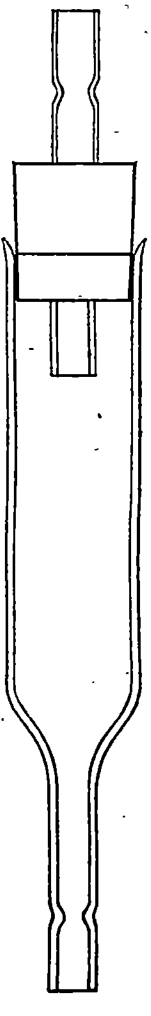
AN INTERIM REPORT

BY

J. L. HAMILTON-PATERSON, M.D.
Pathologist at Redhill County Hospital, Edgware, Middlesex

Group O blood was collected from the voluntary donors of the Emergency Blood Transfusion Service on September 3 and 4, 1939, for use in the event of air raid casualties. As these did not materialize it was decided to use the blood for patients already in hospital and requiring transfusion rather than waste it completely. To keep up the stock, relatives of these patients who belonged to Group O were bled when possible.

The apparatus used was that issued by the Medical Research Council and described in their publication, *Blood Transfusion Outfit*, September, 1939. The anticoagulant employed was pure sodium citrate. This was preferred to the citrate-saline mixture recommended, as in our experience less haemolysis of the stored blood resulted. At the time when the donors for the Emergency Transfusion Service were tested the samples were stored in this citrate-saline mixture (autoclaved in 1-oz. screw-topped bottles) and in many cases haemolysis was practically complete in forty-eight hours. With sodium citrate solution alone treated in the same way this did not occur.



Drip chamber

Method of Storage

Into each bottle 90 ml. (c.cm.) of 3.8 per cent. sodium citrate was put. When blood was added to the 540 ml. mark the final concentration of citrate was 0.63 per cent. The blood was collected straight into the bottle with a needle and a piece of rubber tubing about eight inches long. This was previously lubricated with sterile liquid paraffin. The double-bored cork was not fitted because when the bottle was agitated it disturbed the position of the needle unless a piece of tubing eighteen to twenty-four inches long was used. This was unsatisfactory, as the blood was more likely to clot, and the tubing was much more difficult to clean satisfactorily than the shorter piece. The mouth of the bottle was surrounded by a piece of sterile gauze. Latterly 20 ml. of a 50 per cent. sterile glucose solution has been introduced into the bottle with aseptic precautions. This gives an approximate final concentration of 2 per cent. glucose. The advantages of intravenous glucose in shocked patients is well known, and it also has some value in preventing haemolysis during storage. Spontaneous glycolysis does not occur at the temperature at which the blood is stored, as we have shown by daily sugar estimations over periods of ten days.

The blood was stored in ordinary household refrigerators of the size rented at 2s. 6d. a week, each one of which held thirty-six bottles. The temperature was kept between 2° and 4° C. Two small 3 by 3/8 inch tubes were attached to the side of each bottle with adhesive tape. One contained clotted blood for the Wassermann reaction and the other a suspension of red cells in citrate for cross-matching with the recipient's serum.

When the blood was given, the official administering equipment B was used (glass-bead filter). The beads were added to the blood immediately before use. The only modification introduced was a drip chamber (see Fig.), made from 5/8 by 5 inch pyrex test tubes and glass tubing. This was inserted in the system two inches from the neck of the delivery bottle. If desired the delivery tubing can be filled with saline before puncturing the vein by removing the cork from the drip chamber. During the transfusion it was found that sometimes the weight of the blood in the delivery tube pulled the chamber off the cork. This can easily be prevented by binding the junction with a strip of adhesive tape. Occasionally it was found necessary to cut down on the vein and employ a glass cannula instead of the needle supplied. This whole apparatus has functioned very satisfactorily in practice.

TABLE I

	Date Blood Stored	Date Blood Given	Amount Given	Reaction	Haemoglobin Estimations
1. Male. Bleeding gastric ulcer	2/9/39 2/9/39	5/9/39 8/9/39	540 ml. 540 ml.	No reaction „	5/9/39 40% 7/9/39 32% 14/9/39 40% 30/9/39 69%

Results of the Transfusion

Forty-six bottles of blood have been used. The blood had been stored three to thirty-three days, and the results are shown in Table I. Only in Case 12 was a moderately severe reaction encountered. Within an hour of starting the transfusion the child passed urine coloured a deep red and the temperature rose to 99.6°. On examination no red cells were found in the urine, and spectroscopic examination showed only bands of oxyhaemoglobin. The urine was normal next day and the child had no delayed reaction of any kind. In two cases (Nos. 3 and 4) in which the patients were febrile beforehand the temperature dropped to normal after the transfusion.

Alterations in the appearance of the blood during storage have been noted. The settled red cells turn almost black after three or four days and often a thick white layer of lipoid material settles out on the surface of the plasma. After the first week a layer of haemolysis, pink in colour, appears at the junction of the red cells and plasma. After twenty-eight days this may not be more than one inch deep and still only faintly pink. In some bottles, however, the whole of the supernatant plasma was similarly coloured. After thorough mixing, samples from the bottles were centrifuged. The amount of haemolysis was roughly proportional to the depth of the pink layer in the supernatant plasma, but was of course much more marked after shaking the settled blood. In practice we discarded all the bottles in which two-thirds of the supernatant plasma showed this pink tinge. Usually this pink layer was gelled and separated out in the filter. At no time did the blood show bacterial contamination.

The results of transfusion with stored blood are not so dramatic as with fresh blood. Often there is no immediate change in the patient's condition, and it may be two days before a maximal clinical improvement is noted. Similarly in exsanguinated patients rapid stimulation of blood formation is the exception rather than the rule. Haemoglobin estimations (Haldane) before and after transfusion are shown in Table I.

TABLE II

Length of Storage in Days	No. of Bottles Given	Reaction
3	2	Nil
5	1	Nil
6	3	1 and 2: Rise in temperature 3: Nil
7	5	1: Slight rigor 2, 3, and 4: Nil 5: Nil
8	2	Nil
9	4	1: Slight rigor 2, 3, and 4: Nil
10	1	Nil
11	4	1: Slight rigor 2, 3, and 4: Nil
12	2	Nil
13	4	Nil
16	2	Nil
18	2	1: Slight rise in temperature 2: Nil
19	2	Nil
20	2	Both showed rise in temperature and increased pulse rate
21	4	1: Slight rise in temperature 2, 3, and 4: Nil
22	3	1: Nil 2 and 3: Oxyhaemoglobinuria
26	1	Nil
30	1	Nil
33	1	Nil

Summary

When used for transfusion the blood had been kept for varying times (from three to thirty-three days). No really severe reactions were encountered. In one case there was a transient oxyhaemoglobinuria. In other cases there was a slight rise of temperature and pulse rate, and twice the patients had very mild rigors.

Comparison between the length of storage and reaction produced is shown in Table II. Blood given during the first six days of storage produced no reaction, and thereafter the length of time of storage has no effect in increasing the number of reactions encountered. Dramatic improvement in the clinical condition of the patient is much less frequent than when fresh blood is used. Blood regeneration is also slower.

My thanks are due to the medical officers of Redhill County Hospital for their willing co-operation in giving the transfusions and recording clinical data.

Clinical Memoranda

Paratyphoid B Fever with Respiratory Involvement

Early involvement of the respiratory system in enteric fever has been recognized for many years (Vincent and Muratet, 1917; Osler and Macrae, 1925). These cases give rise to considerable diagnostic difficulties, particularly in the early stages of the disease, the true clinical condition usually becoming apparent when other systemic manifestations of enteric fever appear. The following case of paratyphoid B fever is reported because clinical and radiological evidence of lung involvement remained the most striking feature throughout the whole duration of the illness.

CASE REPORT

A man aged 29 was admitted to a general hospital on October 17, 1938, complaining of headache, generalized pains, and a troublesome cough. At the age of 7 he had had a right empyema thoracis treated by rib resection, since when he had been subject to winter attacks of bronchitis. The present illness was considered to be of this nature until the sixth day after admission, when persistence of an irregular pyrexia and a slight degree of splenic enlargement indicated further investigation. Leucocytosis (58,000) with a slight relative lymphocytosis was present, the blood culture was sterile, but specific agglutinins to *B. paratyphosus* B were present in a serum dilution of 1 in 40 (O) and 1 in 180 (H).

The patient was transferred to the Eastern Hospital on October 26. On admission he was rational but fairly ill, and showed both dyspnoea and orthopnoea. Cough was a very troublesome feature and was accompanied by abundant frothy sputum. There was no impairment of lung resonance, but large rales were present at both bases. Examination otherwise revealed slight tumidity of the abdomen, a palpable splenic edge, and complete absence of abdominal reflexes. The bowels were constipated.

On October 28 the patient complained of pain at the angle of the left scapula, which was aggravated by coughing. Some impairment of resonance was present over this area and was accompanied by a rough pleural friction sound. Radiological examination showed irregular masses of opaque shadows in both lung fields, suggesting pneumonic patches, possibly based on the interlobar fissures. One well-marked area was present in the left lower lobe. The abdomen was now normal in appearance, but the splenic edge could still be palpated. The bowels remained constipated, but paratyphoid B organisms were recovered from the faeces. Blood examination showed a rising titre of specific agglutination to 1 in 80 (O) and 1 in 640 (H).

On November 3 the patient was more toxic and ill. He presented all the features of an acute pneumonic condition with dyspnoea, pleural pain, and a frequent troublesome cough. Sputum was still fairly abundant, but examination on this and other occasions failed to reveal paratyphoid organisms. From this point the patient began to improve. The temperature fell by lysis on the tenth day after admission and subsequent progress was quite uneventful. Radiological examination five weeks after admission showed a complete disappearance of lung shadows.

The resemblance of this type of paratyphoid infection to a purely respiratory disease has already been described by many writers (Stolkind, 1916; Klein and Torrey, 1920; Maxwell, 1937). In the above case the resemblance was so close as to carry a grave risk of delayed recognition, to the danger of other patients in a general hospital ward. The points of clinical value in differential diagnosis would appear to be: toxaemia out of proportion to physical signs in the lungs; splenic enlargement; and absent abdominal reflexes. It has been noted in previous epidemics that a preponderance of respiratory forms has characterized an enteric outbreak, as if the individual strain of organism had a predilection for the respiratory system. Support for this view cannot be gained from the present case, since one of the nursing staff contracted the disease, the illness being of the usual type and quite devoid of any respiratory features.

I am indebted to Dr. N. D. Begg, superintendent of the Eastern Hospital, for permission to publish the details of this case.

A Large Calculus of the Urethra

The following case is, I think, worth recording on account of the comparative rarity of such large stones in this region.

Case History

A man aged 66 was admitted to the Royal Infirmary, Sheffield, on March 25, 1937.

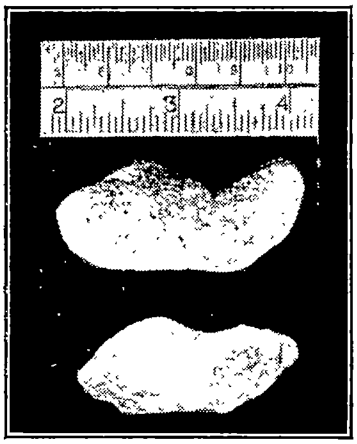
History.—In 1918 while running to a "dug-out" in France he fell on to a piece of wood which struck him in the perineum. There was immediately intense pain at the site of injury and along the penis, and later he noticed a few drops of blood at the end of the urethra. He did not pay any particular notice to this, as there was no difficulty in passing water. He did not report the accident and received no treatment. About three years later he began to suffer from difficulty in passing water. This slowly and progressively became worse, and as time went on he noticed that the stream of urine was becoming gradually thinner. A year before his admission to hospital he found that there was a lump in the perineum. It felt as hard as a bone, and was the size and shape of his thumb. He then found that he was able to alter the character of the stream of his urine by manipulating the lump, and concluded that the thin stream was due to the lump. For a year there had been considerable frequency of micturition. Otherwise he has always had good health.

Examination.—The patient looked well and healthy. On inspection of the perineum a swelling, measuring about 1 by 2 inches, was seen in the middle line immediately behind the scrotum. On palpation it felt hard and almost subcutaneous. It was movable in a transverse direction and was not tender. A diagnosis of a stone in the bulbous urethra was made and was confirmed radiologically. On micturition the stream was seen to be very thin and its character could be altered by manipulation of the stone. Examination of the urine showed pus, the infecting organisms being *B. coli* and a streptococcus. Radiological examination of the rest of the urinary tract did not reveal any other calculus, and the excretion pyelography was normal.

Treatment.—An external urethrotomy was performed and the stone was easily removed from a pouch in the bulbous urethra. The wound was stitched in layers and a soft rubber urethral catheter tied into the bladder. Recovery was uneventful.

Post-operative Course.—The frequency of micturition disappeared gradually during the course of a year. The stream of urine is now normal. The urethra admits a No. 12 catheter, and a urethrograph, taken about nine months after operation, shows the urethral pouch still present but about a third of its original size.

The Stone.—This measured 7/8 inch by 2¼ inches. Its colour was grey and its surface was smooth. On section it was laminated, and in its centre was a pale brown nucleus or primary stone which was also laminated. On chemical analysis the outer and larger portion gave the reactions for calcium and magnesium phosphate and the core or nucleus gave the reaction for calcium oxalate only.



Commentary

It is evident that the patient sustained a traumatic rupture of the urethra in 1918. This was followed by the development of a stricture of the urethra which would have been symptomless but for the fact that it blocked the downward passage of a single primary oxalate stone. The secondary phosphatic deposit on the primary stone seems to have taken place over a period of fifteen years and to have given rise to comparatively few symptoms until the occurrence of acute cystitis.

I am deeply grateful to Professor Ernest Finch for allowing me to treat and publish this case.

T. M. J. d'Offay, F.R.C.S.
The Royal Infirmary, Sheffield.

Reviews

BRITISH ENCYCLOPAEDIA OF MEDICINE

The British Encyclopaedia of Medical Practice, including Medicine, Surgery, Obstetrics, Gynaecology, and Other Special Subjects. Vol. XII, Tetanus to Yellow Fever. Under the general editorship of Sir Humphry Rolleston, Bt., G.C.V.O., K.C.B., M.D. (Pp. 672; index 56; 48 figures; 12 plates, some of which are coloured. 35s. net.) London: Butterworth and Co. 1939.

Volume XII of the new British Encyclopaedia completes the first series. It is to be followed by supplementary volumes containing, first, the index for the whole and certain new information which has come to hand since the first printing, and, secondly, a series of abstracts of medical literature and critical surveys of the development of the special branches. The complete index will be welcome as the present index to each volume is little more than a synopsis of contents. The continuation of the admirable series of articles under the able editorship of Sir Humphry Rolleston and his colleagues will be looked forward to with interest, and it is to be hoped that the war will not lead to a reduction of the high standard of scholarship, accuracy, and production hitherto maintained.

The longest article in the present volume deals with toxicology in its widest aspects. Poisoning, whether for homocidal or suicidal purposes, or accidental, is described by Dr. Roche Lynch of the Home Office, and the subject of industrial poisoning, a branch of medicine of great importance in which already much effective work in prevention has been carried out, by Dr. Donald Hunter. The practitioner will find in these concise and clear descriptions of symptoms and appearances the methods of dealing with such cases in their clinical and medico-legal aspects. The other long contribution is that on diseases and disorders of the uterus; in this four expert gynaecologists deal with its developmental abnormalities, displacements, prolapse, and tumours. One of the most satisfactory sections of the whole encyclopaedia has been that dealing with obstetrics and the diseases of women. The general practitioner has in this series clear and useful instruction in this important branch of his work. In this volume there are in addition sections on affections of the female urethra and on diseases of the vulva and vagina.

The consulting editor in tropical diseases, Sir Leonard Rogers, gives a survey of the incidence of general diseases in tropical countries based mainly on his own data from the analysis of a large number of necropsies on medical cases in Calcutta. It is interesting to note, and these figures are similar to those returned from the Philippines and in tropical America, that only one-third of the total deaths were due to tropical diseases in the strict sense, and even these are predominantly cholera, the dysenteries, and kala-azar. Tuberculosis and respiratory diseases are commoner among tropical patients, circulatory diseases considerably less, than at home. Articles on trypanosomiasis, yellow fever, torulosis, and tropical ulcer are included in this volume. The typhus fevers and trench fever are dealt with by Major-General Sir John Megaw. Both of these are regarded as due to Rickettsia infection carried by human parasites, especially lice, and therefore are liable to occur in widespread epidemics in conditions of overcrowding and defective hygiene, such as may be found during the war. Dr. Izod Bennett gives a useful summary of symptoms and treatment of uraemia, Dr. Dorothy Russell discusses the broad aspects of tumour formation in its effects on the functions of the body, and Dr. L. J. Harris describes present-day knowledge of the vitamins.

ENDOCRINOLOGY

The Endocrine Glands. By Max A. Goldzieher, M.D. (Pp. 916; 271 figures; 42s.) New York and London: D. Appleton-Century Company, 1939.

Professor Max Goldzieher's book on the endocrine glands is the product of thirty years' personal experience. He aims at stressing treatment based on that experience and protests against the nihilistic attitude which has found this startlingly frank expression, " No sound clinician is enthusiastic about therapy."

Large volumes on endocrinology follow one another with such rapidity that a reviewer can best help the prospective reader by calling attention to some individual features in each rather than by an analysis of the contents that would inevitably consist largely of repetition, since in the main they all follow the same plan. In the book before us more attention than usual is paid to the association between the endocrines and the vegetative nervous system, though perhaps greater stress is laid on the clear-cut distinction drawn by Eppinger and Hess between vagotonia and sympathicotonia than is usually current to-day. The importance is emphasized of receptor factors in the tissues in conditioning the response to hormonal stimulation, an aspect of the subject which is steadily attracting increasing attention. The short sections on the part played by endocrines in regeneration, ageing, and rejuvenation contain some interesting suggestions—one can hardly put it higher than that. Among these we may mention the alleged influence of thyroid in facilitating the formation of those areas of regeneration which may occur in cirrhosis of the liver.

Perhaps one of the more novel topics discussed is the influence of the endocrines on the reticulo-endothelial system. It was originally pointed out by Donath and Saxl (1925) that changes in the functional activity in the cells of this system could be observed following the injection of pituitrin or adrenaline. Later observers have claimed that these changes increased the resistance of experimental animals against infection. The author obtained some more direct evidence by injecting dyes, iron salts, and cholesterol, which are stored in the reticulo-endothelial system, and then observing the effects of hormones in increasing or decreasing the amount thus stored. He also employed an endogenous indicator such as bilirubin. As reticulo-endothelial cells are scattered throughout the various tissues and organs of the body they could not act similarly or synchronously unless they were regulated by a superior physiological force. As these cells do not possess nervous connexions they must be dependent upon hormonal influences, which from these observations he concludes are endocrinal. Alterations in the storage of fats and cholesterol in certain pathological conditions he thinks can be explained along similar lines. He attributes a considerable influence in this process to the adrenal cortex, but does not state clearly the evidence on which that opinion is based. We are more favourably impressed with his views on the effect of the pituitary on water storage in the reticulo-endothelial system, for it is clear that in many cases of so-called " pituitary obesity " retention of water plays a large part; salyrgan, which influences the water balance in the tissues, will not infrequently reduce weight more effectively than any organotherapy.

Professor Goldzieher's account of hypothyroid leanness is certainly rather heterodox, and the clinical description of two illustrative cases is not full enough to convince us. It is true, as he says, that pituitary insufficiency may lead on the one hand to obesity and on the other to the atrophy of Simmonds's disease; but the parallel is not really exact, since the pituitary secretes several hormones, while the thyroid only gives rise to one. Loss of weight accompanied by a low basal metabolic rate occurs in various conditions, and the presence of tachycardia in his cases hardly suggests that hypothyroidism was the cause. However, in such a rapidly growing subject as endocrinology there must, and indeed should be, room for different views and opinions. Apart from occasional rather startling statements Professor Goldzieher's book, which is well arranged and well illustrated, will prove a useful work of reference.

ALLERGY

Practice of Allergy. By Warren T. Vaughan, M.D. (Pp. 1082; 338 illus. 50s. net.) London: Henry Kimpton. 1939.

Nominally the third edition of a work by the author, this very large volume is really a new book which differs from its two predecessors in its title and other respects; the issues in 1930 and 1934 of *Allergy and Applied Immunology* were intended for both the medical profession and patients, whereas the present work is addressed to practitioners alone, the patients being provided for in the companion volume *Primer of Allergy*. The whole subject of allergy is exhaustively reviewed: its history, going back to "the father of medicine" and Lucretius, its physiology, aetiology, mechanism and significance, skin testing, elimination diet, percutaneous or diadermal allergy, and serum sickness. These sections form a storehouse of information, and lead up to the last of the sixteen parts of the volume—namely, that dealing with allergic diseases.

In addition to asthma (the term "bronchial asthma" being discarded), hay fever, migraine, skin diseases, and gastro-intestinal disorders, the manifestations, or at least the possible relations to allergy of a number of other diseases, such as thrombo-angiitis obliterans, angina pectoris, arthritis, gout, essential hypertension, and congenital pyloric stenosis, which are not usually included among the group of allergic diseases, are passed in review. Cases justifying this discussion are given—for example, great reduction of high arterial blood pressure as a result of the adoption of a diet free from articles to which the patient was shown to be sensitive. The subjects of thrombo-angiitis obliterans have been found to be sensitive to extract of tobacco in a high proportion. In three cases of angina pectoris, watched for long periods, the author reported considerable improvement, though not cure, by a diet freed from foods to which the patients were sensitive. In the eightieth and last chapter, which lays stress on the need for continuous records of life, a well-deserved tribute is paid to Sir James Mackenzie for the establishment of the St. Andrews Institute for Clinical Research in 1918.

CONSCIOUS ORIENTATION

Conscious Orientation: A Study of Personality Types in relation to Neurosis and Psychosis. By Dr. J. H. van der Hoop. Translated by Laura Hutton, B.A., M.R.C.S., L.R.C.P. (Pp. 352; illustrated. 15s. net.) London: Kegan Paul, Trench, Trubner and Company. 1939.

This book is not for the general reader. The author started as a disciple of Jung and proceeded to an analysis by Freud, and has since sought to discover the common ground between them by an intensive study of their philosophies and methods. He has always been attracted by Jung's attempts to differentiate types, especially the differentiations in relation to conscious orientation—thinking, feeling, intuition, and sensation. After a discussion of the nature and interrelationship of these types he discusses them in reference to the development and outlook of various psychopathic types, particularly in connexion with the psychoneuroses. So far as the psychoses are concerned he correlates his own ideas in typology with Kretchmer's distinction of people into cyclothymics and schizothymics, criticizing Kretchmer as too vague and with too great a tendency to mix pathological with normal manifestations. Finally a philosophical commentary is added, with a concluding chapter on the influence of the personal equation of an author not only on his formulation of types but on his whole approach to psychopathology.

This is not a book which is easily read, but the specialist who can spare the time and give the necessary concentration to the study of Professor van der Hoop's thesis will find himself enriched by the exercise.

DUODENAL DISORDERS

Affections non Ulcéreuses du Duodénum: Duodénites, Diverticules, Stases Mécaniques et Fonctionelles, Tumeurs, Malformations, Parasites. Physiologie Normale et Pathologique, Thérapeutic. By I. Pavel and A. Paunesco-Podeano. Preface by J. Ch. Roux. (Pp. 204; 57 figures; 50 fr.) Paris: Masson et Cie. 1938.

While ulceration of the duodenum is the commonest and most important pathological condition of that organ, there are a number of affections less well known. These have been dealt with simply and yet satisfactorily in the book by Drs. Pavel and Paunesco-Podeano of Bucarest. Just as gastritis has come into clinical prominence again, so duodenitis is now an established condition recognizable by *x* rays. It is, of course, frequently associated with duodenal ulcer, but in many cases there are reticular strial relief pictures of the duodenal mucous membrane with absence of a niche suggestive of ulcer, and an abnormal irritability of the duodenal bulb which is small and shows variable but considerable deformity. As well as this pseudo-ulcerous form, the authors describe duodenitis of haemorrhagic type, usually associated with disease of the gall-bladder or appendix, and duodenitis with jaundice. One of the latter forms is the so-called catarrhal jaundice, but in others there is a chronic state with prolonged jaundice in which at necropsy there is a greater or less degree of hepatitis forming one of the subgroups of Hanot's cirrhosis. Duodenal stasis may be mechanical from scars in the duodenal wall, or pressure from inflammatory processes externally in the gall-bladder region, or from compression by the pedicle of the small bowel mesentery, especially in defective abdominal muscle tone following operation, pregnancy, or illness. Tumours of the duodenum are rare, but parasitic infestation with lamblia and hookworm is fairly often met with. The former may give rise to symptoms in the duodenum and may invade the gall-bladder. Since the perfection of *x*-ray technique the frequency of duodenal diverticula has been reflected in the large number of papers in the medical journals, and while some of these diverticula are without symptoms, others cause patients to have more or less discomfort, vomiting, haematemesis or melaena, while inflammation of the wall of the diverticulum may occur and involve neighbouring organs.

The book is well put together. It begins with a summary of existing knowledge of the physiology of the duodenum, contains a number of useful illustrations and a fairly complete bibliography, and will be well received in a library of reference.

Notes on Books

In *The Restoration of the Peasantries* (C. W. Daniel Company Ltd., 6s.) Dr. G. T. **Wrench** traces the history of the Indian peasantry. His thesis, which was implicit in his earlier work, *The Wheel of Health*, is that the primary function of the land should be to produce food—not profit. He shows how in India, as elsewhere, chemical impoverishment and physical erosion have followed failure to return to the soil everything which has taken life from it and have brought in their train much avoidable poverty and other evils. Dr. Wrench presents many sobering facts and poses several urgent questions. Some of these questions he leaves unanswered, to others his answer is clear: only by the restoration of the peasantries of the world to healthy functioning will a healthy soil be resurrected and maintained and the health of plants, beasts, and man be assured.

Mr. F. A. **Philbrick** has produced a textbook *Inorganic Chemistry* (G. Bell and Sons, 6s.) in which a radical departure is made from the plan of such works hitherto produced. The underlying idea of this departure is the fact that textbooks have hitherto had a tendency to overburden the reader with more or less disconnected chemical facts to the detriment of his grasp of principles. The idea has a sound basis. If, as some may think, Philbrick has only in part accomplished his purpose he has yet done a good work in breaking through tradition; the break is overdue. And if he has carried his principle to too great a length for the elementary student, his book will, none the less, have a value as an additional textbook for supplementary reading which can hardly be overestimated. It is fully informative over a wide range of chemical knowledge.

Applications Médicales du Nouveau Codex et Prescription des Substances Vénéneuses, by Professor **René Hazard** of Paris, gives an account of the changes that have appeared in the French Codex of 1938. These changes are very numerous, because the previous Codex appeared in 1908, and in the intervening thirty years several supplements have been published. The volume also gives an account of the French poison laws, which are based on an Act of 1916, as modified by several subsequent Acts and regulations. These laws bear a general resemblance to those in force in this country. There are separate schedules for poisons, for stupefying drugs, and for drugs which may only be supplied on a medical prescription. The volume provides a brief summary of the essential facts relating to the prescribing of drugs under French law. The publishers are Masson et Cie, and the price 18 fr.

L'Examen du Malade: Guide Clinique de l'Étudiant et du Médecin, by P. Delmas, G. Giraud, E. Jeanbrau, E. Leenhardt, J. Margarot, P. Pagès, V. Riche, L. Rimbaud, J. Terracol, and H. Villard, is published in a revised and enlarged edition by Masson et Cie of Paris at 45 fr. This concise handbook with fifteen chapters but without illustrations describes how to examine patients, including the case history, and covers the wide field of medicine, surgery, obstetrics, gynaecology, neurology, and other special departments. M. Émile Jeanbrau, professor of clinical urology, and eight colleagues of the medical faculty of Montpellier have dedicated this second edition of their combined pens to M. E. Leenhardt, professor of paediatrics, who died while the handbook was in the press. Since the first edition in 1935, not only has the text been revised but two new chapters have been added: psychiatric disorders by Professor Paul Pagès and endocrine manifestations by M. G. Giraud, professor of clinical medicine, who contributes two other important chapters on the general medical examination and most of the laboratory methods. Professor Jeanbrau, with thirty years' experience in teaching, is responsible for the examination of surgical patients and two chapters on examination of the urine—the "living" urine in the clinic and that in the laboratory. Well arranged, this handy volume is provided with a good index.

Preparations and Appliances

A DROP-WRIST SPLINT

Mr. J. S. **Kellett Smith**, F.R.C.S., D.M.R.E. (Cheltenham), writes:

Drop-wrist occurred in some 14 per cent. of cases of injury to peripheral nerves sent for treatment to the electrotherapy and massage department of Summerdown Camp in the four years 1916–20. Splinting was a problem at first. The ordinary small "cock-up" is dirty and uncomfortable in wear, and expensive in the way of plaster and bandages. While in charge of the above department I designed a drop-wrist splint which proved a success in practice. Our own supply was made by an enthusiastic amateur who possessed a suitable workshop, and the pattern was copied afterwards in many other centres. The splint consists of a length of rigid tinned steel wire, gauge 8 or a little heavier, on which is threaded a wooden finger rest and some rubber tubing as padding for the thumb. The wire is then bent to appropriate shape for "rights" and "lefts," and the ends turned forwards to form a pair of loops. A second pair of loops of finer wire is soldered into position as shown. Finally, a piece of inch-wide stout webbing is fixed between the terminal loops. The splint is held in position by two lengths of similar webbing passing through the retaining loops and fastening with book-strap buckles (Figs. 1 and 2).

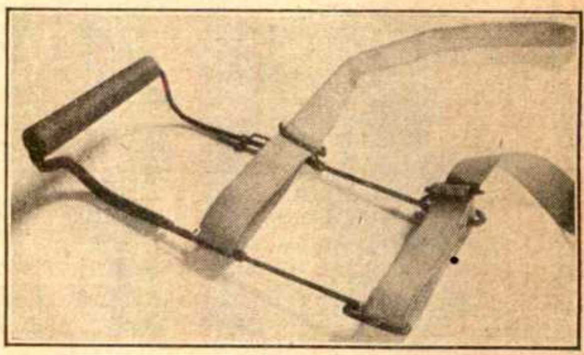


FIG. 1.

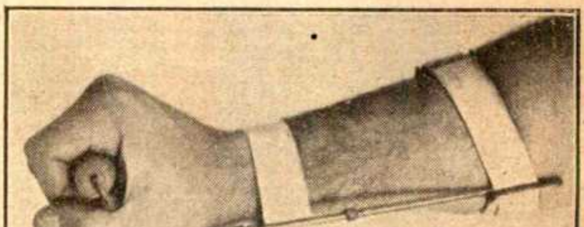

FIG. 2.

The men appreciated the comfort of this splint and made no difficulty about wearing it. It had the additional advantage of costing nothing for bandages.

On October 21 (p. 810) we noticed the polyvalent vitamin concentrate made by H. R. Napp Ltd. under the name "abecedin." In regard to the keeping properties we are asked to say that the warning given by the manufacturers to users of this product as to the possibility of deterioration by air contact after the packet has been opened applies only to the emulsion and not to the tablets, which are sugar-coated.

BRITISH MEDICAL JOURNAL
LONDON
SATURDAY NOVEMBER 4 1939

DRUG TREATMENT OF ANGINA AND HYPERPIESIA

In 1933 Evans and Hoyle[1] showed that drugs were of little help in the continuous treatment of angina pectoris, though they later[2] pointed out that glyceryl trinitrate tablets were of great value in the prevention and treatment of individual attacks, provided they were chewed thoroughly to ensure rapid therapeutic action from immediate absorption of the drug from the mouth. Their conclusion as to the inefficacy of continuous drug treatment in diminishing the frequency or severity of attacks of angina pectoris has been completely confirmed by Master, Jaffe, and Dack.[3] They studied the effect of sixteen drugs, including several xanthine derivatives; alcohol; sedatives such as phenobarbitone, chloral, and bromides; the nitrites; a tissue extract; digitalis; and two narcotics—codeine and dilaudid. No remedy was found to exert any specific effect on the anginal syndrome, for the best effects were obtained with a placebo and the number of patients improved ranged between 15 and 30 per cent. for all drugs. "A new medication, a new physician, a new type of therapy may bring relief. Thus the average patient feels improved during the first few weeks of attendance at the clinic no matter what drug he receives. This probably explains the reports of good results with numerous drugs." A large volume of recent work has proved that the psychological factor is as important in effort angina as in migraine or asthma. It is probable that effort angina occasionally occurs when coronary disease is absent or minimal, and it is certain that effort angina associated with extreme coronary sclerosis may be completely relieved by the removal of emotional stresses such as friction in the home or the work-place and financial insecurity. It is on such factors and not on drugs that the therapeusis of angina pectoris should be concentrated.

Continuing the process of pharmacological deflation, Evans and Loughnan[4] have completed an investigation of the action of thirty-three preparations on the blood pressure and symptoms in seventy patients with hyperpiesia (essential hypertension) over a period of eighteen months. The drugs or preparations were various and included nitrites, iodides, sedatives, xanthine and choline derivatives, vegetable extracts, and hormones. The first important fact which these observations reaffirmed was the great extent of the spontaneous variations in blood pressure. There is commonly an initial fall due to the excitement and novelty of the first estimation, and thereafter quite considerable cyclic variations in the pressure may occur. There seems to be little or no correlation between these fluctuations in the pressure and the symptoms. After allowance had been made for the tendency to obtain high blood-pressure readings at the first and possibly at the second examinations and for the natural variation, and when the results from the tested drugs had been compared with those from a placebo, Evans and Loughnan found that none of the thirty-three preparations produced hypotensive effects in patients with hyperpiesia. In regard to symptomatic improvement only six of the drugs—namely, bismuth subnitrate, iodine and iodide, bromide, sodium luminal, theominal, and potassium thiocyanate—on an average relieved symptoms rather more than did the placebo. The sedative drugs seem to be of use in temporarily relieving nervous symptoms when these are prominent. Reduction of weight in patients with obesity was usually associated with relief of symptoms, but the variations in pressure did not differ from those in the untreated disease.

Whether patients with hypertension would be benefited by a sustained fall in their pressure produced artificially, as it were, and in ignorance of the cause of the condition, is a moot point, for at present there is no medical or surgical means by which this may be done. There are three arguments against the use of drugs in uncomplicated hypertension. First, they are ineffective. Secondly, many are expensive; treatment with padutin can be estimated to cost 5s. 6d. a week, and a three-weeks course of treatment with vagotonine would cost two to four pounds. Thirdly, they may do harm. The only positive effect Evans and Loughnan observed with vagotonine was a severe urticaria. Moreover, a large literature has grown up about thiocyanate therapy in hypertension, which leads to the conclusions that thiocyanates in doses large enough to reduce blood pressure are toxic and may destroy life, and that in some patients there is little or no margin of safety between the toxic and the therapeutically effective dose.[5]

GAS INJURIES TO THE EYE

Fifty-two years ago Leber[6] in a study on inflammation in the eye described the action on the cornea and conjunctiva of a highly irritating chemical compound just discovered by his colleague Viktor Meyer. To Leber, who noted fully the destructive action of this new compound, the point of interest was that it could produce pyogenic inflammation in the absence of micro-organisms, but he lived to see his new laboratory reagent used for less academic purposes. His conclusion that mustard gas could produce a pyogenic reaction was advanced only tentatively, for it was based on a single experiment on a rabbit, and his expressed wish for the experiment to be extended and amplified has since been carried out on a larger scale than he dreamt of and in the grimmest of laboratories. As a footnote to Leber's experiments it may be stated that the German High Command in 1915 fully confirmed his observations on the necrotizing action of this compound, but disproved that it induces a pyogenic reaction in the absence of secondary infection. A conclusion of Viktor Meyer's was also disproved, for it was found that, contrary to his belief, the action of mustard gas was strictly local and not remote from absorption through the blood stream.

[6] *Die Enstehung der Entzündung*, Leipzig, 1891, p. 338.

The fundamental feature of ocular injuries produced by mustard gas is that the injury is directly proportional to the concentration that reaches the eye. During the last war, when vapour gas was used and the methods of distribution were not too effective, only about 10 per cent. of gassed men developed corneal lesions—mostly transient—and it is said that only about fifteen men in all were blinded by gas. The methods of distributing gas that are available to-day are likely to cause more casualties (in the absence of protective measures, which have also grown in effectiveness). The latent period between exposure and the appearance of symptoms, which in the last war was generally six to twelve hours, is thus likely to approach the total absence of a latent period after a splash from liquid gas, and the severity of the reaction is likely to be such that many more cases of corneal involvement, with their much longer course and more serious prognosis, will be seen. In the improved protective measures rather than in improved methods of treatment lies the hope of counteracting these threatening possibilities, for treatment of a gas injury, whether brought about by vapour or by liquid, comes up against the fundamental difficulty that the effect of gas on a tissue is instantaneous, though there is some experimental evidence that the prophylactic use of chlorinating agents will render a gas injury to the eye less serious.[7]

The potentialities of gas warfare have been increased not only by the perfection of the means of distributing more concentrated vapour but also by its possible use in air raids on the civil population. This possibility was usefully discussed in the Section of Ophthalmology at the Aberdeen Meeting of the British Medical Association this year. The discussion revealed that there were considerable gaps in our knowledge of the action of gas on the eye, and that the measures of defence left room for improvement. One of the openers, Colonel A. Irvine-Fortescue,[8] stressed the need for hospital facilities of the marquee type to accommodate a sudden large influx of persons temporarily blinded by gas. It is true that most such patients have no serious lesions, but the irritating symptoms and the anxiety state which develop make in-patient treatment necessary. Patients with no serious lesions, yet unable to open their eyes and afraid of blindness, may well be a source of panic when treated as out-patients. An auxiliary nursing personnel specially trained in eye irrigation and a sufficient supply of irrigators to allow of a considerable number of eye casualties being treated simultaneously are other measures necessary to supplement this improvised in-patient treatment. That such facilities are at present not widely available emphasizes Colonel Irvine-Fortescue's plea for a special civilian ophthalmic corps working under the supervision of an ophthalmologist-in-chief. Besides unresolved administrative problems there were many others of a clinical character, as was brought out by Mr. Arnold Sorsby[9] at the same meeting. Mustard gas being persistent and its action instantaneous, the scope for treatment appears to be distinctly limited. Yet irrigation has some value by minimizing the possibility of a cumulative action. The variety of suggested methods of treatment indicates only too clearly the prevailing confusion. Some would use bland lotions to effect mechanical cleansing; others see virtue in alkaline lotions. Drops of castor oil or paraffin have their advocates, though the wisdom of introducing into the eye substances which act as solvents of mustard gas is doubtful. The weight of opinion is against the use of cocaine or its substitutes to relieve symptoms, as it is generally agreed that cocaine is undesirable because of its devitalizing effect on the corneal epithelium. The employment of atropine in cases of corneal involvement is the one positive feature on which there is agreement. Silver preparations to counteract possible secondary infection, though generally recommended, are condemned by some.[7] The use of ointments as suggested by a correspondent[10] in last week's *Journal* is open to serious objection, while his advocacy of keeping the eyes bandaged is contrary to experience and theoretical considerations. There is indeed nothing to be said for any method of treatment which impedes free secretion of the irritating products of a gas burn and tends to keep the gas pent up in the eye. Bonnefon's[11] recommendation of procedures, such as irrigation by hypertonic lotions, which aim at an increased flow of secretion is physiologically more sound.

The lack of agreement of views extends even to the question of gas-masks. One difficulty is the reduced field of vision induced by eye-pieces in some of the more elaborate masks. The wearing of glasses with most forms of mask is uncomfortable, apart from rendering the masks ineffective from disturbed fitting. Specially made spectacle frames of reduced size and white metal do not overcome the disadvantage of moisture settling on the lenses, for the spectacles tend to disturb any anti-dimming substances applied to the lenses or eye-pieces of the mask. From a careful survey of various possible devices for the individual compelled to wear glasses with his mask, Cot, Moynier, Genaud, and Robert[12] conclude that the best procedure is the incorporation into the gas-mask of two separate wire rims each carrying a lens. This arrangement is easily fitted into the standard gas-mask used in France, but would not appear to be suitable for the corresponding model in this country.

POTASSIUM IN THERAPEUTICS

The clinical scientist, perusing perhaps for the first time that admirable volume the *National Health Insurance Formulary*, may notice with interest the extent to which potassium salts enter into popular therapeutics, and he cannot fail to be surprised to learn that the total amount used medicinally runs into hundreds of tons a year. Much of this is in the form of the bromide and is a relic of the days when the corresponding sodium salt was difficult to prepare in a pure form. Sodium and ammonium bromide have nowadays certain theoretical advantages over the potassium salt and may well replace it if necessary. In other prescriptions potassium salts are used merely for what the pharmacologist calls a salt action, and this is the use which may most seriously be questioned. An average diet contains from 3 to 4 grammes of potash and 5 to 8 grammes of soda a day. Sodium chloride deficiency is quite common, but potassium deficiency appears to be unknown. Anyone who has treated a case of Addison's disease by means of a low potassium diet knows how difficult it is to reduce the intake of potassium. The only conditions in which the action of the potassium ion appears to be of value are the rare nervous diseases familial periodic paralysis[13] and myasthenia gravis.[14] Large doses of potassium salts have also been recommended in asthma and other allergic diseases,[15] [16] but here their value is much more problematical. Until recently the oedema of Bright's disease was an accepted indication for potassium salts, but evidence has now accumulated to show that they may be very dangerous when the kidney is diseased. At the meeting of the Association of Physicians of Great Britain and Ireland last year[17] several speakers described how patients with oedematous nephritis often died suddenly and unexpectedly, and they attributed this to the use of potassium salts as a diuretic, with consequent retention of the depressant potassium ion in the body fluids. Thomson[18] has shown this graphically by serial electrocardiograms in patients with nephritis to whom potassium salts were given in high dosage. There seems little doubt about the risk of sudden cardiac death if the level of potassium in the body fluids rises much above the normal levels. The term "diuretic" is sometimes used in other senses than the relief of dropsy, and potassium salts are prescribed as diuretics and diaphoretics in febrile illnesses. The prescription of saline solutions for such a purpose is not a very rational procedure. A moment's thought shows that the only way to get water out of a dehydrated patient is to put water in, and fluids must be pushed by mouth, by rectum, or in the last resort intravenously, until the tongue becomes moist and the output of urine rises to 1,500 c.cm. a day. Potassium salts are likely to do more harm than good under such conditions, and, if salts must be prescribed, they should be salts of sodium. A febrile urine means no more—and no less—than a failure on the part of the attendants to meet the increased requirement of fluid when the temperature is high. Finally, alkaline potassium salts are given in urinary diseases such as pyelitis, cystitis, and urethritis, but here the action is sedative rather than diuretic and the therapeutic agent is the alkali and not the potassium. There is no reason why sodium citrate should not be used for alkalinization. A pleasant way of administering it is to dissolve three-quarters to one teaspoonful in a nearly full glass of cool water and add slowly the juice of half a large lemon or one lime.[19] We understand there is no actual shortage of potassium salts, but the physician wishing to reduce his drug bill, whether in private or panel practice, might more often pause and ask himself, "Do I really wish to prescribe potassium?"

THE LONDON AMBULANCE SERVICE AND ITS CRITICS

The London ambulance service normally consists of twenty-two stations and 173 vehicles. To this has been added a volunteer ambulance service, formed for the transport of injured persons to first-aid posts and hospitals, which comprises some 200 stations, most of them, of course, buildings designed for quite other uses, an unstated number of vehicles of various sorts, and a staff of about 8,000 volunteers, among whom men and women are in about equal proportions. Although the service is described as "volunteer," the majority of the workers are paid for their services. Various criticisms have been directed against the service; they are not as pointed as those which concern the A.R.P. services in general, but it is complained that the service is not sufficiently co-ordinated with the other precautionary services, that it overlaps in some directions and leaves lacunae in others, and that there is a lack of sufficiently strict central control, leading to a certain absence of discipline in the rank and file. One detailed criticism is that the ambulance stations and the stations of the A.R.P. stretcher parties do not correspond, but as to this it is pointed out that the stretcher party stations are much more numerous than the ambulance stations, and, moreover, that the stretcher parties, after placing their casualty cases in the ambulance, may be called elsewhere to render first aid, so that there is still good reason for keeping the two services separate and under different directions. It is not quite clear how many volunteers have been enlisted for stretcher party work ; the Home Office originally called for 14,000, who would be trained to qualify for first-aid certificates under the borough councils and their medical officers of health. A quota was given to each of the London boroughs, and it is understood that some of them have not yet secured a full enrolment.

On inquiry at the offices of the London County Council we were informed that those responsible for the ambulance service preferred to say nothing at the moment in view of the fact that a report on the subject is to be presented to the next meeting of the Council, fixed for November 14. Some of the criticisms are easily answered by the fact that the service is a new one and has to pass through the inevitable period of "growing pains." Its expansion has been very rapid, and it would be rather wonderful if the recruitment of personnel or material had been everything to be desired. Within the first three weeks of war 5,000 volunteers had been enlisted and over 100 stations opened, and within eight weeks the number of stations had been doubled and the number of volunteers increased by more than half. It is out of the question to suppose that 8,000 people joining an emergency service can immediately be disciplined in the same way as a regular ambulance service, each member of which has been carefully chosen and has undergone a long period of training. The people who have joined the service belong to all classes of the community, from titled ladies accustomed to driving their own cars to young men whose only experience has been on commercial lorries. The vehicles taken over for ambulance purposes are also of very diverse character; many of them are ordinary delivery vans fitted with racks to carry stretcher cases. A good deal of weeding out of both volunteers and vehicles has had to take place, and as time goes on there is every likelihood that the service will be as efficient as it is reasonable to expect, always bearing in mind that it is an auxiliary service, a temporary one, and to some extent voluntary. In any case criticism should be stayed until the London County Council has made its reply.

A WORLD ASSESSMENT OF BLINDNESS

The International Association for the Prevention of Blindness undertook in the past years an inquiry into the incidence of blindness throughout the many countries of the world, and of the regulations in force in those countries for the prevention of blindness. This report has now been published in French by the Egyptian "Concilium Ophthalmologicum."[1] It is an important piece of work of 310 pages, and full of information collected by the International Association. No fewer than thirty-seven countries responded to the inquiry. It is of much interest to compare the reports and to note the differences shown in them, not only in the variation in the main causes of blindness but also in the number of the blind in relation to the populations. In the East the figures are estimates, and they are high owing mostly to the widespread incidence of trachoma. In some of the Western countries the figures seem to be contradictory, for there is recorded a higher proportion of blindness in some of those countries where we know most is done, and done successfully, for the prevention of blindness. The reason for that apparent contradiction is that in these countries, like England, blindness is measured by its economic disability and not by a total absence of sight. The report is a valuable document and the Egyptian publication is well done.

CIRCULATION IN THE FOETUS

While continuing their radiological studies of the ductus arteriosus[1] with a greatly improved technical equipment, A. E. Barclay, Sir Joseph Barcroft, D. H. Barron, and K. J. Franklin were led to suspect their previous identification of this structure in the sheep foetus. They have now shown that this suspicion was justified, for in their latest paper[2] they present conclusive evidence from three distinct types of experiment. The most spectacular experiment was the retrograde injection of radio-opaque medium, via the femoral artery, in a newborn lamb with a very feeble heart-beat. The medium, faced by so low a resistance, passed up the aorta to the aortic valve and from the aorta, through the ductus arteriosus, into the pulmonary trunk and pulmonary arteries. Individual frames from the direct *x*-ray cinematographic record of the injection show quite clearly the anatomical relations of the ductus to the two great vessels that it unites. It is to be noted that the ductus joins the aorta distal to the point of origin of the brachio-cephalic artery, which corresponds to the innominate and the left subclavian arteries of the human subject. Having identified the ductus beyond dispute, the authors of the paper proceeded to investigate the courses taken by the blood flowing along the superior vena cava, and from the umbilical vein along the inferior vena cava. They found that all the superior caval blood goes into the right ventricle; thence it passes, on the one hand, into the pulmonary arterial system and, on the other, through the ductus arteriosus into the descending aorta. In contradistinction to the superior caval flow the oxygenated blood coming up the inferior vena cava from the placenta has two pathways. The bulk of it goes through the foramen ovale to the left side of the heart and passes via the aortic valve into the aorta, whence it supplies, through the coronary arteries, the heart, and through the brachiocephalic artery the brain. At the same time a small portion leaves the main stream in the right auricle and goes through the right ventricle to the pulmonary arterial system and, by way of the ductus arteriosus, to the descending aorta. The experiments described provide the first direct demonstration of the mammalian

foetal circulation, and it is of interest to see how closely previous observers have approached to the actual facts by various indirect methods. The times taken for functional closure of the ductus arteriosus and foramen ovale are not given in detail, but may be expected to appear in a later paper. It is not without interest that this description of the foetal circulation and identification of the ductus arteriosus has been published in the same year as the first successful ligation of a patent ductus in the human being.[3]

"FOREIGN PHARMACEUTICAL PRODUCTS: BRITISH EQUIVALENTS AND ALTERNATIVES"

In last week's *Journal* (pp. 868–75) we published under this heading a list of pharmaceutical preparations described as "foreign products," with an attempted correlation of British products. As indicated in the introductory paragraphs, the schedules were furnished to us by the Association of British Chemical Manufacturers, upon whom we relied for their accuracy. We have now received communications from a number of firms in this country informing us that certain of their pharmaceutical products are included in the list erroneously as "foreign products," whereas these products are manufactured in this country and in some instances have been so for a number of years. Sulfarsenol Laboratories, Ltd., for example, state that sulfarsenol is now manufactured in England at Alperton, Middlesex. The Denver Chemical Manufacturing Co. (London, N.W.9) state that for years past antiphlogistine has been made in England, and they do not anticipate any shortage. Warner and Co., Ltd., of Power Road, Chiswick, London, W.4, the proprietors of the trade marks "anusol" and "veganin," inform us that these products have been manufactured by them in England for a number of years. Gedeon Richter (Great Britain) Limited state that their products aurobin and kalmopyrin are manufactured by them in London. Ciba Limited state that dial tablets have been manufactured in this country for over twenty years, that they have ample stocks of coramine, and that the manufacture of this product will shortly begin in their new laboratories at Horsham. Laboratory Nativelle Ltd. (London, N.1) state that there is no shortage of stocks of Nativelle digitaline, and they have taken elaborate precautions both in France and in this country to ensure continuation of supplies. It should be pointed out that the introduction to the schedules published last week did not state that any or all of the products listed in columns 2 and 4 are necessarily equal in value to the products listed in column 1. The explanatory note reads as follows: "Column 2 gives the British product/s having the same essential composition as the item in column 1. Column 4 gives the British product/s having similar therapeutic properties and capable of replacing the product in column 1." No statement was made that any of the products in column 1 are unobtainable in this country. The mistake—in which we followed the Association of British Chemical Manufacturers—was in heading column 1 "Foreign Product," and including under that heading a number of proprietary preparations which, though understood to be of foreign origin, are manufactured in this country. In the list supplied to us the names of certain trade marks are set out as if they were the names of drugs. It has been pointed out to us that in doing so we may have infringed the rights of the owners of the trade marks under the Trade Marks Act of 1938. We can only express our regret for having inadvertently published material which may infringe a trade mark or which is incorrect or in any way misleading. Our purpose in printing the list supplied to us was to make information available to medical men concerning the British sources of supply in case they should experience difficulty in obtaining proprietaries of foreign origin which they had been accustomed to use.

CHRONIC ARTHRITIS AND GONORRHOEA

Acute gonorrhoeal arthritis is not uncommon and is recognized by its association with a recent acute infection, but gonorrhoea is easily overlooked as the possible cause of chronic progressive arthritis. Dr. R. J. Weissenbach and his colleagues[1] found that out of 1,485 cases of chronic rheumatic diseases 126 were gonorrhoeal in origin. In some of these cases the original infection had occurred many years earlier, and there had been acute or subacute attacks of arthritis or arthralgia before the chronic condition developed. One joint only was affected in thirty-three of these authors' cases, and more than three joints in seventy-one. The knees were most often attacked and then the feet, while in the upper limb the wrists were the most usual site of the disease. The old idea that the sterno-clavicular and temporo-maxillary articulations are especially liable to attack receives no support from these authors, who state that in no circumstances should symptoms in these joints be regarded as a guide in diagnosis. They attach importance, however, to the localization of the arthritis in the feet and ankles and especially to pain in the heel, and regard gonorrhoea as the principal cause of pain in this region and of the spurs or exostoses sometimes seen on the os calcis. A tendency to bony ankylosis, which they think especially liable to affect the knee and shoulder, is regarded by them as characteristic of gonorrhoeal infections, though others find bony ankylosis of the tarsus more common. Weissenbach and his colleagues emphasize the association of iritis with arthritis of the vertebral column, but it should be noted that irido-cyclitis has been reported in cases of ankylosing spondylitis without evidence of gonorrhoeal infection. Treatment with sulphonamide compounds was successful in five out of seven of the cases of acute gonorrhoeal arthritis. Out of thirty-seven subacute cases the disease was cured in nine and arrested in twenty-six, and out of three cases of the chronic form it was cured in two and arrested in one. These figures show that the treatment is worth trying in proved or suspected cases of gonorrhoeal arthritis.

SURGICAL PROCEDURES IN GENERAL PRACTICE

The series of articles under this heading, now resumed, was interrupted in April of this year to make room for a special series on War Wounds and Air Raid Casualties, concluded in our last issue.

FRACTURES OF THE NECK OF THE FEMUR

BY

PHILIP WILES, M.S., F.R.C.S.

Fractures of the neck of the femur are divided into two groups—intracapsular fractures of the neck proper and fractures involving the trochanters. Extracapsular fractures through the base of the neck belong, from a practical point of view, to the trochanteric group. The two groups are widely different as regards both prognosis and treatment.

Intracapsular Fractures

These fractures are seen principally in the elderly, although they may occur at any age. The blood supply of the neck of the femur is never very good, and with advancing years there are often porotic changes that seriously weaken the structure of the bone; it is then liable to fracture with minimum trauma. The fracture is usually close to the head, but it may be at an intermediate position in the neck. A common history is for the patient to trip and fall when walking about the house —there is no need for any more serious accident. The actual fracture may even occur before the patient falls, as from the jar of stubbing the toes; the fall is then the result of the fracture, not the cause of it.

Signs and Symptoms

The fractures are classified into two groups—adduction and abduction. The distinction is of importance, because the former are never impacted, whereas the latter usually are; the prognosis and treatment are therefore entirely different.

Adduction fractures (Fig. 1, left) comprise at least three-quarters of the total number. There is a great deal of pain, and the patient is often left lying where he has fallen until the doctor arrives. The typical position of the leg is one of adduction and external rotation; the latter may be so marked that the outer border of the foot is lying flat on the floor. There is shortening of the limb, which is partly apparent, due to the adduction, and partly real. Real shortening is caused by upward displacement of the main fragment and may amount to anything between one-half and three inches. There is tenderness on pressure over the great trochanter and in Scarpa's triangle, and pain on jarring the heel. Active movements are impossible and passive movements painful.

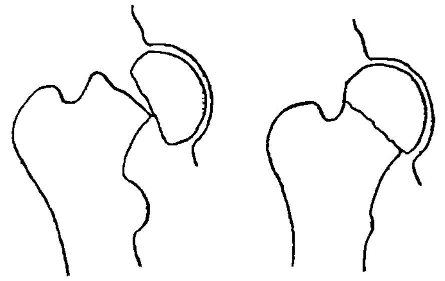

FIG. 1.—Intracapsular fractures. Left: Adduction fracture with upward displacement and internal rotation. Right: Abduction fracture with impaction.

Abduction fractures (Fig. 1, right) occur in about one-quarter of the cases. The pain is much less severe, and it is not at all uncommon for the patient to be able to get up, and even to bear weight, immediately after the fall. As there is almost always impaction of the fragments the limb does not assume the classical position described above. It usually lies with the foot straight or internally rotated, and the real shortening is not more than one inch. There is some pain and tenderness in the inguinal region. Active and passive movements may be possible over a limited range without causing very severe pain. Passive movements must, however, be examined with care for fear of disimpacting the fragments, and for the same reason no attempt must be made to elicit crepitus.

Diagnosis

The diagnosis in a classical case is immediately apparent from the history and the position of the limb. However, when there is not much displacement of the fragments, or when they are impacted, it may be difficult to be certain of the nature of the injury. It is unwise to move the patient too much for the purpose of making elaborate measurements of the bony landmarks because of the danger of causing further displacement. Nor should the patient be told to " try the leg out and see how you get on." Radiological examination must be made in every case in which there is the slightest element of doubt—that is, where an elderly person has had a fall causing pain in the hip. The interpretation of the radiographs may be difficult when the fracture is impacted; therefore films of good quality and in both antero-posterior and lateral planes are required. If first-class portable equipment is not available the patient should be sent to hospital by ambulance. To overlook the fracture may be a major tragedy for which the doctor might possibly be held responsible.

Prognosis

Impacted abduction fractures seldom give much trouble, but an adduction fracture is one of the most serious accidents that can befall an elderly person. In the past it was associated with a very high mortality, and even under modern conditions the death rate is higher than that in most other simple fractures. The patient is often already debilitated, there is some shock, the pain is severe and prevents the patient sitting up, and death ensues from pulmonary and cardiac complications. The risk is greatly diminished if the fracture is reduced at the earliest possible moment, so that he can sit up and move about a little without pain. If the patient survives—and at least 90 per cent. should do so —the prospect as regards the ultimate restoration of function is good. In the great majority of cases it is possible to obtain sound bony union by operative methods.

Treatment

Abduction Fractures.—The fragments are impacted and no attempt should ever be made to improve the position. The principal indication is to avoid disimpaction and ensure that no weight is carried on the leg until there is firm union. Many people have walked with these fractures from the start without coming to any harm, but they are taking a serious risk. The patient is put to bed without any retentive apparatus. Some movement is possible, and he can be propped up at once in the Fowler position to reduce the risk of pulmonary trouble. There is, however, no need to keep him in this position all the time; he can lie down at night, and it is an advantage for him to turn on to the sound side. Later he can be lifted into an arm-chair and taken out of doors in a wheel-chair. After ten to fourteen days the pain diminishes greatly and active movements are begun. Local massage assists in getting rid of any bruising, and general massage is helpful in maintaining the patient's condition. After six weeks a weight-bearing calliper is fitted; it is worn for about eight weeks, until the radiographs show good consolidation of the fracture. The earlier use of a calliper entails more risk because of the difficulty in ensuring that it carries the weight properly. The instrument is hard to fit, especially in fat people. The best type has a " bucket top " in place of the more usual ring; it is made of moulded leather, and laces in front to allow of easy adjustment. The bucket fits under the ischial tuberosity, from which the weight is transmitted down the side bars of the instrument in the shoe. The heel should not touch the shoe, and it carries no weight at all. It is advisable to check personally the fitting of a calliper. This can be done by slipping a finger into the patient's shoe under his heel; he should then be able to transfer his whole weight to the calliper without hurting the finger.

Adduction Fractures.—Treatment cannot be undertaken in a private house unless there is adequate provision of trained nurses and equipment. The great majority have to be transferred to hospital; the sooner this can be done the better the prognosis. Moving the patient on to a stretcher and carrying him downstairs may cause a great deal of pain. Attempts at splinting of any sort are nearly as painful, and are best omitted. The most satisfactory procedure is to give an intravenous anaesthetic, which should last long enough for the patient's transfer to the ambulance; it can, if necessary, be repeated during the journey.

SMITH-PETERSEN NAIL

Nearly every other form of treatment has been superseded by the use of the Smith-Petersen triradiate nail. The operation has a greater significance than setting a fracture usually implies; it is a life-saving measure. Once the fracture is fixed, the patient is free from pain, is able to move and to sit up, and the dangers of prolonged immobilization are removed. It is not a particularly dangerous procedure; there is little operative shock, and age alone is not a contraindication. The operative mortality is so low that it can safely be said that the chance of survival of any but a moribund case is greater with operation than without it.

The methods of introducing a Smith-Petersen nail and individual variations in technique are so numerous that description of detail is of little value. In general, the procedure can be divided into two stages: first, reducing the fracture; secondly, introducing the nail. Reduction at open operation is now almost universally abandoned in favoured of " closed " methods. Some surgeons perform the reduction by manipulation on the operating table immediately before inserting the nail. Others do it by traction while the patient is still in bed. The limb is placed in a Thomas splint suspended from a Balkan beam, and traction is applied by a weight (10 to 15 lb.) attached by adhesive strapping. The reduction is controlled by radiographs, and when the position is satisfactory the nail is inserted without removing the extension.

After-treatment also varies greatly with the surgeon. It is, however, becoming more widely appreciated that weight-bearing before consolidation of the fracture is unsafe—too many cases have occurred in which the pin has broken or become displaced. My own practice is to keep the patient in bed for six weeks. After two weeks, massage is begun and active movements of flexion and extension of the hip are encouraged, but rotation is avoided because the leverage may be great enough to dislodge the nail. It is advisable to wear in bed a shoe with a twelve-inch ruler fixed transversely to the heel to prevent external rotation by the weight of the limb. After six weeks the patient is allowed up in a weight-bearing calliper, which is worn until there is satisfactory radiographic evidence of consolidation. The pin may have to be removed at a later date, but it is not essential to do so unless it starts to extrude itself.

OTHER METHODS

Other methods of treatment may be required in the rare case in which the patient is unfit for operation or in which operation is refused. The choice then lies between fixing the limb in a long plaster-of-Paris spica extending from toes to nipple line (Whitman) and continuous weight traction as used for trochanteric fractures. In both cases radiographic control of reduction is essential. A successful result may be expected in 40 to 50 per cent. of cases.

Ununited Fractures

Non-union may be encountered when operative treatment has been impossible or has been neglected, or when displacement has recurred after operation. A satisfactory functional result is often obtained by osteotomy (McMurray). The femur is divided obliquely below the great trochanter and the distal fragment displaced inwards below the head. A plaster-of-Paris spica is applied and kept on for about three months, by which time union between all three fragments should have occurred. If operation is impossible there is no alternative to the permanent use of a weight-bearing calliper.

TROCHANTERIC FRACTURES

These fractures may occur at any age, but more usually in middle age or later, as the result of direct violence applied to the great trochanter or a rotation strain, or both together. There are two main types: (1) Fractures through the base of the neck or obliquely through the adjacent part of the great trochanter. The lesser trochanter may also be detached. The displacement is seldom pronounced, but there may be external rotation which opens up the gap between the fragments (Fig. 2, left and centre). (2) Comminuted fractures in which the neck seems to have been driven through the great trochanter. There is usually considerable displacement and marked coxa vara (Fig. 2, right).

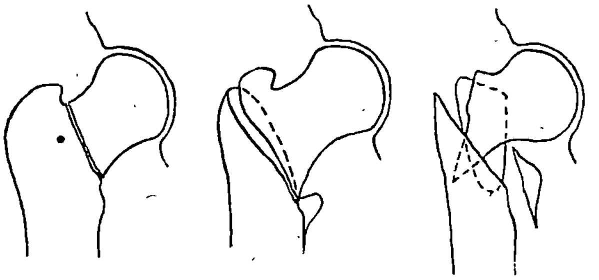

FIG. 2.—Trochanteric fractures. Left: Type 1, fracture through base of neck, without displacement. Centre: Type 1, fracture through great trochanter, with external rotation and detachment of lesser trochanter. Right: Type 2, comminuted fracture.

Diagnosis

On examination there is pain and tenderness over the great trochanter, but the pain tends to be less severe than with intracapsular fractures. There may be external rotation of the limb, and in the second type there is real shortening. The diagnosis is made on radiological examination. Either stereoscopic films or a lateral view is advisable, because in fat people the great trochanter may have fallen into a plane posterior to the neck and yet appear to be perfectly positioned in a flat antero-posterior film.

Treatment

TYPE 1

If there is excessive rotation the displacement is reduced under anaesthesia. Internal rotation is the only movement required; care must be taken not to exert too much traction or to abduct widely, or coxa valga may result. The reduction is controlled radiologically, and then a plaster-of-Paris spica is applied. For the application of the plaster the patient is placed on an orthopaedic table or, if that is not available, on a pelvic rest. In the latter case the shoulders are raised on a platform to the height of the pelvis in order to prevent lordosis. The feet are held by two assistants with the legs slightly abducted and flexed at the hips; about 10 degrees of flexion and eighteen inches separation of the feet are sufficient. The affected hip is kept in internal rotation and the knee of that side flexed 45 degrees. The line joining the antero-superior spines must be perpendicular to the median plane of the body. The bony points are well padded with felt, or the whole area to be included in the plaster may be covered with a layer of wool secured by a cotton bandage. A well-fitting plaster is then applied, extending from the costal margin to the tips of the toes. The sound leg is not included. The plaster must be worn for at least twelve weeks. If weight-bearing is started too soon the neck of the femur may bend at the site of fracture, causing coxa vara. An active patient may be able to get about on crutches after the first week or two.

An alternative method of treatment is the insertion of a short (2½ to 3 inch) Smith-Petersen nail. The operation is easy in experienced hands and does not require any elaborate control of direction. The hip is then protected by a short plaster spica stopping above the knee, and weight-bearing may be begun after a few days. The plaster should not be discarded for about eight weeks.

TYPE 2

The fracture requires reduction because of the varus deformity. The most satisfactory method is by continuous skeletal traction. A Smith-Petersen nail cannot be used because of the comminution. Traction is conveniently applied by means of a Kirschner's wire through the femur; the leg rests in a counterbalanced Thomas splint in a position of full abduction and internal rotation.

The leg is first placed on a Thomas splint of a suitable size; the ring should be large enough not to cause pressure and yet not so large as to get in the way. Strips of flannel bandage four inches wide are folded round the bars and beneath the leg and secured by large safety-pins or paper clips to the outer bar. The splint is then suspended from a Balkan beam, preferably by four cords, one from each corner of the splint. The cords are passed round pulleys and carried to the head of the bed, and weights are attached to counterbalance the weight of the limb. Loose shot in canisters provide a convenient method of varying the weight, which is so adjusted that when the patient moves—for example, to sit up or to use the bed-pan—the splint and limb move with him without effort. The foot is supported at right angles by a foot-piece attached to the splint or by a strip of adhesive plaster on the sole leading to another cord ending in a 1-lb. weight. The foot of the bed is placed on nine-inch blocks so that the patient's weight will provide countertraction.

When the splint is in position a Kirschner's wire is inserted. This can be done under local anaesthesia: an area about one inch in diameter on each side of the leg is freely infiltrated with novocain down to and including the periosteum. The wire is inserted well clear of the knee-joint and its suprapatellar pouch—that is, about two inches above the adductor tubercle. The stirrup is applied and the wire strained as tightly as possible to prevent bending; it should give a very high-pitched note when struck. The cord for traction is attached to the stirrup and passed over a pulley on the lower upright of the Balkan beam.

It is advisable to start traction with a considerable weight, say 25 to 30 lb., so that reduction is effected rapidly. Radiographs are taken after twenty-four hours, and if the position is satisfactory the weight is reduced to 10 lb. A heavy weight must not be used for long without *x*-ray control or it will produce coxa valga. The fragment consisting of the lesser trochanter does not return to its proper position; it joins by fibrous union and does not cause any subsequent trouble. After a week a knee-flexion iron is attached to the Thomas splint in such a position that the hinges are in the plane of the knee-joint. The flannel strips are transferred to this iron and another cord and weight are provided to counterbalance it. Movements of the knee are made at least once daily under supervision; it is possible to obtain, with assistance, at least 90 degrees of flexion. Traction is maintained for twelve weeks or until firm consolidation is shown radiologically—if the weight is removed too soon the varus deformity is liable to recur. With a heavy patient it is advisable to use a weight-bearing calliper for another six to eight weeks.

TUBERCULOSIS IN WAR TIME

DEPUTATION TO MINISTER OF HEALTH

The Minister of Health, Dr. Walter Elliot, on October 27 outlined to a deputation representing the National Association for the Prevention of Tuberculosis, the Joint Tuberculosis Council, and the Tuberculosis Association, at which representatives of the Society of Medical Officers of Health and the London County Council were also present, the steps which had been taken to ensure that tuberculous persons continue to receive treatment while keeping an adequate reserve of beds for air raid casualties.

War-time Accommodation

Dr. Elliot said he was having the greatest difficulty in persuading people that hospital services were available now just as before the outbreak of war. In particular it had always been intended that the anti-tuberculosis services should be maintained in war time. Although some patients had been discharged from sanatoria and other institutions to allow of accommodation for casualties, about two-thirds of the 28,000 beds provided for the treatment of tuberculosis in England and Wales remained available throughout the early weeks of the war for their peace-time purpose, though naturally this proportion varied in different parts of the country. If through some misunderstanding actively infectious cases had been discharged they should be sought out and brought back for treatment.

An instruction issued on October 4 had specially emphasized the importance of the tuberculosis services. A long-term policy was particularly desirable in this field. Steps had been taken to remove any misunderstanding which might have led to the refusal of residential treatment to tuberculous patients in need of it, and also to enable a substantial number of smaller tuberculosis institutions originally included in the casualty scheme to return wholly to their normal functions. This had made available some 5,000 more beds. In addition, as more and more of the hutted annexes to hospitals were completed, so more and more beds at present allotted to casualties would be released.

Other services were also returning to normal. In London, for example, the dispensary services, after an initial lull and difficulties owing to the temporary transfer of personnel, were resuming almost pre-war activity. In some reception areas these services had, indeed, been expanded. He would welcome arrangements between local authorities in any region whereby the accommodation in their various districts might be pooled to enable hospitals to be assigned wholly to casualty or tuberculosis work, and thus avoid, where possible, the mixing of tuberculous and non-tuberculous patients. One such arrangement is already in force in the West Riding of Yorkshire.

The Minister welcomed the efforts of the organizations represented to promote action along these lines. He assured them that the importance of maintaining facilities for the surgical treatment of both pulmonary and non-pulmonary tuberculosis was fully recognized. He was also fully alive to the need for making satisfactory arrangements for the treatment of tuberculous patients in the Army, Navy, and Air Force. This question was at the moment under consideration with the Services.

The Minister welcomed particularly this opportunity of discussing the problem frankly with the representatives of all the different sides of the tuberculosis services. He suggested that they should appoint a small liaison committee which could report to him how the instructions so far given were being carried out and how the steps taken were working in practice. He promised also to consider carefully the other representations of the organizations.

Those who attended the meeting with the Minister were:

Representing the National Association for the Prevention of Tuberculosis, the Joint Tuberculosis Council, and the Tuberculosis Association.—Sir Percival H.-S. Hartley, Sir Henry Gauvain, Dr. R. A. Young, Professor Lyle Cummins, Dr. G. Lissant Cox, Dr. G. B. Dixon, Mr. H. Arthur Baker, Councillor R. W. Brosch, Dr. S. Vere Pearson, Dr. J. B. McDougall, Dr. G. T. Hebert, Dr. Lloyd Rusby, Mr. J. E. H. Roberts, and Dr. J. H. Harley Williams.

Representing the Society of Medical Officers of Health.—Dr. P. L. T. Bennett and Dr. James Ferguson.

Representing the London County Council.—Dr. W. Allen Daley and Dr. A. M. Hewat.

WAR-TIME RADIOLOGY

The British Institute of Radiology, although it has abandoned for the time being its monthly sessional meetings, is continuing its principal functions; its office door is still open in Welbeck Street, the regular issue of its journal is being maintained, and instruction is given under its auspices for the D.M.R.E. Major D. B. McGrigor, the new president of the Institute, on being inducted into the chair at a meeting on October 19, said that it was hoped during the winter, if circumstances permitted, to have a one- or two-day meeting at which the two annual memorial lectures—the Mackenzie Davidson and the Silvanus Thompson—together with the Skinner Lecture of the Faculty of Radiology, might be delivered, but the usual conference held in December, with its attendant exhibition, has had to be abandoned. Many of the members of the Institute are on service at home or overseas, and Major McGrigor gave a word of advice to young radiologists going or expecting to go abroad. He said it appeared necessary to remind young radiologists not to expect in their new environment the ready-to-hand conditions of work to which they were accustomed in the civil hospitals and laboratories at home, where the turn of a tap or the press of a switch instantly brought whatever was required. They must cultivate, he said, a rather different outlook. Their apparatus was, indeed, provided for them, but the convenience of their *x*-ray rooms and dark rooms would largely depend upon their own initiative. In other words, it was left for them to fashion their departments, taking advantage of such conditions or amenities as offered themselves, and relying upon their own resourcefulness and adaptability. They might not know what electrical supply was available, and in all sorts of matters which were taken for granted at home they would come up against primitive conditions, and must be prepared to be handymen, at least during the first month or two.

Reports of Societies

IMMUNOLOGICAL PROBLEMS OF DIPHTHERIA

At a meeting of the Section of Pathology of the Royal Academy of Medicine in Ireland on October 13 the president, Dr. R. A. Q. O'Meara, delivered from the chair his presidential address, "A Critical Consideration of Some Immunological Problems, with Special Reference to Diphtheria."

Dr. O'Meara first considered the two principal experiments supporting the therapeutic value of diphtheria antitoxin—that of Fibiger in Copenhagen in 1898, and that of Roux, Martin, and Chaillon in Paris in 1894. Although Fibiger obtained good results with diphtheria antitoxin he was dealing with such a mild disease that its fatality rate of 12.2 per cent. in untreated cases was no greater than in areas where severe cases were actively treated with antitoxin to-day. There was evidence that the gravis type of diphtheria bacillus was associated with diphtheria in Paris about the time of the experiment in 1894. The French workers gave their results in two groups of cases—"angines" and "croups"—which for comparison with modern figures might be referred to as "non-laryngeal diphtheria with faucial involvement" and "laryngeal diphtheria." In the first group the fatality rate without serum treatment was over 30 per cent. for the period of the experiment. Serum treatment brought the fatality rate down to 12.4 per cent. Figures from the annual reports of Cork Street Fever Hospital showed that in a comparable group of actively treated cases the fatality rates for 1936, 1937, and 1938 were 17.4 per cent., 10.5 per cent., and 11.6 per cent. The dosage in any case in the original experiment did not exceed 8,500 units and was probably not more than 5,000. Against this, doses of 120,000 units or more were given to-day in severe cases. The conclusion would appear to be that there had been no improvement in the treatment of the toxaemia of diphtheria since antitoxin had been introduced, and that modern antitoxin, unit for unit, was less potent than that originally employed. The principles guiding the development of antitoxin in the interval had been mainly directed towards purification so as to ensure the maximum number of units in the minimum volume. The study of clinical efficacy of antitoxin had been relegated to a minor position. The development of diphtheria prophylaxis and other methods of immunization was suffering also by the fact that avoidance of reaction was being made the first criterion for an immunizing agent. The immunologist had become dazzled by the achievements of the chemist in isolating fractions of the organism which had antigenic properties and which could be injected without causing reaction. On the other hand, the work of Pasteur and the pioneers appeared to show that in order to get solid immunity against the causal organism it was necessary to use something very close to the whole organism and not a fraction of it. If the modern tendency continued it might eventually lead to the abandonment of immunizing methods as of no practical worth.

Professor J. W. Bigger said that serologists and immunologists had shown in recent years a tendency to become too academical. The president had pointed out that the results obtained in laboratories must be judged by the results of their application to the human body. It was of value to be reminded that the scientific evidence on which the use of antitoxin was based was slight. There were various reasons for this, but the chief was that from the beginning the treatment had been so obviously successful that few if any physicians had felt justified in continuing to treat control cases of diphtheria without antitoxic serum. There were three distinct types of diphtheria bacillus, which gave rise to differing clinical forms of the disease. The president had made a good case for believing that the diphtheria prevalent in Paris in 1894 was in the main due to the gravis type of bacillus. Diphtheria in Dublin to-day was due to the same type. It would not be true to say that antitoxin was useless in the treatment of diphtheria; it had definitely reduced the fatality rate of both gravis and mitis infections. But the treatment of diphtheria by antitoxin had not improved to the extent which one would have expected.

Professor **Hans Sachs** said that it was impossible to doubt that serum therapy was of value. Antitoxin not only neutralized the toxin but made it disappear altogether from the blood. It was possible to distinguish an antitoxic action and a non-specific action of the serum. The specific and the non-specific actions on the organism were quite different.

Dr. C. J. **McSweeney** said that the president's paper pointed out the limitations of serum therapy in the management of gravis diphtheria. There was no doubt that in Dublin during the last five years the variety of diphtheria had been quite different from that which had prevailed in the British Isles and in Ulster. He showed a chart of the mortality rate which proved that the rate in Dublin was higher than in Cardiff, although the treatment of the disease was exactly the same in the two places. The hallmark of toxic diphtheria was the amount of faucial oedema; other factors were the extent of "bull neck" and the occurrence of haemorrhages into the skin and from the mucous membranes. These constituted the clinical signs of gravis diphtheria. The commercial antitoxin available at present seemed to check the spread of the membrane, but it had little if any effect on the undefined toxic factor. In his opinion 90 per cent. of the deaths happened within ten days of the development of the disease. With a very virulent organism something more potent than the existing antitoxin was required in order to ensure a minimum mortality rate.

Dr. G. C. **Dockeray** said that in 1931 he had tried typing diphtheria bacilli in Dublin and had found that they were predominantly of the gravis type. It was strange that the mitis type, which was haemolytic on culture, should not cause haemorrhagic lesions as a rule, whereas the gravis type, which was not haemolytic, should. Dr. A. R. **Parsons** thought it difficult to know how much antitoxin to give. Some years ago good results had been achieved by the administration of 4,000 or 8,000 units; to-day it was said by some workers that the dosage should not go beyond 100,000 units, but that it was quite safe to give that amount. Was the present antitoxin not so good as formerly? Dr. B. **Moran** referred to the diversity of factors which had to be considered when dealing with the problem of diphtheria. Dr. R. W. **Shaw** said that if a prophylactic known to produce a reaction in children were used it would be difficult to get permission from the children's parents to employ it. Dr. W. **Hayes** remarked that the concentration of antibodies had been a purely technical achievement and little real progress in treatment had been made since the 1890's. In small-pox an attenuated small-pox virus, in which all the elements of the real disease were present, was used as a prophylactic. In measles, immunity was procured by modifying the whole disease. Both methods gave an immunity comparable to the natural one. In diphtheria and in scarlet fever the degree of immunity produced artificially was not comparable with that following the disease itself. Dr. J. **McCann** observed that in the early days serum had been given subcutaneously with very good results; now it was given intramuscularly or intravenously. If the serum was administered in this way a large number of units might be excreted from the blood and lost almost as soon as they had been given; he suggested that serum might be injected subcutaneously as well. Dr. W. P. **O'Callaghan** asked if there was any reason why infants in the maternity hospitals should not be treated with diphtheria prophylactic from birth. Dr. W. G. **Elliott** asked if children inoculated with diphtheria prophylactic were in danger of becoming carriers; if they were they would be a source of danger to other school children. Dr. **Alan Thompson** wanted to know if there was any hope of getting a better serum against gravis, and if gravis yielded a toxin in sufficient amount for the immunization of horses.

The **President**, in reply, said that his object had been merely to show that a problem existed, and not to say that diphtheria antitoxin should not be used in the treatment of diphtheria, or that diphtheria prophylactics should not be employed. Certain cases of severe diphtheria were not amenable to antitoxic therapy in spite of the fact that many alleged improvements had been made since the introduction of diphtheria antitoxin. The existing prophylactics were capable of yielding a high degree of immunity against diphtheria. It was well worth while using T.A.F., but parents should not be told that the child would certainly be protected against the disease. The fatality rate would soar in the absence of treatment with antitoxin. In immunology there had been too great a gap between laboratory and clinical work. There need be no relation between the haemolysis produced by the mitis type on culture and clinical haemorrhagic lesions. The latter would be due to capillary damage and not to haemolysis. In immunization it was important to use the whole organism and not isolated parts or products of it. It was said that infants in maternity hospitals were immune to diphtheria, and if this was so it would hinder the development of immunity from a diphtheria prophylactic. The immunity-forming mechanism of the infant might not be developed at so young an age. Children who received prophylactic inoculations did not necessarily have their tendency to become carriers increased thereby.

Correspondence

War Wounds of the Limbs

Sir,—The publication of Dr. Trueta's inspiring little book on the treatment of war wounds and fractures and the opinions expressed by Mr. R. Watson-Jones in his admirable letter in your issue of October 21 (p. 826) all point to a firm belief in plaster-of-Paris as opposed to other methods of fixation. Böhler's technique and his convincing contributions to the surgery of fractures are responsible largely for the revival and improvement of ancient practice.

It may be useful at the present time to remind students and the younger generation of surgeons that their forefathers had similar beliefs. In my student days Erichsen's *Surgery* was the favourite textbook for those beginning the study of surgery. In vol. i of the tenth edition, 1895 (forty-four years ago), it is stated that the unpadded plaster cast was employed at University College Hospital. Some modification of this was introduced, but there is a condemnation of the padded cast which is written in words almost identical with those of Böhler.

Thirty years ago I practised and published an account of the ambulatory treatment of fractures in plaster-of-Paris, a lesson learned from a visit to St. Thomas's Hospital and to the clinic of Kocher of Berne. Splints such as Carr's splint for Colles's fracture, Liston's long splint for fractures of the thigh, and Cline's splint were never used by my colleagues or myself. They were obviously ineffectual. It was the influence of Sir Robert Jones, and the knowledge of the unrivalled results his followers obtained in the last war, which induced many of us to abandon plaster-of-Paris as a routine in favour of his simple fixation splints. This change-over from plaster to splints was confined largely to war wounds. It is surprising to find how few modern writers understand the admirable extension and fixation which can be obtained when these frames and splints are properly applied. Jones was modest about his own methods; he was thoroughly familiar with those of Böhler and interested in their development and use, but he appeared to avoid plaster when he could.

The late Lord Moynihan used to speak cryptically of "the hypnotic tube" which he inserted after gall-bladder operations. He subsequently explained that he used this term because he slept better when the tube was *in situ*. So it is with Jones's splints. By their use we are relieved of misgivings when we are not quite certain if the application of plaster is free from risk or, if applied, might require quick removal to obtain more accurate position.

I have beside me not only Böhler's and Trueta's books, but also, among others, *The Orthopaedic Surgery of Injuries*, *Injuries to Bones and Joints*, and *Notes on Military Orthopaedics*. These last three volumes are by Robert Jones. May I venture to advise others who are only familiar with plaster technique to include them in their library if engaged in war work.

One important point is mentioned by recent writers but has not been sufficiently emphasized. Wounded soft parts, especially when infected, require the same amount of fixation as broken bones. I drew attention to this in the *Lancet* (1936, 2, 1010) when dealing with the question of infected fingers and hand. In cases of streptococcal lymphangitis I found splinting the arm was essential. Bier's bandage was a help, but stupes, arm baths, etc., were forbidden. We now have the sulphonamide group of drugs as a powerful ally. Conservative treatment with rigid fixation was successful. Mortality too often was the result of too active surgical intervention. War wounds of the limbs are being considered along similar lines. Mr. Watson-Jones mentions that amputation has almost disappeared "from the repertoire of the traumatic surgeon." I do not like the words "traumatic surgeon," but he says very truly, at the end of a most helpful letter: "Amputation—to be performed only when the main artery is destroyed, so that gangrene is inevitable." The possibility of the reconstruction of a shattered limb, by methods which were well tried during and after the last war, must always be remembered by the surgeons working near the front line.—I am, etc.,

Aberdeen, Oct. 24. W. I. de C. Wheeler.

Treatment of Infected Fractures

Sir,—Although a physician and general practitioner, I have just read with the greatest interest and admiration Professor Trueta's description of his treatment of air raid casualties. The technique of such a master of his art, by means of which a mortality of 0.6 per cent. resulted in a series of 1,073 cases, fully justifies your laudatory comments, and if Professor Trueta's method is applied as described by him it does seem as if "the whole treatment of war injuries will have been revolutionized."

At the present time the criticism of the value of Professor Trueta's contribution to war surgery in the letter by Mr. R. Watson-Jones (*Journal*, October 21, p. 826) is singularly unfortunate. The effect of this letter may be to deprive a number of younger surgeons (who have not had any experience of war surgery) of the pleasure and educational advantages of reading the book. Mr. Watson-Jones should remember that the only fair way in which destructive criticism can be effectively employed is when it is supported by rebutting statistics instead of vague generalities. What statistics can Mr. Watson-Jones supply in regard to modern war casualties which can compare with those of Professor Trueta's six deaths in a series of 1,073 cases?

One astounding assertion appears in Mr. Watson-Jones's letter. He states towards the end of his third paragraph that "the crushed and mangled limbs of severe motor crashes, *which differ in no respect from the injuries of modern warfare*, are restored to normal in a very large proportion of cases." No surgeon with any experience of either modern war injuries or those of the 1914–18 war would agree with the assertion which I have italicized. The remainder of this letter is a re-hash of hitherto employed orthopaedic methods, and gives me the impression that Mr. Watson-Jones has not read Professor Trueta's book carefully, and that possibly a further perusal of it may cause him to revise his views.—I am, etc.,

Manningham, Bradford, Oct. 23. A. Hayes Smith.

Psychological Casualties in War

Sir,—Those of us who had to deal with the so-called shell-shock patients in the last war had hoped that something would be done next time to prevent a repetition of the psychiatric illnesses which were lumped together under that unfortunate name. The need for prevention does not require to be stressed. The intense misery of the patients, the infectious nature of the disease, so that it became a serious problem for those responsible for the prosecution of the war, and the unending burden to the community should be sufficient reasons for inquiring if there are any means of prevention available.

From many quarters conclusive evidence has been obtained that in a large number of instances a history of psychiatric illness was forthcoming before enlistment. It is reasonable to suppose that if these patients had been excluded from the Army there would have been fewer psychiatric casualties. It is generally believed that the bodies responsible for the examination of recruits are instructed to inquire into the mental history of the patient, but some of us who are interested in this aspect of illness are beginning to feel that the meshes of the net are too wide.

I have seen recently two persons who would not have been enlisted if attention had been paid to their histories. In one of these there was a prolonged history of repeated failure. He had to be taken from one school to another until when he was 15 his doctor, who had had him under observation for many years, wrote to his father that after due trial he had come to the conclusion that the boy could not stand the strain of public school life, and that all attempts to make him do so should be given up. Thereafter his education was conducted by tutors, and an attempt was made to study for a professional career. After he had passed some examinations his health again broke down, and for about a year before being called up for the militia he was occupied in trying to get it restored. The chief symptoms in each illness have been insomnia, attacks of terror—always worse away from home—severe indigestion, failure of concentration. Though this history and a certificate from a leading physician that the lad was totally unsuited for military service were communicated to the board, nevertheless the boy was passed fit for military service. The other patient joined the Territorials a year ago, and broke down with acute nervous symptoms about ten days after the outbreak of war. His history, though not so marked, has many incidents in it of minor nervous illnesses throughout his life. One accustomed to the study of psychiatric histories would certainly have suggested further investigation before he was accepted.

Even two swallows do not make a summer, and I have to admit that these are my only two specimens of the bird. But in conversation with my colleagues I have found that they also have been finding other examples. There must be many others.

It would be a great kindness if you, Sir, would afford me the hospitality of your columns to get this question investigated. If those of your readers who have knowledge of similar cases could send details to me at St. John's House, Smith Square, S.W.1, it might be possible to find out whether this is a serious problem or not. If these psychopaths are being generally enlisted, then we are doing our best to provide many occupants for psychiatric beds, not only because of the numbers actually enlisted but also because of the highly infectious nature of hysteria.

I am not suggesting a remedy for this state of affairs until I know something of the magnitude of the problem, but publicity may induce those responsible to realize that it is not unimportant.—I am, etc.,

London, S.W.1, Oct. 30. T. A. Ross.

Psychological Treatment Centres

SIR,—A perusal of your correspondence columns recently, as well as those of a great diurnal contemporary, suggests that the zeal of some of our colleagues with a passion for psychotherapy may be undermining their judgment. It is natural that in their desire to be useful in this war, being baulked in their aspiration to treat the arch-dictator himself, they tend to exaggerate the importance of their possible part in the national effort. I am not sure that it is a good thing to advocate the setting up of "psychotherapeutic centres" throughout the land, unless these are to function as components of general hospitals; partly because the divorce of psychotherapy from general medicine is apt to have as its consequence a divorce from sanity, and partly for reasons connected with the following considerations.

A battle-cry for the rallying of psychotherapeutic centres may not have the reassuring effect on the public mind that is intended. It is reminiscent of a memorable saying of Dr. Edward Glover's, whose vision some years ago of a "solid phalanx of child analysts" aroused emotions in our hearts closer to the Roman associations stirred by the metaphor than its author could have desired. There is a risk at the present time of creating a national hypochondriasis by too wide advertisement of emergency psychotherapy, with its implications that many people are in special danger of breaking down under war conditions. The article by Dr. S. Barton Hall in your issue of October 21 (p. 801) shows the same general tendency. The cases he records and attributes to the pressure of war industry are not different from many that we have all encountered in times of peace. It would be a pity to encourage the belief that such cases are likely to be specially frequent now. The fact that these particular patients broke down so soon after engaging in war work points to their being special cases, ripe for a breakdown in any event. I have rarely seen a patient in whom overwork alone or principally was the cause of an illness of this type.

There are arguments even for thinking that mental breakdowns of any sort may be fewer in the civil population than during peace. Thus in the last war admissions to mental hospitals of females as well as males showed no increase, but rather the reverse. I have never heard of any data which purported to show a rise in psychoneurotic and minor psychotic illness, not admitted to mental hospitals, during the years 1914–18. On the other hand, I have met a number of "neurotic" people who were better during these years than before or since.

Moreover, on general grounds, which it would be tedious to detail here, there are reasons for expecting an improvement in the mental morbidity rate of the nation during a war. The only potential cause of a notable increase in the incidence of psychoneuroses among the civilian population is that from air raids; and even this, on the evidence of the only Spanish psychiatrist whose experience has been recorded in your columns, Dr. Mira, is possibly a mirage.

Dr. Geoffrey Evans (October 7, p. 742) has advocated that doctors in general should examine themselves and their own mental attitude at the present time. Psychotherapists of all sorts might take more comprehensive stock of the problems from a psychiatric angle if in addition they were to read Sir Robert Hutchison's address at the Canadian Meeting of the British Medical Association on "Hypochondriasis, Individual and National."—I am, etc.,

Matlock, Oct. 21. R. D. GILLESPIE.

SIR,—The essence of psychological treatment centres as suggested by me (*Journal*, October 7, p. 743) was that they provided immediately all the necessary arrangements for ensuring early contact between therapist and civil casualty—will Dr. W. Mayer-Gross (September 30, p. 701) and Dr. R. Louis Rose (October 21, p. 829) kindly note?—and this in a way which no existing national organization could.

I am grateful to Dr. R. F. Fidler (October 14, p. 783) for so helpfully calling my attention to the opening of psychiatric clinics in out-patient departments of general hospitals, but the phobic need of potential psychotics, who in point of fact avoid such clinics, calls for centres with a more euphemistic title and more accessible venue. If after six weeks the profession as a whole is unaware of this Ministry of Health scheme, is it likely that the lay public will know? And when they know, will they not get the grim impression that secret arrangements were being made for ensuring their mental detention rather than their psychological freedom? The Barcelona experiences indeed point to the coming urgency for psychotic psychiatry, but also for the early establishment of preventive centres. Why wait till the chain breaks here too? Would it not be wiser to strengthen the weak links at once to preserve the chain's integrity?

The kindly notice of my plea by Sir Walter Langdon-Brown (October 14, p. 783) warned the profession that if it did not organize for psychotherapy now the authorities might disastrously let pass this valuable opportunity for launching a long-needed National Service. We can only have such organization either (A) from without or (B) from within. Scheme A at the dictation of an authoritarian political Ministry would be foisted forcibly on an unready profession when emergency acutely demanded that something be done quickly and in wholesale manner. Such a scheme would grow on us by accretion absorbing us along beautiful bureaucratic lines, uniform but unalterable, growing—but only as crystals and dead minerals grow—to embalm fossil Medes and Persians. Scheme B must be the outcome of voluntary co-operation in a comprehensive plan evolved among ourselves by co-ordination of living nuclei into related groups within the profession, a scheme growing by intercalation of outside material, growing not perhaps in such straight lines but growing as living organisms grow by preserving both integrity of life and inherency of adaptation. The "enlistment" suggested by me is a voluntary process under Scheme B, but until the Central Emergency Committee of the B.M.A. or some correlative body sees fit to ask all active psychotherapists to enlist *as such*, Scheme B cannot begin to function, as Dr. R. Louis Rose aptly (October 21, p. 829) pointed out.

It is asking too much of authoritative psychiatry to supply all the requirements of this new and gigantic psychological situation. The "no man's land" in psychopathology is as yet unexplored by official guides and unmarked on official maps. Scheme A at this juncture would have too many scotomata. After this war there will have to be a specific diploma in mental analysis, but meanwhile in the preparation of an itinerary every pioneer must be called in, every discovered tract must be marked in, and all this must be done now.

There is one notable precedent in medical history for the formation of local treatment centres as under voluntary Scheme B. During the distracted period of the Great Plague in the autumn of 1665, when all measures of official appeasement had failed to stop the spread of the epidemic, the poor apothecaries of London, the first "general practitioners," courageously remained in the "danger zones" when the theorist physicians and barber-surgeons had removed to safer areas. National acknowledgment came later when a Royal Charter of Incorporation of the Society of Apothecaries set the seal of public approval on their practical and humanistic efforts. Perhaps—who knows?—the Society of Apothecaries itself will come forward and offer to regulate and co-ordinate "Psychological Treatment Centres" in this grave hour of the nation's newer and stranger peril.

While early Rome slept, lulled into security by the comparative absence of frontal attacks and the safe silence of its black-out night precautions, barbaric Germanic invaders were secretly scaling into its strongest fortress because the cocksure sentries on that hill were fast asleep. It was a "mere goose" who saw the danger and issued the call. Civilization was saved—that time. Our "citadel" is being insidiously invaded on one of its strongest hills, and if a mere goose can but arouse all the psychological sentinels to man the mental walls at once that goose would willingly make way for more proper gander!—I am, etc.,

Treatment of Pulmonary Oedema from Gas

SIR,—I have read with interest Dr. H. L. Winter's suggestion as to the possible value of calcium salts in the prevention of pulmonary oedema in gas casualties (*Journal*, October 21, p. 828). I had previously considered the possibilities of these salts in this connexión, and had formed the opinion that their value was problematical.

The observations of Gold (*J. Pharmacol. exp. Therap.*, 1938, **34**, 169; and *Arch. int. Med.*, 1928, **42**, 576) that in the control of experimental pleural exudates large doses of calcium were required to inhibit the effects of moderate irritation, while intense irritation was not appreciably influenced by even large doses of calcium, indicate that calcium salts would in all probability be valueless in the severe cases in which theoretically they were most indicated—a probability in accord with my experience in other acute inflammatory manifestations. Transience of action would render calcium salts valueless in the prophylaxis of pulmonary oedema, as in the prophylaxis of other inflammatory lesions, while in their therapeutic application in the less severe cases early, adequate, and continued dosage is essential if any benefit is to follow. In the absence of experimental evidence confirming the value of calcium salts in severe pulmonary oedema in gas cases, the possible limitation of this therapy must be realized.—I am, etc.,

Newcastle-upon-Tyne, Oct. 24. A. E. W. MCLACHLAN.

Treatment of Eye Injuries from Gas

SIR,—In a recent paper in the *Journal* by Mr. Arnold Sorsby (September 23, p. 641) and a still later one by Colonel E. M. Cowell (October 14, p. 778) the use of a 2 per cent. solution of bicarbonate of soda as an eyewash is recommended against mustard-gas irritation, and this appears to be generally accepted as the standard treatment in this country.

From lack of opportunity to make any comparative tests I cannot give a personal opinion on the relative value of any substitute or alternative remedy, but I venture to draw attention to a paper by Dr. Georges Bonnefon, an ophthalmic surgeon of Bordeaux, in which from a large experience gained in the great war (1914–18) he advocates the use of a saturated solution of sodium sulphate (800 parts) mixed with 200 parts of syrup of sugar. He claims that any sufferer, if provided with this in a pannikin and a pad of non-medicated absorbent cotton-wool, can lave his eyelids or even douche the eyes himself (unless too tightly closed by swelling) with less need for assistance in bathing by orderlies or other overwrought attendants. The lotion should be renewed every few hours, since it becomes soiled, and, indeed, when loaded with secretion becomes an irritant itself after repeated use. If the sufferer has reached a hospital where an eye-bath can be provided the treatment can be made more efficacious and penetrating with the lotion lukewarm. But the principle to be aimed at is to encourage the escape of the tears and on no account to bottle up them or the pores of lid glands by the use of ointments to the lid edges.

Whether the syrup has any chemical advantage against "l'ypérite, ou sulfure d'éthyl-dichloré," as the French call it, is not stated. It may possibly make the solution more tenacious, but it would be interesting to know whether it is essential, since sugar might be rationed if in greater demand than Glauber's salt. Moreover, one ingredient instead of two makes for simplicity in preparation. The value of the local application of a strong solution of sulphate of magnesia in reducing inflammatory swelling is well known, and I suggest that it might be worthy of trial in mustard-gas irritation. Like Sorsby and Cowell and others, Dr. Bonnefon condemns the use of cocaine as a local anaesthetic in the above cases on account of its tendency to cause desquamation of the corneal epithelium. In its place he advises butelline. But as a less transitory and more efficacious analgesic he prefers a 2 per cent. solution of dionine. His original paper appeared in the *Gazette hebdomadaire des Sciences médicales de Bordeaux*, No. 11, March, 1939, entitled "L'Œil Ypérité: son Traitement."—I am, etc.,

Edinburgh, Oct. 16. GEORGE MACKAY, M.D., F.R.C.S.ED.

SIR,—In his interesting paper on ophthalmic services to the civil population in national emergency Mr. Arnold Sorsby states (*Journal*, September 23, p. 641) that experimentally immediate irrigation after the application of liquid mustard gas to the cornea is of no value. Would Mr. Sorsby very kindly say if liquid mustard gas is soluble in any vegetable fat such as olive oil or castor oil, and if any experimental work has been done on the value of immediate use of any such solvent which is harmless to the eye?—I am, etc.,

Oct. 10. AN OCULIST SOMEWHERE IN FRANCE.

⁂ We print below Mr. Sorsby's reply. The subject is also dealt with in a leading article at page 915.—ED., *B.M.J.*

Liquid mustard gas is fat-soluble. I do not know of any experimental work to test whether irrigation with oil is more effective than irrigation with bland lotions in overcoming the instantaneous damage to the cornea from liquid mustard gas. Seeing that mustard gas is a "persistent" substance and that inevitably a film of oil containing dissolved gas remains on the cornea after instillation into the conjunctival sac, it does not appear desirable to use oily substances in the treatment of eye injuries from gas. This view has recently been forcibly put forward by Bonnefon (*Gaz. hebd. Sci. méd.*, 1939, **60**, 168, and *Siècle méd.*, 1939, September 1). It is, moreover, doubtful to what extent animal experiments can be applied without considerable reserve. There is some evidence that during the last war eye injuries from gas were more serious in horses than in men, and it has been suggested that the more severe course in animals might be due to the absence in them of lacrimal secretion and its defensive mechanism. On this view frequent irrigation with bland lotions or with hypertonic solutions (such as saturated solution of sodium sulphate 800 grammes, solution of glucose 200 grammes) to induce osmosis has been advocated.

Prevention of Tuberculosis

SIR,—The National Association for the Prevention of Tuberculosis has decided to devote its activities in war time chiefly to propaganda and the care and rehabilitation of tuberculous patients and their families. Tuberculosis was a grave problem during and after the last war, when the death rate rose to the level at which it had been ten years previously. Overcrowding, food shortage, and general anxiety no doubt caused this result, and the position was infinitely worse in Austria and Germany. The disease affects the military as well as the civil population, and the National Association takes the view that tuberculosis is as much a casualty of war as a wound.

The National Association has a large number of affiliated care committees throughout the country. It is hoped to encourage them in their work by periodical visits from an expert adviser. The position at the moment is complicated by the fact that owing to the need for vacant beds sanatoria and hospitals for the tuberculous have been evacuated of their patients, in some areas very largely. The Ministry of Health has the position under review, and statements from the Minister in Parliament give ground to hope that some beds will shortly be liberated.

The Burrow Hill Sanatorium Colony in Surrey, which has accommodation for eighty-six tuberculous youths, who receive treatment and training, will be kept open, and there are at present a few vacancies.—I am, etc.,

Tavistock House North, Tavistock Square, W.C.1, Oct. 24.
HARLEY WILLIAMS, Secretary-General.

Care of the Tuberculous in War Time

SIR,—In his letter in your issue of October 28 (p. 882) Mr. Somerville Hastings states, with reference to the London County Council, that the impression that the Public Health Department has virtually disappeared is inaccurate. In fact, "one has only to mention the Council's responsibility for the civilian sick, the maternity service, the treatment of venereal disease and tuberculosis, and for general public health to realize the extent of the work still being done at County Hall." Yet the position of the tuberculous patient, whether newly diagnosed or partially treated, is a source of concern to many of us who are called upon to give advice at the present time.

At the outbreak of the war most of the county and L.C.C. sanatoria were partially evacuated and the major proportion of the beds were left empty; it is even possible that some of these beds have already been occupied by non-tuberculous civilian sick. This action, taken during a state of national emergency, is bound to lead in due course to certain inevitable consequences. First, a large number of patients with open pulmonary tuberculosis have been dispersed among the general population, and the incidence of phthisis will therefore shortly increase. Secondly, there are much-reduced facilities for the treatment of freshly diagnosed patients, who will in many cases not be able to commence their treatment until the disease has already advanced beyond the early stage at which the prognosis is reasonably good.

While it is everywhere recognized that the Emergency Hospital Service must have plenty of beds at its disposal, it is most dangerous to the community that the supply should be drawn from the tuberculosis service. Not a single one of these beds can be spared. The control of phthisis has taken many years to reach its present state of partial accomplishment, but the slightest neglect will result in a severe setback. It is also false economy. For many years to come the nation will have to pay, both in money and in precious lives, for any present failure to maintain our hold upon the disease.—I am, etc.,

London, W.1, Oct. 28. JAMES MAXWELL.

⁂ A deputation to the Minister of Health on this subject is reported at page 922.—ED., *B.M.J.*

X-ray Examination of Militiamen

SIR,—The question of the radiographic examination of militiamen has been raised in your columns by Dr. J. V. Sparks, and has been the subject of subsequent correspondence. The last letter on this matter, from Dr. Gregory Kayne (*Journal*, October 7, p. 745), brought up several points for discussion. I have waited in vain hoping that Dr. Sparks's abler pen would reply to these, but now, *faute de mieux*, I am writing myself.

The first and most important matter is that of the so-called miniature radiography, which Dr. Kayne asserts to be "still on trial and considered as unreliable by several authorities." This may be so, but it is also considered quite reliable by many other authorities. Personally I was unconvinced of the utility of this method until I had worked at it myself, but I am now sure that it should occupy a well-deserved and recognized place in our public health armamentarium. The result of my work was published in *Public Health* (September, 1939), where a brief résumé may be found of some of the results obtained by examining a comparatively large section of the populace.

Since publishing this paper I have been interested to learn that Messrs. Philips of Einhoven, Holland, who have very extensive factories, have used this method not only on their workmen but also on their workmen's families, with a resultant saving to the firm, after all expenses of the examination have been paid, of several thousands of pounds a year. This saving has been effected by the early detection of disease, with a resulting decrease in the amount of time spent on sick leave. I think it is not going too far to say that what is good business for a private firm in this matter must be good business for our community as a whole.

It must not be supposed that this method of examination is quite as accurate as a full-sized *x*-ray film, and the most that I claim for it is that it will pick out a large number of actual or doubtful cases that will be missed altogether by an ordinary screen examination. Such cases should be confirmed or otherwise by a routine *x*-ray examination later. It is interesting to note that the film cost for examining a thousand men by miniature radiography is approximately £2 8s. Whether some such examination should be carried out by physicians or radiologists must be a matter for local determination. Some localities have expert radiologists and not-so-expert physicians, while in others the converse may hold. Suffice it to say that there are in this country enough efficient doctors to carry out this work adequately, and to the satisfaction not only of the public health but also of the military authorities.

I apologize for my prolixity, but the subject is both extensive and, at the present time, important.—I am, etc.,

Newton Abbot, Oct. 24. A. ROBINSON THOMAS.

Treatment of Venereal Disease in the Field

SIR,—During the 1914-18 war there occurred among British troops 400,000 cases of venereal disease. These men were evacuated from their units and sent for treatment to a special V.D. hospital at the base. In consequence they were away from the field for many weeks—sometimes months. It is a matter of common knowledge that there were numerous instances of men deliberately acquiring venereal disease so as to avoid the dangers of the firing line. It is as an effort to prevent so far as possible this wastage of men that I put forward the following suggestions.

With modern methods of treatment there is no reason whatever why a man suffering from syphilis up to the end of the secondary phase, or from acute anterior gonococcal urethritis, should be evacuated from his divisional area. Such patients can be adequately treated within that area in a field ambulance, a C.C.S., or preferably by a special divisional V.D. unit consisting of an officer experienced in venereal disease and six orderlies. Such a unit might be attached to a C.C.S. It would, of course, require to be provided with the means of carrying out microscopical investigation for *T. pallidum* and the gonococcus.

For the treatment of syphilis the intravenous arsenical should be one such as stabilarsan, which is already in solution in the ampoule. A "914" powder preparation may also be used, the solvent consisting of an ampoule of sodium thiosulphate, so countering any difficulty that might arise in obtaining sterile distilled water. The arsphenamine injections should be given thrice weekly (say, on Monday, Wednesday, and Friday) in doses of 0.25, 0.30, and 0.45 gramme, making a total of 1 gramme in each seven-day period. The bismuth agent should be a liposoluble one, given intramuscularly twice weekly, the total amount of bismuth metal being not less than 0.2 gramme per week.

Though not normally an advocate of the concurrent intermittent method of therapy, I am of the opinion that in the special circumstances—treatment in the field—that method should be adopted. The schedule I suggest is:

Unit Course

Week	Arsphenamine (gramme)	Bismuth (gramme)
1	1.0	0.2
2	1.0	0.2
3	1.0	0.2
4	1.0	0.2
5	1.0	0.2
6	1.0	0.2
7	1.0	0.2
8	1.0	0.2
9	—	0.2
10	—	0.2

Eleventh to fifteenth week, patient returns to duty.
Sixteenth to twenty-fifth week, repeat unit course.
Twenty-sixth to thirtieth week, patient returns to duty.
Thirty-first to fortieth week, repeat unit course.
Forty-first to forty-fifth week, patient returns to duty.
Forty-sixth to fifty-fifth week, repeat unit course.
This is followed by serological examination every three months for two years.

The above represents adequate treatment and, when carried through, results in 100 per cent. cure rate. The man is not only rapidly rendered non-infectious, but even while he is under ambulant treatment he can in an emergency be sent, without danger to his comrades, to rejoin his unit in the line.

The proved efficiency of sulphapyridine (M & B 693) in the treatment of gonorrhoea renders the evacuation of such cases to the base quite unnecessary. The following routine, which has proved so successful at Whitechapel Clinic, can just as efficiently be carried out in the field.

Week 1: Tablets of sulphapyridine, 3 grammes daily. Posterior irrigation with potassium permanganate, 1:8,000.

Week 2: Tablets of sulphapyridine, 2 grammes daily. Posterior irrigation with potassium permanganate, 1:8,000.

If progress is satisfactory—no urethral discharge and urine clear—at the end of Week 2 stop treatment; otherwise continue treatment for Week 2 for a further seven days.

Week 3: Daily observation for three days, then tests for cure. Satisfactory results have been obtained without irrigations, but there should be no difficulty in carrying out these in the divisional area.

A certain small proportion of cases will of course develop complications due to the disease or to treatment, and these would be the only ones requiring evacuation to a special base hospital. Men on leave or proceeding to join their units in France found to be suffering from venereal disease should not be hospitalized in England or at the base, but as soon as they are non-infectious should be transferred for further treatment to their divisional area.—I am, etc.,

E. T. BURKE,
Oct. 23. Director, L.C.C. (Whitechapel) Clinic.

Organization of First-aid Posts

SIR,—Recent excellent articles in the *British Medical Journal*, the short experience of the working of these posts by medical officers attached thereto and the A.R.P. medical officers, together with the firm front shown by the B.M.A. as to the payment of doctors, raise the question, Should the Ministry of Health not now assume entire control of and responsibility for the casualty services? Why dissociate such services which during a war are intimately connected with the hospital service? While the training of first-aiders and auxiliary nurses might well be left to the local authorities (and here I would plead for a higher standard) I certainly think that the control of the casualty services is best out of the hands of local authorities. For this there are many reasons into which I need not enter. Regarding the organization of the services I submit the following points for consideration:

(1) *Training and Recruitment.* As now, but councils to have the option of conducting their own courses and examinations, with presentation of certificates.

(2) *Administration.* The A.R.P. medical officer to be commandant of all the first-aid posts, personnel, equipment, arrangement of classes, and allocation of all personnel (doctors, nurses, matrons-in-charge, first-aiders, and stretcher-bearers). His decision to be final.

(3) *Collective Training.* This should be done by the commandant with brigade officers of the B.R.C.S. and St. John Ambulance.

(4) *Medical Officers to the Posts.* These to receive the present honorarium plus a sessional fee during a raid. They are there purely for the medical and surgical skill necessary. Most of them are general practitioners and cannot give time to collective training. The commandant should have power to call others.

(5) *Nurses at Posts.* The Government allows one trained nurse only for the first-aid room. What use would one nurse be for 50 to 100 casualties at a post? If in collective training and manning of posts there are to be three shifts of eight hours each, why should one of the most important grades of helpers be so reduced? The types of casualties to be met with demand at least one nurse for each room—the first-aid, reception, and resting rooms. In each a nurse may be occupied for some time on only a few cases. If she has to be useful for the more serious ones it is essential there should be some assistant nurses, and it is desirable before chaos occurs that the Ministry should give definite permission for these. In the mobile unit at least two trained nurses are necessary for shift work.

(6) *Decision on the Spot.* I cannot agree that ambulance men should have this responsibility—that is, of deciding where the case is to go. As a rule the best men fight shy of this because they do not attend to the casualty on the spot, which is done by the first-aid party. These contain the cream of the first-aiders and their leader is a chosen man. In the absence of a doctor, a trained or assistant nurse, the leader must give the order, and in his absence No. 1 of the stretcher party.

(7) *Mobile Units.* More use of these should be made. They are cheaper than heavy expenditure on the conversion of buildings (schools, etc.).

(8) *Posts at Hospitals.* I am of the opinion these should not be at any hospital. Let the out-patient departments carry on and during any raid let them treat what casualties come.

(9) *Gas Casualties.* These should not be taken to a hospital unless special means are provided for them. Special mobile vans, equipped with a bath and spray, should be fitted up so that the gas casualties can be immediately treated on the spot and the clothes decontaminated in a solution in special bins. The vans and bins are taken to a special area afterwards for decontamination by a special squad, and the inside water tanks replenished.

(10) *Equipment.* The surgical equipment for the posts is meagre. Ether should not be used there with so many chances of danger. Morphine, nembutal, and chloroform (safe, given on lint, for analgesia) should suffice. One table to lay a patient on is absurd. It is easy and cheap to have heavy wooden props, which won't tilt, to hold the handles of stretchers so that nurses and first-aiders are not constantly on their knees to dress cases.—I am, etc.,

Oct. 17. "CASUALTY SERVICE."

Diabetes and Renal Disease

SIR,—We feel that Dr. K. E. Barlow's article on diabetes and kidney failure (*Journal*, October 14, p. 765) cannot be let pass without comment, as the conclusions drawn are so contrary to all previous experience of diabetes. He describes two cases in insufficient detail to make a full critical discussion by us possible, but certainly Case II seems to present a picture of heart failure rather than uraemia, and there is no clear evidence of diabetes; the slight abnormality in the blood-sugar curve is most likely due to previous vomiting and ketosis. Dr. Barlow's conclusion that nephrosclerosis lowers the renal threshold for glucose is the exact opposite of our own and other experience, where renal sclerosis is mostly associated with a high threshold. He further suggests by some process of reasoning obscure to us "that the mild diabetic is better off with nephritis than without it." We entirely disagree with this baseless statement because, while there is adequate means of dealing with diabetes both mild and severe, there is no means of checking the inevitable progression of nephrosclerosis.—We are, etc.,

R. D. LAWRENCE,
W. G. OAKLEY.

The Diabetic Clinic, King's College
Hospital, London, S.E.5,
Oct. 30.

Urethrography

SIR,—May I refer to the letter of Dr. Paul Cave and Dr. G. L. S. Konstam (*Journal*, October 14, p. 786), whose comments on my article on urethrography were of particular interest to me. The constant-stream technique is of value in viewing the urethral canal under the screen. This may be done with the glass syringe. Using the syringe, however, one does not always get a film of the prostatic urethra in a distended state, but one does see the prostatic urethra in outline. This gives an entirely satisfactory picture in all but a few specific cases. By a manometric method the larger amount of fluid injected, the added difficulties, and the elaboration of technique are apt to vitiate rather than improve the value of the urethrogram. Moreover, the moving stream implies a moving urethral wall, and this clouds the *x*-ray photograph.

As for the prone position, this does not in fact bring the posterior urethra any closer to the *x*-ray film. Moreover, the technique of injecting the fluid with the patient in this position requires acrobatic contortions and difficult prestidigitations to which the ordinary urologist is somewhat unaccustomed.

The use of urethrography as a method of estimation of residual urine would necessitate the initial filling of the bladder with as much, at times, as two or more pints of lipiodol. This is expensive. It would also necessitate the use of logarithmic tables to convert the inches of the shadow into the ounces of the fluid. This is inexact.—I am, etc.,

London, W.1, Oct. 26. JAMES KEMBLE.

Mental Health of Children

SIR,—Under this heading in your issue of October 28 (p. 880) a statement which is perhaps capable of misinterpretation was made with regard to the Children's Department of the Tavistock Clinic. We should be grateful if you would allow us to point out that the practice of the Tavistock Clinic, in both the adults' and children's departments, does not now vary from pre-war days. We believe that it is therapeutically sound for everyone to pay what he can for treatment, and, where possible, we ask patients to pay a minimum fee of 3s. for a treatment interview. Under war conditions this policy is unchanged.

The risk of confusion arises from the fact that during war time a group of psychotherapists are separately carrying out private work in the same building at ordinary consulting fees. —I am, etc.,

A. T. MACBETH WILSON, M.B., Ch.B.,
Acting Medical Director.

The Tavistock Clinic, Westfield College,
Kidderpore Avenue, Hampstead,
N.W.3, Oct. 30.

Universities and Colleges

UNIVERSITY OF OXFORD

The clinical sub-dean of the Medical School, Oxford, announces that the quota of foreign refugee doctors at the Radcliffe Infirmary is now full, and that no further applications can be considered at present.

UNIVERSITY OF CAMBRIDGE

Diploma in Medical Radiology and Electrology

Owing to the national emergency it has been decided to shorten the present course from nine to six months and to hold examinations on the following dates: Part I, December 19, 1939, and April 10, 1940; Part II, April 9, 1940, and July 9, 1940. There will be no examinations for Part I in February and July, nor for Part II in October, 1940.

UNIVERSITY OF LONDON

BRITISH POSTGRADUATE MEDICAL SCHOOL

The following candidates have been approved at the examination indicated:

ACADEMIC POSTGRADUATE DIPLOMA IN CLINICAL PATHOLOGY.—Alice Benjamin, J. S. B. Bray, J. J. Dubash, S. Sivasankara Pillai.

On September 28 the degree of D.Sc. was awarded to T. C. Angus (London School of Hygiene and Tropical Medicine).

ROYAL COLLEGE OF PHYSICIANS OF LONDON

At a meeting of the Royal College of Physicians of London, held on October 26, with the President, Sir Robert Hutchison, in the chair, Dr. H. L. Tidy and Sir Adolphe Abrahams were re-elected members of the Committee of Management, Sir Comyns Berkeley a representative on the Central Midwives Board, and Sir William Willcox a member of the Poisons Board.

Licences

Licences to practise were conferred upon the following 297 candidates (including thirty-nine women) who have passed the final examination in medicine, surgery, and midwifery of the Conjoint Board, and have complied with the necessary by-laws:

F. Abadir, J. J. Ll. Ablett, A. J. Abraham, G. H. Adams, P. S. Adler, C. D. Alergant, L. L. Alexander, O. P. Allcock, R. H. Anthony, F. R. Aston, F. A. S. Austen, R. C. Baird, H. M. Balfour, D. A. Barley, Rotha H. Barnfield, T. E. Barwell, G. A. Beck, A. L. T. Beddoe, Eileen M. Benison, G. Beven, A. Bloom, D. W. Boatman, D. C. Bodenham, Norah H. Bore, C. F. Bose, A. R. Bradley, J. B. Bramwell, O. B. Brears, M. O. Brigstocke, C. A. Brockbank, B. N. Brooke, H. P. Brown, P. P. Brown, C. E. Brownridge, M. R. Bull, W. W. Burnett, Phyllis Burvill-Holmes, Alice M. F. Butterworth, R. F. Butterworth, J. G. Byrne, E. M. Calvey, P. S. G. Campbell, B. E. Camus, R. U. Carr, R. A. M. Case, J. E. Cawthorne, C. A. Cheatle, A. A. Clay, L. G. Clayton, W. T. K. Cody, P. C. Collinson, Beatrice Colvin, Ruth M. Colyer, R. S. Cox, Mary Crago, R. Crawford, G. D. Cribb, J. D. Cronin, T. H. Cullen, K. Damodaran, H. A. Davidson, E. R. Davies, F. W. T. Davies, J. N. P. Davies, W. O. Davies, R. L. G. Dawson, Ina J. Dennis, F. A. Denz, P. J. De Vescovi, R. A. B. Dickson, J. W. Doupe, J. R. Dow, Margaret S. Drinnan, M. B. Dworkis, H. Dyson, J. E. G. Earle, A. K. Eastwood, D. A. J. Ebrill, H. D. Eddy, P. K. D. Edmunds, Evelyn M. Eldrid, E. L. Ellis, H. V. W. Elwell, J. R. Elwell, T. D. V. England, A. E. J. Etheridge, M. O. Evans, I. S. Eve, Enid J. Fair, B. E. Finch, D. Feldman, F. J. Fish, G. R. Fisk, Joan M. Foss, A. J. Freese, Lilias M. P. Gairdner, Gwladys Garfield, I. B. Gartside, M. R. Gaster, P. H. G. Gell, E. Gibbon, F. J. Gillingham, C. V. Gledhill, J. Gluckman, N. H. H. Golledge, L. C. L. Gonet, D. J. H. Goodhew, J. H. Gould, G. H. Grant, M. J. Greenberg, B. G. Gretton-Watson, G. C. Griffiths, R. G. Griffiths, J. A. G. Gulliford, C. ROYAL COLLEGE OF SURGEONS OF ENGLAND

Reopening of the Museum

The general anatomical and pathological collections will be open for inspection as from Monday, November 6, at the following times: Mondays to Fridays, 10 a.m. to dusk; Saturdays, 10 a.m. to 1 p.m.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

At the quarterly meeting of the Council, held in the College House, London, W., on October 28, with the President, Professor W. Fletcher Shaw, in the chair, Walter William Chipman, M.D., F.R.C.S.Ed., F.A.C.S., F.R.C.S.(Can.), LL.D., Emeritus Professor of Obstetrics and Gynaecology, McGill University, Canada, was admitted to the Honorary Fellowship of the College (*in absentia*).

M. Datnow, Liverpool, was admitted to the Fellowship (*in absentia*).

The following were admitted to the Membership (*in absentia*):

B. H. Anderson (Melbourne), A. W. Andison (Canada), G. W. Blomfield (Leeds), D. R. Cairns (London), W. D. A. Callam (Edinburgh), D. G. W. Clyne (London), Molly C. Devenish-Meares (Sydney), D. S. Greig (London), T. N. Hart (Bolton), W. Hawksworth (New Zealand), W. M. Lemmon (Melbourne), G. G. Lennon (Birmingham), F. H. Lord (Melbourne), R. Lyons (Canada), T. A. MacFarland (New Zealand), D. M. W. Maxwell (Windsor), S. Misra (Calcutta), D. V. Morris (Galway), R. I. Ritchie (New Zealand), T. F. Rose (Sydney), Everell M. Shippam (London), R. de Soldenhoff (Lyme Regis), G. B. Thomas (Lahore), S. L. Townsend (Melbourne), J. D. Watt (Romford), Ella Windeyer.

Grace Johnston Cuthbert, Sydney, was elected to the Membership.

Mr. J. P. Hedley assumed the office of honorary treasurer in place of Mr. Eardley Holland.

The examinations for the M.R.C.O.G. and the D.R.C.O.G. will continue to be held, and the activities of the College are being maintained.

The following have been awarded the Diploma of the College:

J. J. Carter (Co. Down), Penuel M. E. Chitty (London), S. Bender (Liverpool), J. V. Dhurandhar (Bombay), Phillis Dingle (Liverpool), K. W. Evans (Liverpool), W. W. Gilford (Reading), G. Gillies (Burton-on-Trent), W. Heng (Hong Kong), J. R. E. James (Carmarthen), J. E. Jameson (Moreton-in-Marsh), V. N. Khadilkar (Bombay), O. P. D. Lawson (Bellshill), S. Madden (Leeds), J. M. McKiddie (Aberdeen), K. S. E. MacRae (Liverpool), Mabel G. Miller (Manchester), Anne C. Robertson (Hull), I. Rose (Barnsley), K. C. Shah (Bombay), P. N. Simons (Sydney), I. E. J. Thomas (London), R. M. Williams (London), J. W. E. Webster (Aberdeen), L. A. C. Wood (Penshurst).

SOCIETY OF APOTHECARIES OF LONDON

Mastery of Midwifery Examination

In view of the present unsettled conditions the examination for the Mastery of Midwifery will not be held in November this year. The examination next May will be held as usual if circumstances permit. Regulations and forms of application for admission to the examination may be obtained from the Registrar, Society of Apothecaries of London, Water Lane, Queen Victoria Street, E.C.4.

The following candidates have passed in the subjects indicated:

SURGERY.—B. Berman, J. J. Brenner, W. R. Dyke, R. G. Feast, M. C. Fulton, E. F. Gleadow, M. C. Mair, S. T. Nakib, G. L. L. Reynolds, E. G. F. Skinner, D. Specter, J. A. Sutton.

MEDICINE.—W. R. Dyke, M. C. Fulton, G. Hannigan, S. Krishnan, J. Marks, T. Owen, T. I. Palmer, W. E. Roden, J. C. Scott, H. F. Sparling, E. A. Spouse, W. N. Vellacott, C. E. Winterstein.

FORENSIC MEDICINE.—W. R. Dyke, M. C. Fulton, G. Hannigan, J. Marks, T. Owen, W. E. Roden, J. C. Scott, H. F. Sparling, E. A. Spouse, W. N. Vellacott, C. E. Winterstein.

MIDWIFERY.—T. A. H. Adkins, M. E. Davies, W. R. Dyke, A. A. M. Easton, G. E. H. Enderby, M. C. Fulton, R. H. Gaman, P. Haden, A. Hannun. W. D. Jenkins, H. A. Kreiser, A. P. Motley, S. J. P. Ras.

The diploma of the Society has been granted to J. J. Brenner, M. E. Davies, W. R. Dyke, M. C. Fulton, W. D. Jenkins, S. Krishnan, M. C. Mair, A. P. Motley, S. T. Nakib, T. Owen, T. I. Palmer, G. L. L. Reynolds, W. E. Roden, H. F. Sparling, D. Specter, W. N. Vellacott, C. E. Winterstein.

The Services

HONORARY PHYSICIAN TO THE KING

The King has approved the appointment of Colonel G. G. Jolly, C.I.E., V.H.S., I.M.S., to be Honorary Physician to the King as from August 17, 1939, in succession to Brevet Colonel R. N. Chopra, C.I.E., I.M.S., who has retired.

HONORARY SURGEON TO THE KING

The King has approved the appointment of Colonel J. Taylor, C.I.E., D.S.O., V.H.S., I.M.S., to be Honorary Surgeon to the King as from August 30, 1939, in succession to Colonel Sir Alexander J. H. Russell, C.B.E., I.M.S., who has retired.

DEATHS IN THE SERVICES

Lieutenant-Colonel CHARLES WALTER HOLDEN, C.M.G., D.S.O., R.A.M.C. (ret.), who died at Sheffield, aged 60, was educated in the school of the Royal College of Surgeons in Ireland, and took the L.R.C.P. and S.I. in 1900, and subsequently the D.P.H. of the Irish Colleges and the D.T.M. and H. at Cambridge. After qualifying he filled the post of resident physician at the Whitworth Hospital, Dublin. He entered the R.A.M.C. as lieutenant on January 31, 1903, became major on September 1, 1914, and received a brevet lieutenant-colonelcy on June 3, 1918, retiring on May 15, 1926. He served as civil surgeon in South Africa from March, 1901, to February, 1902, taking part in operations in Cape Colony, and received the Queen's medal with three clasps; and in the war of 1914-18, when he was mentioned in dispatches. He was a member of the British Medical Association for twenty-seven years.

Obituary

SIR PATRICK HANDYSIDE

Surgeon Rear-Admiral Sir Patrick Brodie Handyside, K.B.E., C.B., whose distinguished service career was recorded briefly in our last issue at page 890, was born in 1860, a son of John Brodie Handyside of Fenton, Drem, who for many years, and also his father before him, farmed West Fenton. Educated at Edinburgh Academy, Patrick Handyside studied medicine at the University of Edinburgh, and after graduation was appointed assistant surgeon in the Royal Navy in 1884, shortly after his twenty-fourth birthday. In 1903 he was promoted fleet surgeon "for conspicuous professional merit," and his subsequent rapid advancement to the rank of Surgeon General was largely due to recognition of his sound professional knowledge and administrative ability. His inquiries into the health of the Japanese Navy and Army, both in Manchuria and Japan, earned him public appreciation from the British and Japanese Governments. Sir Patrick's oversea service included the North America and West Indies station, Cape of Good Hope, Esquimalt Hospital, and China. His service in this country was largely spent in appointments at the Royal Naval Hospitals at Plymouth and Chatham, and from the latter hospital he retired in 1920 with the rank of surgeon rear-admiral. His retirement to Gullane did not end the activities of a full and vigorous life; he was deeply concerned for the well-being of ex-service men and accepted office as honorary president of the Gullane Branch of the British Legion. He also interested himself in local politics and was a member of the East Lothian County Council. The funeral took place privately in Edinburgh.

JOHN ELLISON, F.R.C.S.Ed., F.R.C.O.G.

Surgeon, Chelsea Hospital for Women

We regret to announce the death on October 19 of Mr. John Ellison, the well-known gynaecologist, who was for many years a member of the visiting staff of the Chelsea Hospital for Women.

Born at Jullundur in 1886, he was educated at All Hallows School, Honiton, and Downing College, Cambridge, graduating B.A. in 1909 and taking the M.B. and B.Ch. degrees in 1912. His early appointments were those of house-surgeon, resident obstetric assistant and gynaecological registrar at St. George's Hospital, where he had won a university scholarship from Cambridge. Deciding to devote himself to diseases of women, he served as registrar at the Samaritan Free Hospital, at the General Lying-in Hospital, and at the Chelsea Hospital for Women, and after taking the F.R.C.S.Ed. in 1918 he was elected assistant gynaecological surgeon to the Grosvenor Hospital for Women, and surgeon to out-patients at Chelsea. Later he became consulting gynaecological surgeon to the Watford Peace Memorial Hospital, the Woodford Jubilee Hospital, the Chislehurst, Orpington, and Gray Valley Hospital, and the Bute Hospital, Luton; he was also consulting surgeon for puerperal fever to the Counties of Hertford and Bedford. He joined the British Medical Association in 1925 and was elected F.C.O.G. in 1934.

Mr. Victor Bonney writes: Will you allow me to pay a tribute to the memory of John Ellison, whose premature and sudden death has come as a great shock to his many friends. I was intimately associated with him at Chelsea Hospital for Women for a long period, during part of which I had the advantage of his assistance in the operating theatre. He combined a wide knowledge of the specialty he practised with sound judgment and sterling common sense. Naturally averse, I think, to anything that savoured of the spectacular, he yet as a surgeon was most fully equipped, and adorned with manipulative skill and unswerving conscientiousness an operative repertory which commanded every gynaecological procedure performed at the present day. His colleagues and all who knew him will long deplore his departure.

GEHEIMRAT DR. HANS HORST MEYER

Geh.Rat Hans Horst Meyer, whose death on October 6 is announced at the age of 86, was the chief direct inheritor and transmitter of tradition from a great era which, under Binz, Buchheim, Schmiedeberg, and Böhm, saw the foundation in Germany of pharmacology as an experimental science. Meyer was a pupil of Ludwig and of Schmiedeberg, and after a brief tenure of the Chair of Pharmacology in Dorpat, held those in Marburg and in Vienna for the main periods of his active career. His name will always be associated with the theory connecting anaesthetic activity with relative solubility in water and lipoid solvents, put forward at the same time and independently by E. Overton. Other well-known researches by Meyer dealt with the natural and artificial muscarines, and with local tetanus, the latter in association with the late F. Ransom. No list of Meyer's published researches, however, can do justice to his position and influence in pharmacology, which spread far beyond his own country. A man of distinguished and attractive personality, he made many contacts here and in America, as well as on the continent of Europe. The textbook of experimental pharmacology which he wrote with the late R. Gottlieb is a standard work kept up to date till recently with his pupil and successor, E. P. Pick, now in America. Another distinguished direct pupil of Meyer is O. Loewi, professor in Graz till 1938. At any international gathering of pharmacologists in recent years the thoughts of those present from all countries turned to Meyer, with the desire to send a message of affectionate respect to the venerable master of their science.

H. H. D.

Among the late Mr. ARTHUR THOMAS PITTS's dental appointments (writes "D. N.") there was none which gave him more pleasure and which was of greater service to the community than his long connexion with the Hospital for Sick Children, Great Ormond Street. Mr. Pitts's association with this hospital began more than thirty years ago as clinical assistant to Mr. Warwick James, who was then dental surgeon to the hospital. On Mr. James's resignation in February, 1914, Pitts was elected to succeed him, and he occupied the post for more than the usual fifteen years of active service to the hospital, for during the last war he served with great distinction during the years 1914–19. He was so interested in his work at Great Ormond Street that at the end of the normal period of service he applied to the Board of Management for an extension of the tenure of his post. This was willingly granted, and on his resignation in October, 1930, his long and valued services to the hospital were recognized by his appointment as consulting dental surgeon. Pitts was devoted to children and they to him, with the result that they willingly attended his clinics, realizing, as if by instinct, that all he did was for their benefit. Among the many aspects of dental surgery in which he was interested was the relation of oral manifestations to systemic disease in children, to the discussion of which he gave a stimulating opening address at a meeting of the Royal Society of Medicine in 1927. Congenital syphilis was among the diseases discussed, and in this disease he had long interested himself. He was a great admirer of Sir Jonathan Hutchinson and was well acquainted with all his writings on syphilis. In his dental clinics at Great Ormond Street Pitts was always on the look-out for teeth suggestive of congenital syphilis, and on many occasions his suspicions were confirmed by subsequent blood tests. It is to be hoped that his teaching on this branch of paediatrics, which is too little studied by dentists as well as doctors, will not have fallen on stony ground, and that it will be remembered and applied by his disciples and pupils. The present writer was greatly indebted to him for much valuable co-operation on a subject in which we were both interested. This help was always willingly given, and in his clear and incisive manner. His premature death is a great loss to the two professions of which he was a valued member. Our sympathy is extended to his widow, who was formerly a nurse at Great Ormond Street, and to his family.

Dr. HENRY A. ELLIS, who died at Crowborough on October 3 after a long illness, was born on July 24, 1861, the fourth son of Colonel Francis Ellis of Omagh, County Tyrone. He was educated at St. Columba's, County Tyrone, and privately at Stratford-on-Avon, and qualified at Trinity College, Dublin (M.B. 1884, B.Ch. 1885). In 1885 he went to Australia, and was a resident at Sydney Hospital for two years. From 1890 to 1894 he held the posts of honorary surgeon and physician to the hospital. For the next nine years he was medical officer of health for Western Australia and superintendent to the Government Sanatorium, Coolgardie. He played a prominent part in Australian politics during these years, sitting in Parliament from 1903 to 1906 and supporting energetically the successful movement for Federation. Returning to England in 1913, Dr. Ellis was tuberculosis officer in Middlesbrough throughout the war and a commandant of the Red Cross Society. In 1919 he came to London as assistant physician at the Margaret Street Hospital for Diseases of the Chest. He married in 1913 Emily K. Gordon Wylie, third daughter of the Rev. David Stewart Wylie of Adelaide, South Australia. Dr. Temple Grey writes: Ellis will be sorely missed in the comparatively small circle that was privileged to know him. Big in body and mind, he had an uncommonly commanding appearance. His wide experience and unconventional modes of thought with many whimsical expressions were less appreciated than they might have been except by his friends. His rare talents, little short of genius, were employed chiefly so far as medicine is concerned on the elucidation of constitutional types from a chemical point of view. His work owed its value less to his technical equipment than to his broad imagination and singular inventiveness. I have never seen or heard of such elaborate analyses of the urine as he used to make, including the estimation of the Mg, Ca, K, and Na almost as a routine. Every medical man should read his *Reaction and Disease* (Lewis), and as for his capillator for the determination of the *p*H, those who have not used it have much to learn about time-saving methods. A few of us formed with him in 1928 the Ringer Society, which used to meet on Sundays, but seven days' work a week proved too much for all of us except Ellis, and the society ceased to meet.

We regret to announce the death of Dr. JOHN KENNEDY, of High Road, Leyton, which took place at his home on October 24. Only ten days before Dr. Kennedy carried out his professional duties, although suffering with angina pectoris, from which malady he succumbed. Born in Coatbridge sixty-two years ago, he was educated at Glasgow University. After graduating M.B., Ch.B. in 1902 he held posts at the Glasgow Royal Infirmary as house-surgeon and house-physician, and subsequently was resident assistant physician at the Ruchill Fever Hospital, Glasgow. He came to Leyton thirty-two years ago and took over a large practice in the heart of the town. He had been a well-known and popular figure in the life of

Leyton for a whole generation. He was district medical officer for the Essex County Council, and emergency medical attendant to the Leyton Isolation Hospital. He was a member of the British Medical Association since 1911, a Freemason of the Coatbridge Lodge, and a member of the Chingford Golf Club. He leaves a widow and two sons, for whom much sympathy is felt, and is survived by his aged parents and sister, who live at Bothwell, and by his brother, Dr. Alexander Mills Kennedy, physician to the Cardiff Royal Infirmary. The funeral took place on October 27 at the City of London Cemetery.

Mr. Philip Northcott Vellacott, formerly of Bloemfontein, died on October 24, at Crowborough. A student of Guy's Hospital, he graduated M.B.Lond. with honours in obstetric medicine in 1895, took the English Conjoint diplomas in 1896, and the B.S. in 1897. For a time he was captain in the Orange River Colony Division of the South African Constabulary, and in 1901 obtained the F.R.C.S.Eng. In 1908 he contributed an article on hydatid disease to the *South African Medical Record*. Mr. Vellacott was vice-president of the Orange Free State Branch of the British Medical Association in 1914–15 and 1922 and president in 1924–5 and 1932–3. During the last war he held a commission as temporary Major R.A.M.C. in the British Expeditionary Force.

News has been received of the death at his home in Claremont, Capetown, of Mr. Arthur Ronald McLachlan, who was honorary surgeon to the Woodstock Hospital, Capetown, and additional honorary surgeon to the New Somerset Hospital, Capetown. After studying medicine at Guy's Hospital and taking the English Conjoint diplomas in 1899 he obtained the F.R.C.S.Eng. in 1901, and served as civil surgeon in the South African Field Force. Mr. McLachlan joined the British Medical Association in 1904 and was chairman of the Capetown Division in 1932.

The late Professor Santesson, who died from coronary thrombosis on July 26 in Sweden, held at one time the chair of pharmacology in Stockholm. Even after his retirement from this post he led an active life, and he published altogether more than 200 scientific studies. Some of them dealt with the pharmacology of digitalis and allied drugs.

The following well-known foreign medical men have died: Dr. Ralph Augustus McDonnell, formerly clinical professor of dermatology, Yale University School of Medicine; Dr. Axel E. Bisgaard, a Copenhagen psychiatrist, aged 64; Dr. Henri Blanc, former president of the Société des Chirurgiens de Paris; Dr. Hans Sauer, one of the pioneers of Kimberley, the Rand, and Rhodesia, and one of the first medical officers of health in South Africa, and author of an autobiographical work entitled *Ex Africa;* and Dr. Félix Legueu, emeritus professor of urology in the Paris faculty, aged 72.

Medical Notes in Parliament

This week the House of Commons completed its consideration of the Prices of Goods Bill. It also discussed a proposal to increase old age pensions, the problems of civil evacuation, and the effect of certain Defence Regulations on the liberty of the subject.

The Parliamentary Medical Committee met on October 26. Sir Francis Fremantle reported on consultations with Ministers about medical questions in the emergency.

Sir Ernest Graham-Little has invited members representing university constituencies to form a committee.

Emergency Medical Service

Sir Ernest Graham-Little inquired on October 25 what schemes of emergency medical service for the members of visiting staffs of voluntary hospitals in London were now official and open for acceptance by those members; and whether Dr. Elliot would take measures to encourage the return of visiting staffs to London, and the opening of the beds in hospitals for civilian cases, with a view to restoring some adequate instruction for medical students for whose education the London teaching hospitals were chiefly responsible. Dr. Elliot, in reply, stated that after the enrolment of whole-time officers in the Emergency Medical Service two modifications were introduced—one enabling these officers to go on indefinite leave without pay until the occurrence of casualties made it necessary to recall them to duty, and the other, which was recommended by a committee of representative consultants, enabling these officers to transfer from whole-time to part-time service. The second offer was made by letter to individual whole-time officers in the Emergency Medical Service, and officers proposing to accept the offer were asked to do so within a week. He was, however, willing for the present to continue to keep the offer open to those officers who had not yet replied. He was also in consultation with the Presidents of the Royal Colleges of Physicians, of Surgeons, and of Obstetricians and Gynaecologists, and others on a number of points arising out of experience of war conditions so far. He understood that he might receive shortly further proposals from a representative committee of the profession now sitting, which he would consider in connexion with the points raised by Sir Ernest. Dr. Elliot added that he would have no objection to a further arrangement under which certain senior men of the standing of Fellows of the Royal College of Physicians not already in the Service who were willing to give a substantial proportion of their time if a major emergency arose but were desirous, in present circumstances, of remaining without obligation and without remuneration, would so inform him. It had been made clear to hospitals by broadcast announcements and otherwise that civilians requiring in-patient treatment should be admitted. He had at all times been anxious, in consultation with the profession, to adopt such measures for making the necessary medical staff available as were consistent with due provision for the treatment of air raid casualties.

Mr. Spens asked Dr. Elliot on October 26 to what extent he found it possible to consult the medical profession in determining the terms and conditions of employment of medical practitioners in the Emergency Medical Service. Dr. Elliot replied that consultations with representatives of the medical profession had taken place at frequent intervals. In 1937 the Central Emergency Committee of the British Medical Association was asked to compile a register of practitioners with a view to ascertaining their availability and special qualifications for service in an emergency. This register comprised about 98 per cent. of the profession. The utmost use was made of this committee (now called the Central Medical War Committee), working through local committees which were representative of the profession as a whole. The grading and basis of organization of the Emergency Medical Service followed the recommendations of the Central Medical War Committee and the Group Officers, who were eminent consultants. In July, 1939, invitations to enrol for whole-time service were sent to practitioners who were nominated by the Group Officers. Arrangements were subsequently made under which these full-time officers could go on indefinite leave without pay, subject to recall when occasion arose. Later, the option to transfer from full-time to part-time service was given under conditions recommended by a committee constituted from among leaders of the profession and presided over by Sir Bernard Docker. The constitution of this committee and the conditions it recommended were given in reply to Sir Ralph Glyn on October 12. On October 18 a committee consisting of the Presidents of the Royal Colleges of Physicians, of Surgeons, and of Obstetricians and Gynaecologists, and representatives of the Group Officers, of the Central Medical War Committee, and of the London County Council was set up to consider whether present circumstances necessitated further measures of reorganization. This committee had not yet reported.

Dr. Elliot circulated details of the personnel of the Central Emergency Committee (Central Medical War Committee), the Group Officers, and the special committee appointed on October 18, and these are published in the *Supplement* this week at page 216.

inoculated against small-pox. Dr. Elliot said in reply on October 25 that the consideration whether a child had or had not been vaccinated was not at present one which the local authority was required to consider in arranging billets for evacuated children. In present circumstances the risk involved need not be taken into account.

Mr. Viant asked on October 26 if Dr. Elliot's attention had been directed to a statement made by the medical officer of health to the Launceston Town Council that he had been advised by the Minister of Health that the consent of the teacher in charge of evacuated children to his proposal to inoculate them against diphtheria would be sufficient. Dr. Elliot said his attention had not been drawn to this statement, and he could not understand how it could have been made. It would be quite contrary to the policy and instructions of his Department for evacuated children to be immunized against diphtheria without the previous consent of their parents.

Local Authorities and Treatment of War Casualties.—Dr. Elliot announced on October 19 that he had informed local authorities and other similar bodies that the reasonable cost of treating and maintaining casualties in hospitals and generally any additional expenditure due to the participation of hospital authorities in the Emergency Hospital Scheme would be met by the Exchequer. He had forwarded to the representative associations of the local authorities concerned certain proposals as a basis upon which interim payments from the Exchequer should be made. He hoped to announce the arrangements at an early date.

Vaccination and Inoculation in the Army.—On October 24 Mr. Hore-Belisha told Mr. Leach that definite instructions had been issued to all army commands to the effect that inoculation and vaccination were on a purely voluntary basis.

Sir Victor Warrender stated on October 19 that soldiers were required to rest for forty-eight hours after anti-typhoid inoculation. Only exceptionally had this period of rest to be extended. Sick leave was unnecessary. Untoward effects were unusual and, if they occurred, were transient.

Unsuitable Children's Camps in Suffolk.—Mr. Sorensen drew attention on October 26 to complaints concerning cold, lack of light, inadequate air raid precautions, and general unsuitability of conditions affecting defective children evacuated from Leyton and elsewhere to Suffolk coast camps. Mr. Kenneth Lindsay replied that the camps in question were inspected early in the summer by representatives of the evacuation authority for London, and appeared to be the most suitable accommodation which could be found for handicapped children. After expert inspection a number of these camps had not been found suitable for continued use by such children in winter conditions, and five had been vacated. It would probably be necessary to vacate two further camps.

Alien Medical Graduations at Edinburgh.—Sir John Anderson announced on October 26 that he would have inquiries made and collect particulars of the cases of the sixteen graduates of foreign universities who had recently been admitted licentiates of the Royal College of Physicians of Edinburgh. He had not obtained information to show whether it was intended to allow them to practise medicine or surgery in Great Britain or in other parts of the British Empire.

Death Rates.—Mr. Colville, replying to Mr. R. Gibson on October 31, said that except in the case of the largest towns, wide variations in the weekly death rates of individual towns were a normal experience. If the death rates in Greenock and Hamilton were examined over the first six months of this year it would be found that, although there were marked differences in the weekly rates between the one town and the other, the aggregate death rates over that period for each town and for the large burghs of Scotland as a whole were practically the same.

Cheap Milk Scheme.—Seventy-eight welfare authorities have submitted proposals for the supply of cheap milk for mothers and young children, 122 have stated that the matter is under consideration, 171 have not yet replied, and thirty-six have deferred consideration.

Notes in Brief

The distribution of anti-gas protective devices for young children is under review. Where additional quantities are required to meet the needs of evacuated children who have returned home these will be supplied.

Mr. Chamberlain hopes next week to be able to make a statement with regard to the further consideration of the Criminal Justice Bill in the House of Commons.

The standard margarine will contain additions of vitamins A and D, estimated to bring it up to the vitamin value of butter.

Allocation of raw materials for the glucose industry is under consideration, and the Government is aware of the demand for pure glucose for medicinal purposes and for the manufacture of infant foods.

Medical News

The Delhi correspondent of the *Times* states that H.H. the Maharaja of Gondal has sent the Viceroy of India a cheque for 100,000 rupees (£7,500), requesting that this sum be distributed among the dependants of the men who lost their lives through the sinking of the *Royal Oak*. The Maharaja is an M.D. and F.R.C.P. of Edinburgh, having graduated in medicine in 1892, and a Fellow of the College of Physicians and Surgeons of Bombay. He has received the high honours of G.C.S.I. and G.C.I.E. from the King-Emperor, and the LL.D. and D.C.L. from the Universities of Edinburgh and Oxford.

The B.B.C. announces that talks on health matters will be broadcast as follows: November 9, 4.15 p.m., "Talking it Over: Your Health," by a Harley Street physician; November 10, 9.45 a.m., and November 17, 10 a.m., "Family Life," by a medical psychologist.

By reason of the war it has been decided to shorten the course for the Cambridge Diploma in Medical Radiology and Electrology from nine to six months, and to hold examinations for Part I in December and April next, and Part II in April and July. Details will be found under "Universities and Colleges."

Owing to the war it has been decided by the council to suspend all activities of the Chelsea Clinical Society.

The King has approved the award of a silver clasp inscribed "Antarctic 1935–37" to Surgeon Commander Edward William Bingham, R.N., a member of the British Graham Land Expedition, 1935–7.

Manchester Royal Infirmary received permission on October 30 from the Ministry of Health to reopen the twenty-eight beds at the central branch in Roby Street and the 134 beds at Barnes Convalescent Hospital, Cheadle, where a new operating theatre has been installed.

At a recent meeting of representatives of the Leeds City Council, the West Riding Council, and the hospitals of Leeds, held at the General Infirmary, it was decided to increase substantially the number of beds available for civilian sick in some of the hospitals of the Leeds group. The Health Committee of the Leeds Corporation had previously decided to release for civilian sick about a hundred beds out of the eight or nine hundred for war casualties.

National Rat Week begins this year on November 6. A leaflet "The Destruction of Rats and Mice" is issued free on application to the Ministry of Agriculture.

On October 31 Mr. GROVES asked the Minister of Health if he was aware that many medical men appointed to the emergency medical services had been dismissed, and that those in Class G would receive, by way of compensation for such dismissal, a payment equal to salary at the rate of £350; and if he would state by whom such appointments were made. Dr. ELLIOT said that no medical men appointed to the Emergency Medical Service controlled by him had been dismissed, and no question of compensation therefore arose. Class G consisted of resident house officers who were appointed for three months or longer at £350 a year, this being the scale of salary recommended by the Central Medical War Committee on behalf of the profession.

Heavy Vehicles as Ambulances

On October 31 Mr. WOODBURN asked the Minister of Health whether he was aware of the apprehension in the medical profession about the present practice of adapting heavy motor vehicles as ambulances for the conveyance of war-time casualties; that a number of medical officers of health and air raid precautions authorities had condemned these vehicles as unsuitable for the purpose intended, that the cost of compensation and the cost of adaptation of these heavy vehicles was greater than the capital cost involved in the purchase of new trailer ambulances; and whether he would give instructions to permit trailer ambulances to supplant unsuitable motor vehicles and relieve these for the needs of road transport. Miss HORSBRUGH said she was aware that some of the vehicles on which local authorities had had to rely for ambulances at the outset of the emergency required to be replaced by more suitable vehicles. It was desirable, on grounds of economy, to eliminate so far as possible the cost of hiring commercial vehicles for the ambulance service, and the Minister had recently authorized local authorities to purchase vehicles, but not necessarily trailers, in substitution for hired vehicles.

Panel Doctor's Payments

On October 24 Mr. GROVES asked the Minister of Health when and why the departmental circular was sent to insurance committees suggesting that only two-thirds of the sums due to insurance practitioners for last quarter should be distributed. Dr. ELLIOT replied that the circular was sent out on September 13. At the outbreak of war the departure of insurance practitioners on war service was in some cases not notified by them to insurance committees for a considerable time. The circular therefore recommended that where the position was not clear insurance committees should make payments on account representing the first two months only of the quarter, the balance being paid at the end of the present quarter or at such earlier date as might be convenient.

Recruitment of Doctors

Mr. GROVES asserted on October 25 that there was a feeling among members of the medical profession of victimization in connexion with the selection of personnel for the examination of recruits. He asked Mr. Ernest Brown whether he would collaborate with all associations of doctors to ensure equity. Mr. ERNEST BROWN replied that he was not aware of any ground for the alleged feeling of dissatisfaction among members of the profession.

Mr. GROVES inquired on October 26 whether Dr. Elliot had approached the Union of Medical Practitioners in respect of the supply of medical men for the forces and for the examination of recruits; and whether he would accept the services of this organization, which was available for co-operation with the Government. Dr. ELLIOT said in reply that the register of medical men available for the duties indicated was kept by the Central Medical War Committee, which, with its local committees, was widely representative of the profession. While, therefore, he appreciated the desire of the Union to co-operate, he could not usefully avail himself of its services for the two purposes suggested.

Answering supplementary questions by Mr. Groves, Dr. ELLIOT said he had always done his best to co-operate with the trade union movement, but this was a case of different organizations, and there was difficulty in negotiating with both. The Central Medical Register collected the names of 98 per cent. of the profession, and in any organization that would be regarded as a good register.

Measles: Precautionary Measures in Reception Areas

Mr. ISAACS asked the Minister of Health on October 25 whether any steps had been taken in the reception areas to deal with the anticipated measles epidemic which, over some period past, has occurred regularly every two years. Dr. ELLIOT replied that he had drawn the attention of local authorities to the need for additional hospital accommodation in reception areas for cases of infectious diseases both notifiable and non-notifiable. He was also issuing regulations providing for the compulsory notification of measles and instructing medical officers of health to make such inquiries and take such steps as were necessary or desirable for investigating the source of infection, for preventing the spread of infection, and for removing conditions favourable to infection.

Effect of Aircraft Engine Noise

Sir FRANCIS FREMANTLE asked on October 25 what action Sir Kingsley Wood had taken to reduce deafness from engine noise in the aviators and mechanics of his Department, and to ascertain and train the deafened for further service; and whether he would obtain the co-operation of the National Institute for the Deaf in the matter. Sir KINGSLEY WOOD replied that devices to lessen the effect of aircraft noise were provided for all flying personnel. Research into the question continued. Nerve deafness due to engine noise affected the hearing to a minor degree only and, as cases were detected at an early stage, did not ordinarily result in incapacitation. All flying personnel were examined periodically to assess the condition of their special sense organs, including the ears.

Doctors at First-aid Posts

Mr. GROVES asked if Dr. Elliot knew of the growing discontent of doctors in relation to the unsatisfactory arrangements made in connexion with first-aid posts by reason of their frequent attendance for the purpose of ensuring efficiency should an emergency arise, and of the fact that they did not know whether they were to be remunerated or were expected to do such work voluntarily. Dr. ELLIOT on October 25 replied that he recently discussed with representative doctors attached to first-aid posts the arrangements already made for training the personnel attached to the posts and the remuneration to which they were entitled under those arrangements. He recognized that some revision of the plan might be required owing to the course which the war had taken up to the present. He was considering the representations made in the light of reports which he had asked his officers to make on the situation in various parts of the country.

Mr. WOODBURN asked on October 26 why doctors attached to first-aid posts were not supplied with service gas-masks, steel helmets, and protective clothing; and if Dr. Elliot would have this deficiency remedied forthwith. Dr. ELLIOT said arrangements had been made to supply doctors attached to all first-aid posts with civilian duty respirators. An issue of light protective clothing had been made to every post. As regards steel helmets, arrangements had been made to supply them to doctors attached to mobile first-aid posts. Those arrangements were being extended to other first-aid posts. It was not considered necessary to supply general service respirators for this type of work. In a further question Mr. Woodburn challenged Dr. Elliot's statement that there was an issue of proper protective clothing to all posts, and said that many doctors had been sent civilian gas-masks.

Evacuated Children: Small-pox and Diphtheria Prophylaxis

Sir GIFFORD FOX asked whether householders on whom evacuated children were billeted and who themselves had children were compelled to accept evacuees who had not been

A cable has recently been received in London from Monte Video quoting a declaration by the Medical Syndicate of Uruguay, which states that in view of the events taking place in Europe the Syndicate wishes once more to record its repudiation of wars of conquest, and expresses its spiritual solidarity with the democratic countries which resist the use of force as a means of subjugating weaker nations.

The issue of the *Schweizerische Medizinische Wochenschrift* for October 7 is devoted to experiments on living animals, and contains articles by such well-known authorities as A. von Muralt and H. Hediger of Berne, W. R. Hess, Hans Fischer, H. Mooser, W. Free, and H. Binswangen of Zurich, Etienne Burnet of Tunis, R. Dujarric de la Rivière of Paris, Paul Uhlenhuth of Freiburg i. B., H. Roch of Geneva, Rudolf Staehelin of Basle, followed by an account of the anti-vivisection movement in England.

According to *Minerva Medica* of September 1, the only female surgeon in Germany is Frl. Caterina Freyberg of the Olga Hospital of Düsseldorf. She was the first medical student in Germany, and carried out her studies at Bonn. During the last war she directed a field hospital at Charleroi and a military hospital at Lenz. Since then other German women have qualified in medicine, but she remains the only surgeon.

According to *Policlinico* (Sez. Prat.), October 16, every soldier in Germany has his blood group noted in his identification book.

The issue of *Paris Médical* for October 7–14, which is devoted to neurology, contains articles by A. Baudoin and H. Schaeffer on neurology in 1939, the diagnosis of infantile paralysis by L. Babonneix, and the retrogression of infantile encephalitis by A. Tournay; and an obituary notice of Professor Marcel Labbé.

Professor H. C. Souja-Aranjo, member of the Brazilian Academy of Medicine and vice-president of the International Leprosy Commission, has founded two prizes at the Academy, each of the value of 2,000 dollars—namely, the Kadrowsky prize for the best work on the bacteriology of leprosy, and the Lieras Acosta prize for the best work on the immunology of leprosy.

A revised list (No. 7) has been issued by the Ministry of Health of treatment centres approved by the Minister under the Public Health (Venereal Diseases) Regulations, 1916, with particulars as to the days and hours for medical examination and treatment, and for intermediate treatment by or under the supervision of nurses or male attendants. A list of hostels and other institutions for women which accept in-patients under the approved schemes of local authorities for the treatment of venereal diseases is appended to the document.

Sir William Bragg, President of the Royal Society, has issued an appeal for funds for the Anglo-French Ambulance Corps, of whose general committee he is chairman. The personnel of the ambulance would be recruited from British residents in France. The honorary secretary's address is 42, Ennismore Gardens, London, S.W.7.

Dr. Robert Doerr, professor of hygiene at the Basle faculty of medicine, has been made a doctor *honoris causa* in natural science in his university in recognition of his work on ultra-virus diseases, especially psittacosis, and the relations between herpetic virus and encephalitis.

According to *Policlinico,* the mortality in the large cities of Germany from senile diseases such as cancer, diabetes, apoplexy, heart disease, and senile decay has recently shown an increase. As regards the infectious diseases of children, there has been a considerable increase in the first quarter of 1939 in the mortality of measles, scarlet fever, and whooping-cough, while that of diphtheria has fallen.

The following Italian professors have retired on reaching the age limit: Roberto Alessandri of Rome (surgery), Filippo Botazzi of Naples (physiology), Arturo Donaggio of Bologna (nervous and mental diseases), Ersilio Ferroni of Florence (obstetrics), and Ferdinand Levine of Milan (human anatomy).

Sofia University, which celebrates its fiftieth anniversary this year, has had a faculty of medicine only since 1918. At present there are 2,900 medical practitioners in Bulgaria, the ratio to the population being 1:2,000, compared with 1:5,090 in 1924. There is a plethora of doctors in the larger cities, while in the villages there is a scarcity.

The Dutch Medical Association has issued a request that all doctors in Holland should make the smallest use possible of motor fuel, and should use their motor cars only for their practice.

It has been decided that during the war no civilian doctor in Germany may change his residence without the permission of the Medical Board.

Since 1937 the following eminent Viennese doctors have been commemorated on postage stamps: Gerhard van Swieten (1700–1772), Leopold von Auenbrugger (1772–1809), Karl von Rokitansky (1804–1878), Joseph Skoda (1805–1887), Ferdinand von Hebra (1816–1887), Joseph Hyrtl (1810–1894), Theodor Billroth (1829–1894), and Theodor Meynert (1833–1892).

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

In England and Wales scarlet fever and pneumonia (influenzal and primary) have risen during the week by some 14 per cent. and 48 per cent. respectively. There is no reason to suppose that the observed increases are more than should be expected on the approach of winter; actually, notifications for Great Britain and Eire, with the exception of Northern Ireland, are below the figures for last year. Pneumonia, on the other hand, is rather more prevalent than last year; in view of the lower incidence of primary pneumonia in Scotland and the smaller number of deaths from this disease in England and Wales, it is probable that influenza or febrile catarrhs complicated by bronchopneumonia are mainly responsible. Clinical reports suggest that colds and catarrhs rather than influenza are the prevalent infections at present.

Compared with last year, notifications of diphtheria have slumped considerably in all the countries except Northern Ireland. In London, as in other large cities, epidemic diseases, especially those in which attack falls principally on children, represent only a fraction of last year's levels. Enteric fever, which attacks adolescents and adults chiefly, shows a slight increase over last week and a decided increase over last year. Four counties accounted for more than half the total for England and Wales—namely, Chester, 10 (Birkenhead 5, Wallasey 2, Bebington urban, Stockport, and Wilmslow urban 1 each); Suffolk, East, 5 (Lowestoft 1, Deben rural 4); Yorks, West Riding, 4 (Rothwell urban 2, Harrogate and Leeds 1 each); Middlesex 3, all in Harrow.

Scarlet Fever in 1939

In the last decade there has been a decline in the incidence of scarlet fever in England and Wales, Holland, France, and Hungary since 1934, in the United States of America since 1935, and in Ireland, Finland, Germany, and Rumania since 1936. In the first six months of 1939 a decline compared with 1938 has been observed in England and Wales, Belgium, Holland, Switzerland, Poland, and Yugoslavia, but increases have been reported in Sweden, Germany, Rumania, and Bulgaria. In the United States scarlet fever was lower during the four weeks ended August 12, 1939, than the median level for the thirteen-year period 1926–38.

Measles in U.S.A.
